Table of Contents

What is Aurora?	1
Aurora DB clusters	3
Aurora versions	5
Relational databases that are available on Aurora	5
Differences in version numbers between community databases and Aurora	5
Amazon Aurora major versions	6
Amazon Aurora minor versions	7
Amazon Aurora patch versions	7
Learning what's new in each Amazon Aurora version	7
Specifying the Amazon Aurora database version for your database cluster	7
Default Amazon Aurora versions	7
Automatic minor version upgrades	8
How long Amazon Aurora major versions remain available	8
How often Amazon Aurora minor versions are released	9
How long Amazon Aurora minor versions remain available	9
Long-term support for selected Amazon Aurora minor versions	9
Manually controlling if and when your database cluster is upgraded to new versions	9
Required Amazon Aurora upgrades	10
Testing your DB cluster with a new Aurora version before upgrading	10
Regions and Availability Zones	11
AWS Regions	11
Availability Zones	15
Local time zone for DB clusters	16
Supported Aurora features by Region and engine	19
Backtracking in Aurora	19
Aurora global databases	21
Aurora machine learning	23
Aurora parallel queries	26
Amazon RDS Proxy	27
Aurora Serverless v1	29
Data API for Aurora Serverless	31
Aurora connection management	32
Types of Aurora endpoints	33
Viewing endpoints	35
Using the cluster endpoint	35
Using the reader endpoint	35
Using custom endpoints	36
Creating a custom endpoint	38
Viewing custom endpoints	40
Editing a custom endpoint	45
Deleting a custom endpoint	47
End-to-end AWS CLI example for custom endpoints	48
Using the instance endpoints	52
Endpoints and high availability	52
DB instance classes	54
DB instance class types	54
Supported DB engines	54
Determining DB instance class support in AWS Regions	59
Hardware specifications	62
Aurora storage and reliability	64
Overview of Aurora storage	64
Cluster volume contents	65
How storage resizes	65
Data billing	65

Reliability	66
Aurora security	67
Using SSL with Aurora DB clusters	68
High availability for Amazon Aurora	68
High availability for Aurora data	68
High availability for Aurora DB instances	68
High availability across AWS Regions with Aurora global databases	69
Fault tolerance	69
Replication with Aurora	70
Aurora Replicas	70
Aurora MySQL	71
Aurora PostgreSQL	72
DB instance billing for Aurora	72
On-Demand DB instances	74
Reserved DB instances	75
Setting up your environment	84
Sign up for AWS	84
Create an IAM user	84
Determine requirements	86
Provide access to the DB cluster	87
Getting started	89
Creating an Aurora MySQL DB cluster and connecting to it	89
Create an Aurora MySQL DB cluster	89
Connect to an instance in a DB cluster	94
Delete the sample DB cluster, DB subnet group, and VPC	96
Creating an Aurora PostgreSQL DB cluster and connecting to it	96
Create an Aurora PostgreSQL DB cluster	97
Connect to an instance in an Aurora PostgreSQL DB cluster	101
Delete the sample DB cluster, DB subnet group, and VPC	102
Tutorial: Create a web server and an Amazon Aurora DB cluster	103
Create a DB cluster	104
Create a web server	109
Tutorials and sample code	121
Tutorials in this guide	121
Tutorials in other AWS guides	121
Tutorials and sample code in GitHub	122
Configuring your Aurora DB cluster	124
Creating a DB cluster	125
Prerequisites	125
Creating a DB cluster	126
Available settings	137
Creating resources with AWS CloudFormation	146
Aurora and AWS CloudFormation templates	146
Learn more about AWS CloudFormation	146
Using Aurora Serverless v1	147
Advantages of Aurora Serverless v1	147
Use cases for Aurora Serverless v1	148
Limitations of Aurora Serverless v1	148
Configuration requirements for Aurora Serverless v1	149
Using TLS/SSL with Aurora Serverless v1	150
How Aurora Serverless v1 works	151
Creating an Aurora Serverless v1 DB cluster	161
Restoring an Aurora Serverless v1 DB cluster	166
Modifying an Aurora Serverless v1 DB cluster	170
Scaling Aurora Serverless v1 DB cluster capacity manually	172
Viewing Aurora Serverless v1 DB clusters	174
Deleting an Aurora Serverless v1 DB cluster	175

Aurora Serverless v1 and Aurora database engine versions	177
Using the Data API	178
Logging Data API calls with AWS CloudTrail	202
Using the query editor	204
Using Aurora Serverless v2 (preview)	212
How Aurora Serverless v2 (preview) works	212
Limitations of Aurora Serverless v2 (preview)	215
Creating an Aurora Serverless v2 (preview) DB cluster	216
Creating a snapshot of an Aurora Serverless v2 (preview) DB cluster	219
Modifying an Aurora Serverless v2 (preview) DB cluster	220
Deleting an Aurora Serverless v2 (preview) DB cluster	222
Restoring an Aurora Serverless v2 (preview) DB cluster	223
Using Aurora global databases	225
Overview of Aurora global databases	225
Advantages of Amazon Aurora global databases	226
Limitations of Aurora global databases	226
Getting started with Aurora global databases	228
Managing an Aurora global database	249
Connecting to an Aurora global database	254
Using write forwarding in an Aurora global database	255
Using failover in an Aurora global database	266
Monitoring an Aurora global database	276
Using Aurora global databases with other AWS services	279
Upgrading an Amazon Aurora global database	280
Connecting to a DB cluster	281
Connecting to Aurora MySQL	281
Connecting to Aurora PostgreSQL	285
Troubleshooting connections	287
Using RDS Proxy	288
Supported engines and Region availability	288
Quotas and limitations	288
Planning where to use RDS Proxy	290
RDS Proxy concepts and terminology	290
Getting started with RDS Proxy	295
Managing an RDS Proxy	306
Working with RDS Proxy endpoints	315
Monitoring RDS Proxy with CloudWatch	324
Working with RDS Proxy events	329
RDS Proxy examples	330
Troubleshooting RDS Proxy	332
Using RDS Proxy with AWS CloudFormation	337
Working with parameter groups	339
DB cluster and DB instance parameters	341
Creating a DB parameter group	342
Creating a DB cluster parameter group	343
Associating a DB parameter group with a DB instance	345
Associating a DB cluster parameter group with a DB cluster	346
Modifying parameters in a DB parameter group	347
Modifying parameters in a DB cluster parameter group	349
Resetting parameters in a DB parameter group	351
Resetting parameters in a DB cluster parameter group	353
Copying a DB parameter group	354
Copying a DB cluster parameter group	356
Listing DB parameter groups	357
Listing DB cluster parameter groups	358
Viewing parameter values for a DB parameter group	359
Viewing parameter values for a DB cluster parameter group	360

Comparing parameter groups	362
Specifying DB parameters	362
Migrating data to a DB cluster	366
Aurora MySQL	366
Aurora PostgreSQL	366
Managing an Aurora DB cluster	367
Stopping and starting a cluster	368
Overview of stopping and starting a cluster	368
Limitations	368
Stopping a DB cluster	369
While a DB cluster is stopped	370
Starting a DB cluster	370
Modifying an Aurora DB cluster	372
Modifying the DB cluster by using the console, CLI, and API	372
Modify a DB instance in a DB cluster	373
Available settings	375
Non-applicable settings	390
Adding Aurora Replicas	392
Managing performance and scaling	396
Storage scaling	396
Instance scaling	400
Read scaling	400
Managing connections	400
Managing query execution plans	401
Cloning a volume for an Aurora DB cluster	402
Overview of Aurora cloning	402
Limitations of Aurora cloning	403
How Aurora cloning works	403
Creating an Aurora clone	406
Cross-account cloning	415
Integrating with AWS services	426
Aurora MySQL	426
Aurora PostgreSQL	426
Using Auto Scaling with Aurora replicas	427
Using machine learning with Aurora	442
Maintaining an Aurora DB cluster	443
Viewing pending maintenance	443
Applying updates	445
The maintenance window	446
Adjusting the maintenance window for a DB cluster	448
Automatic minor version upgrades for Aurora DB clusters	449
Choosing the frequency of Aurora MySQL maintenance updates	449
Rebooting an Aurora DB cluster or instance	451
Rebooting a DB instance within an Aurora cluster	451
Rebooting an Aurora cluster (Aurora PostgreSQL and Aurora MySQL before version 2.10)	452
Rebooting an Aurora MySQL cluster (version 2.10 and higher)	452
Checking uptime for Aurora clusters and instances	453
Examples of Aurora reboot operations	455
Deleting Aurora clusters and instances	467
Deleting an Aurora DB cluster	467
Deletion protection for Aurora clusters	471
Deleting a stopped Aurora cluster	472
Deleting Aurora MySQL clusters that are read replicas	472
The final snapshot when deleting a cluster	472
Deleting a DB instance from an Aurora DB cluster	472
Tagging RDS resources	474
Overview	474

Using tags for access control with IAM	475
Using tags to produce detailed billing reports	475
Adding, listing, and removing tags	476
Using the AWS Tag Editor	478
Copying tags to DB cluster snapshots	478
Tutorial: Use tags to specify which Aurora DB clusters to stop	479
Working with ARNs	482
Constructing an ARN	482
Getting an existing ARN	485
Aurora updates	489
Identifying your Amazon Aurora version	489
Backing up and restoring an Aurora DB cluster	490
Overview of backing up and restoring	491
Backups	491
Backup window	491
Restoring data	493
Backtrack	493
Backup storage	494
Creating a DB cluster snapshot	495
Determining whether the snapshot is available	496
Restoring from a DB cluster snapshot	497
Parameter groups	497
Security groups	497
Aurora considerations	497
Restoring from a snapshot	498
Copying a snapshot	500
Limitations	500
Snapshot retention	500
Copying shared snapshots	501
Handling encryption	501
Incremental snapshot copying	501
Cross-Region copying	501

CloudWatch metrics for Aurora	633
CloudWatch dimensions for Aurora	649
Availability of Aurora metrics in the Amazon RDS console	649
CloudWatch metrics for Performance Insights	652
Counter metrics for Performance Insights	653
OS metrics in Enhanced Monitoring	660
Monitoring events, logs, and database activity streams	666
Viewing logs, events, and streams in the Amazon RDS console	666
Monitoring Aurora events	671
Overview of events for Aurora	671
Viewing Amazon RDS events	674
Using Amazon RDS event notification	675
Creating a rule that triggers on an Amazon Aurora event	692
Monitoring Aurora logs	695
Viewing and listing database log files	695
Downloading a database log file	696
Watching a database log file	697
Publishing to CloudWatch Logs	697
Reading log file contents using REST	698
MySQL database log files	700
PostgreSQL database log files	706
Monitoring Aurora API calls in CloudTrail	710
CloudTrail integration with Amazon Aurora	710
Amazon Aurora log file entries	710
Monitoring Aurora with Database Activity Streams	714
Overview	714
Aurora MySQL network prerequisites	717
Starting a database activity stream	718

Getting activity stream status	720
Stopping a database activity stream	720
Monitoring activity streams	721
Managing access to activity streams	743
Working with Aurora MySQL	746
Overview of Aurora MySQL	746
Amazon Aurora MySQL performance enhancements	746
Aurora MySQL and spatial data	747
Aurora MySQL version 3 compatible with MySQL 8.0	748
Aurora MySQL version 2 compatible with MySQL 5.7	773
Security with Aurora MySQL	774
Master user privileges with Aurora MySQL	775
Using SSL/TLS with Aurora MySQL DB clusters	775
Updating applications for new SSL/TLS certificates	778
Determining whether any applications are connecting to your Aurora MySQL DB cluster using SSL	778
Determining whether a client requires certificate verification to connect	779
Updating your application trust store	780
Example Java code for establishing SSL connections	781
Migrating data to Aurora MySQL	781
Migrating from an external MySQL database to Aurora MySQL	784
Migrating from a MySQL DB instance to Aurora MySQL	797
Managing Aurora MySQL	812
Managing performance and scaling for Amazon Aurora MySQL	812
Backtracking a DB cluster	816
Testing Amazon Aurora using fault injection queries	829
Altering tables in Amazon Aurora using fast DDL	832
Displaying volume status for an Aurora DB cluster	837
Tuning Aurora MySQL with wait events and thread states	837
Essential concepts for Aurora MySQL tuning	838
Tuning Aurora MySQL with wait events	840
Tuning Aurora MySQL with thread states	876
Parallel query for Aurora MySQL	881
Overview of parallel query	883
Planning for a parallel query cluster	885
Creating a parallel query cluster	886
Turning parallel query on and off	890
Upgrading a parallel query cluster	893
Performance tuning	894
Creating schema objects	895
Verifying parallel query usage	895
Monitoring	898
Parallel query and SQL constructs	901
Advanced Auditing with Aurora MySQL	914
Enabling Advanced Auditing	915
Viewing audit logs	917
Audit log details	917
Single-master replication with Aurora MySQL	918
Aurora replicas	918
Options	919
Performance	920
Zero-downtime restart (ZDR)	920
Monitoring	922
Replicating Amazon Aurora MySQL DB clusters across AWS Regions	922
Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)	932
Using GTID-based replication	954

Working with multi-master clusters	958
Overview of multi-master clusters	958
Creating a multi-master cluster	963
Managing multi-master clusters	969
Application considerations	972
Performance considerations	981
Approaches to multi-master clusters	983

What is Amazon Aurora?

Amazon Aurora (Aurora) is a fully managed relational database engine that's compatible with MySQL and PostgreSQL. You already know how MySQL and PostgreSQL combine the speed and reliability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases. The code, tools, and applications you use today with your existing MySQL and PostgreSQL databases can be used with Aurora. With some workloads, Aurora can deliver up to five times the throughput of MySQL and up to three times the throughput of PostgreSQL without requiring changes to most of your existing applications.

Aurora includes a high-performance storage subsystem. Its MySQL- and PostgreSQL-compatible database engines are customized to take advantage of that fast distributed storage. The underlying storage grows automatically as needed. An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB). Aurora also automates and standardizes database clustering and replication, which are typically among the most challenging aspects of database configuration and administration.

Aurora is part of the managed database service Amazon Relational Database Service (Amazon RDS). Amazon RDS is a web service that makes it easier to set up, operate, and scale a relational database in the cloud. If you are not already familiar with Amazon RDS, see the [Amazon Relational Database Service User Guide](#).

The following points illustrate how Aurora relates to the standard MySQL and PostgreSQL engines available in Amazon RDS:

- You choose Aurora as the DB engine option when setting up new database servers through Amazon RDS.
- Aurora takes advantage of the familiar Amazon Relational Database Service (Amazon RDS) features for management and administration. Aurora uses the Amazon RDS AWS Management Console interface, AWS CLI commands, and API operations to handle routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair.
- Aurora management operations typically involve entire clusters of database servers that are synchronized through replication, instead of individual database instances. The automatic clustering, replication, and storage allocation make it simple and cost-effective to set up, operate, and scale your largest MySQL and PostgreSQL deployments.
- You can bring data from Amazon RDS for MySQL and Amazon RDS for PostgreSQL into Aurora by creating and restoring snapshots, or by setting up one-way replication. You can use push-button migration tools to convert your existing Amazon RDS for MySQL and Amazon RDS for PostgreSQL applications to Aurora.

Before using Amazon Aurora, you should complete the steps in [Setting up your environment for Amazon Aurora \(p. 84\)](#), and then review the concepts and features of Aurora in [Amazon Aurora DB clusters \(p. 3\)](#).

Amazon Aurora DB clusters

An Amazon Aurora *DB cluster* consists of one or more DB instances and a cluster volume that manages the data for those DB instances. An Aurora *cluster volume* is a virtual database storage volume that spans multiple Availability Zones, with each Availability Zone having a copy of the DB cluster data. Two types of DB instances make up an Aurora DB cluster:

- **Primary DB instance** – Supports read and write operations, and performs all of the data modifications to the cluster volume. Each Aurora DB cluster has one primary DB instance.
- **Aurora Replica** – Connects to the same storage volume as the primary DB instance and supports only read operations. Each Aurora DB cluster can have up to 15 Aurora Replicas in addition to the primary DB instance. Maintain high availability by locating Aurora Replicas in separate Availability Zones. Aurora automatically fails over to an Aurora Replica in case the primary DB instance becomes unavailable. You can specify the failover priority for Aurora Replicas. Aurora Replicas can also offload read workloads from the primary DB instance.

The following diagram illustrates the relationship between the cluster volume, the primary DB instance, and Aurora Replicas in an Aurora DB cluster.

Note

The preceding information applies to all the Aurora clusters that use single-master replication. These include provisioned clusters, parallel query clusters, global database clusters, serverless clusters, and all MySQL 8.0-compatible, 5.7-compatible, and PostgreSQL-compatible clusters. Aurora clusters that use multi-master replication have a different arrangement of read/write and read-only DB instances. All DB instances in a multi-master cluster can perform write operations. There isn't a single DB instance that performs all the write operations, and there aren't any read-only DB instances. Therefore, the terms *primary instance* and *Aurora Replica* don't apply to multi-master clusters. When we discuss clusters that might use multi-master replication, we refer to *writer* DB instances and *reader* DB instances.

The Aurora cluster illustrates the separation of compute capacity and storage. For example, an Aurora configuration with only a single DB instance is still a cluster, because the underlying storage volume involves multiple storage nodes distributed across multiple Availability Zones (AZs).

Amazon Aurora versions

Amazon Aurora reuses code and maintains compatibility with the underlying MySQL and PostgreSQL DB engines. However, Aurora has its own version numbers, release cycle, time line for version deprecation and end of life, and so on. The following section explains the common points and differences. This information can help you to decide such things as which version to choose and how to verify which features and fixes are available in each version. It can also help you to decide how often to upgrade and how to plan your upgrade process.

Relational databases that are available on Aurora

The following relational databases are available on Aurora:

- Amazon Aurora MySQL-Compatible Edition. For usage information, see [Working with Amazon Aurora MySQL \(p. 746\)](#). For a detailed list of available versions, see [Database engine updates for Amazon Aurora MySQL \(p. 1082\)](#).
- Amazon Aurora PostgreSQL-Compatible Edition. For usage information, see [Working with Amazon Aurora PostgreSQL \(p. 1275\)](#). For a detailed list of available versions, see [Amazon Aurora PostgreSQL updates \(p. 1597\)](#).

Differences in version numbers between community databases and Aurora

Each Amazon Aurora version is compatible with a specific community database version of either MySQL or PostgreSQL. You can find the community version of your database using the `version` function and the Aurora version using the `aurora_version` function.

Examples for Aurora MySQL and Aurora PostgreSQL are shown following.

```
mysql> select version();
+-----+
| version()      |
+-----+
| 5.7.12         |
+-----+

mysql> select aurora_version(), @@aurora_version;
+-----+-----+
| aurora_version() | @@aurora_version |
+-----+-----+
| 2.08.1          | 2.08.1           |
+-----+-----+
```

```
postgres=> select version();
-----
PostgreSQL 11.7 on x86_64-pc-linux-gnu, compiled by gcc (GCC) 4.9.3, 64-bit
(1 row)

postgres=> select aurora_version();
aurora_version
-----
3.2.2
```

For more information, see [Checking Aurora MySQL versions using SQL \(p. 1084\)](#) and [Identifying versions of Amazon Aurora PostgreSQL \(p. 1598\)](#).

Amazon Aurora major versions

Aurora versions use the *major.minor.patch* scheme. An *Aurora major version* refers to the MySQL or PostgreSQL community major version that Aurora is compatible with. The following example shows the mapping between community MySQL and PostgreSQL versions and the corresponding Aurora versions.

Community major version	Aurora major version
MySQL 5.6	Aurora MySQL 1
MySQL 5.7	Aurora MySQL 2
MySQL 8.0	Aurora MySQL 3
PostgreSQL 9.6	Aurora PostgreSQL 1
PostgreSQL 10	Aurora PostgreSQL 2. Not applicable for version 10.18 and higher versions. For these versions, the Aurora version is the same as the <i>major.minor</i> version of the PostgreSQL community version and a third digit in <i>patch</i> location.
PostgreSQL 11	Aurora PostgreSQL 3. Not applicable for version 11.13 and higher versions. For these versions, the Aurora version is the same as the <i>major.minor</i> version of the PostgreSQL community version and a third digit in <i>patch</i> location.
PostgreSQL 12	Aurora PostgreSQL 4. Not applicable for version 12.8 and higher versions. For these versions, the Aurora version is the same as the <i>major.minor</i>

Community major version	Aurora major version
	version of the PostgreSQL community version and a third digit in <i>patch</i> location.
PostgreSQL 13	Aurora PostgreSQL 4. Not applicable for version 13.3 and higher versions. For these versions, the Aurora version is the same as the <i>major.minor</i> version of the PostgreSQL community version and a third digit in <i>patch</i> location.

Amazon Aurora minor versions

Aurora versions use the *major.minor.patch* scheme. An *Aurora minor version* provides incremental community and Aurora-specific improvements to the service, for example new features and bug fixes.

Aurora minor versions are always mapped to a specific community version. However, some community versions might not have an Aurora equivalent.

Amazon Aurora patch versions

Aurora versions use the *major.minor.patch* scheme. An Aurora patch version includes important bug fixes added to a minor version after its initial release (for example, Aurora MySQL 2.04.0, 2.04.1, ..., 2.04.9). While each new minor version provides new Aurora features, new patch versions within a specific minor version are primarily used to resolve important issues.

For more information on patching, see [Maintaining an Amazon Aurora DB cluster \(p. 443\)](#).

Learning what's new in each Amazon Aurora version

Each new Aurora version comes with release notes that list the new features, fixes, other enhancements, and so on that apply to each version.

For Aurora MySQL release notes, see [Database engine updates for Amazon Aurora MySQL version 2 \(p. 1108\)](#) and [Database engine updates for Amazon Aurora MySQL version 1 \(p. 1196\)](#). For Aurora PostgreSQL release notes, see [Amazon Aurora PostgreSQL releases and engine versions \(p. 1599\)](#).

Specifying the Amazon Aurora database version for your database cluster

You can specify any currently available version (major and minor) when creating a new DB cluster using the **Create database** operation in the AWS Management Console, the AWS CLI, or the `CreateDBCluster` API operation. Not every Aurora database version is available in every AWS Region.

To learn how to create Aurora clusters, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#). To learn how to change the version of an existing Aurora cluster, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

Default Amazon Aurora versions

When a new Aurora minor version contains significant improvements compared to a previous one, it's marked as the default version for new DB clusters. Typically, we release two default versions for each major version per year.

We recommend that you keep your DB cluster upgraded to the most current default minor version, because that version contains the latest security and functionality fixes.

Automatic minor version upgrades

You can stay up to date with Aurora minor versions by turning on **Auto minor version upgrade** for every DB instance in the Aurora cluster. Aurora only performs the automatic upgrade if all DB instances in your cluster have this setting turned on. Auto minor version upgrades are performed to the default minor version. We typically schedule automatic upgrades twice a year for DB clusters that have the **Auto minor version upgrade** setting set to **Yes**. These upgrades are started during the maintenance window that you specify for your cluster.

For more information, see [Enabling automatic upgrades between minor Aurora MySQL versions \(p. 1089\)](#) and [Automatic minor version upgrades for PostgreSQL \(p. 1688\)](#).

How long Amazon Aurora major versions remain available

Amazon Aurora major versions are made available at least until community end of life for the corresponding community version. You can use the following dates to plan your testing and upgrade cycles. These dates represent the minimum support period for each Aurora version. If Amazon extends support for an Aurora version for longer than originally planned, we plan to update this table to reflect the later date.

Database community version	Aurora version	Aurora version end of life no earlier than
MySQL 5.6	1	February 28, 2023, 00:00:00 UTC
MySQL 5.7	2	February 29, 2024
MySQL 8.0	3	
PostgreSQL 9.6	1	January 31, 2022
PostgreSQL 10	Varies depending on the minor version of the Aurora PostgreSQL release. For more information, see Amazon Aurora major versions (p. 6) .	January 31, 2023
PostgreSQL 11		January 31, 2024
PostgreSQL 12		January 31, 2025
PostgreSQL 13		January 31, 2026

Before each Aurora major version end of life, we provide a reminder at least 12 months in advance. We do so to communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take. We always recommend that you thoroughly test your applications against new database versions before performing a major version upgrade.

After this 12-month period, an automatic upgrade to the subsequent major version might be applied to any database cluster still running the older version. If so, the upgrade is started during scheduled maintenance windows.

How often Amazon Aurora minor versions are released

In general, Amazon Aurora minor versions are released quarterly. The release schedule might vary to pick up additional features or fixes.

How long Amazon Aurora minor versions remain available

We intend to make each Amazon Aurora minor version of a particular major version available for at least 12 months. At the end of this period, Aurora might apply an auto minor version upgrade to the subsequent default minor version. Such an upgrade is started during the scheduled maintenance window for any cluster that is still running the older minor version.

We might replace a minor version of a particular major version sooner than the usual 12-month period if there are critical matters such as security issues, or if the major version has reached end of life.

Before beginning automatic upgrades of minor versions that are approaching end of life, we generally provide a reminder three months in advance. We do so to communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take.

Long-term support for selected Amazon Aurora minor versions

For each Aurora major version, certain minor versions are designated as long-term-support (LTS) versions and made available for at least three years. That is, at least one minor version per major version is made available for longer than the typical 12 months. We generally provide a reminder six months before the end of this period. We do so to communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take.

LTS minor versions include only bug fixes (through patch versions). An LTS version doesn't include new features released after its introduction. Once a year, DB clusters running on an LTS minor version are patched to the latest patch version of the LTS release. We do this patching to help ensure that you benefit from cumulative security and stability fixes. We might patch an LTS minor version more frequently if there are critical fixes, such as for security, that need to be applied.

Note

If you want to remain on an LTS minor version for the duration of its lifecycle, make sure to turn off **Auto minor version upgrade** for your DB instances. To avoid automatically upgrading your DB cluster from the LTS minor version, set **Auto minor version upgrade** to **No** on all DB instances in your Aurora cluster.

For the version numbers of all Aurora LTS versions, see [Aurora MySQL long-term support \(LTS\) releases \(p. 1085\)](#) and [Aurora PostgreSQL long-term support \(LTS\) releases \(p. 1690\)](#).

Manually controlling if and when your database cluster is upgraded to new versions

Auto minor version upgrades are performed to the default minor version. We typically schedule automatic upgrades twice a year for DB clusters that have the **Auto minor version upgrade** setting set to **Yes**. These upgrades are started during customer-specified maintenance windows. If you want to turn

off automatic minor version upgrades, set **Auto minor version upgrade** to **No** on any DB instance within an Aurora cluster. Aurora performs an automatic minor version upgrade only if all DB instances in your cluster have the setting turned on.

Because major version upgrades involve some compatibility risk, they don't occur automatically. You must initiate these, except in the case of a major version upgrade due to end of life, as explained earlier. We always recommend that you thoroughly test your applications with new database versions before performing a major version upgrade.

For more information about upgrading a DB cluster to a new Aurora major version, see [Upgrading Amazon Aurora MySQL DB clusters \(p. 1088\)](#) and [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL \(p. 1681\)](#).

Required Amazon Aurora upgrades

For certain critical fixes, we might perform a managed upgrade to a newer patch level within the same minor version. These required upgrades happen even if **Auto minor version upgrade** is turned off. Before doing so, we communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take. Such managed upgrades are performed automatically. Each such upgrade is started within the cluster maintenance window.

Testing your DB cluster with a new Aurora version before upgrading

You can test the upgrade process and how the new version works with your application and workload. Use one of the following methods:

- Clone your cluster using the Amazon Aurora fast database clone feature. Perform the upgrade and any post-upgrade testing on the new cluster.
- Restore from a cluster snapshot to create a new Aurora cluster. You can create a cluster snapshot yourself from an existing Aurora cluster. Aurora also automatically creates periodic snapshots for you for each of your clusters. You can then initiate a version upgrade for the new cluster. You can experiment on the upgraded copy of your cluster before deciding whether to upgrade your original cluster.

For more information on these ways to create new clusters for testing, see [Cloning a volume for an Aurora DB cluster \(p. 402\)](#) and [Creating a DB cluster snapshot \(p. 495\)](#).

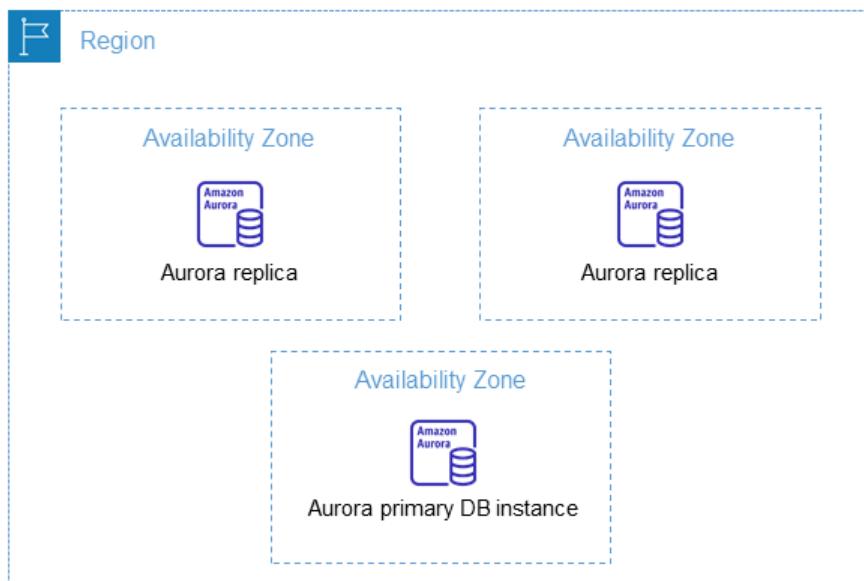

Regions and Availability Zones

Amazon cloud computing resources are hosted in multiple locations world-wide. These locations are composed of AWS Regions and Availability Zones. Each *AWS Region* is a separate geographic area. Each AWS Region has multiple, isolated locations known as *Availability Zones*.

Note

For information about finding the Availability Zones for an AWS Region, see [Describe Your Availability Zones](#) in the Amazon EC2 documentation.

Amazon operates state-of-the-art, highly-available data centers. Although rare, failures can occur that affect the availability of DB instances that are in the same location. If you host all your DB instances in a single location that is affected by such a failure, none of your DB instances will be available.

It is important to remember that each AWS Region is completely independent. Any Amazon RDS activity you initiate (for example, creating database instances or listing available database instances) runs only in your current default AWS Region. The default AWS Region can be changed in the console, by setting the `AWS_DEFAULT_REGION` environment variable, or it can be overridden by using the `--region` parameter with the AWS Command Line Interface (AWS CLI). For more information, see [Configuring the AWS Command Line Interface](#), specifically the sections about environment variables and command line options.

Amazon RDS supports special AWS Regions called AWS GovCloud (US) that are designed to allow US government agencies and customers to move more sensitive workloads into the cloud. The AWS GovCloud (US) Regions address the US government's specific regulatory and compliance requirements. For more information, see [What is AWS GovCloud \(US\)?](#)

To create or work with an Amazon RDS DB instance in a specific AWS Region, use the corresponding regional service endpoint.

Note

Aurora doesn't support Local Zones.

AWS Regions

Each AWS Region is designed to be isolated from the other AWS Regions. This design achieves the greatest possible fault tolerance and stability.

When you view your resources, you see only the resources that are tied to the AWS Region that you specified. This is because AWS Regions are isolated from each other, and we don't automatically replicate resources across AWS Regions.

Region availability

When you work with an Aurora DB cluster using the command line interface or API operations, make sure that you specify its regional endpoint.

Topics

- [Aurora MySQL Region availability \(p. 12\)](#)
- [Aurora PostgreSQL Region availability \(p. 14\)](#)

Aurora MySQL Region availability

The following table shows the AWS Regions where Aurora MySQL is currently available and the endpoint for each Region.

Region Name	Region	Endpoint	Protocol	
US East (Ohio)	us-east-2	rds.us-east-2.amazonaws.com	HTTPS	
US East (N. Virginia)	us-east-1	rds.us-east-1.amazonaws.com	HTTPS	
US West (N. California)	us-west-1	rds.us-west-1.amazonaws.com	HTTPS	
US West (Oregon)	us-west-2	rds.us-west-2.amazonaws.com	HTTPS	
Africa (Cape Town)	af-south-1	rds.af-south-1.amazonaws.com	HTTPS	
Asia Pacific (Hong Kong)	ap-east-1	rds.ap-east-1.amazonaws.com	HTTPS	
Asia Pacific (Jakarta)	ap-southeast-3	rds.ap-southeast-3.amazonaws.com	HTTPS	
Asia Pacific (Mumbai)	ap-south-1	rds.ap-south-1.amazonaws.com	HTTPS	
Asia Pacific (Osaka)	ap-northeast-3	rds.ap-northeast-3.amazonaws.com	HTTPS	

Region Name	Region	Endpoint	Protocol	
Asia Pacific (Seoul)	ap-northeast-2	rds.ap-northeast-2.amazonaws.com	HTTPS	
Asia Pacific (Singapore)	ap-southeast-1	rds.ap-southeast-1.amazonaws.com	HTTPS	
Asia Pacific (Sydney)	ap-southeast-2	rds.ap-southeast-2.amazonaws.com	HTTPS	
Asia Pacific (Tokyo)	ap-northeast-1	rds.ap-northeast-1.amazonaws.com	HTTPS	
Canada (Central)	ca-central-1	rds.ca-central-1.amazonaws.com	HTTPS	
Europe (Frankfurt)	eu-central-1	rds.eu-central-1.amazonaws.com	HTTPS	
Europe (Ireland)	eu-west-1	rds.eu-west-1.amazonaws.com	HTTPS	
Europe (London)	eu-west-2	rds.eu-west-2.amazonaws.com	HTTPS	
Europe (Milan)	eu-south-1	rds.eu-south-1.amazonaws.com	HTTPS	
Europe (Paris)	eu-west-3	rds.eu-west-3.amazonaws.com	HTTPS	
Europe (Stockholm)	eu-north-1	rds.eu-north-1.amazonaws.com	HTTPS	
Middle East (Bahrain)	me-south-1	rds.me-south-1.amazonaws.com	HTTPS	
South America (São Paulo)	sa-east-1	rds.sa-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-East)	us-gov-east-1	rds.us-gov-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-West)	us-gov-west-1	rds.us-gov-west-1.amazonaws.com	HTTPS	

Aurora PostgreSQL Region availability

The following table shows the AWS Regions where Aurora PostgreSQL is currently available and the endpoint for each Region.

Region Name	Region	Endpoint	Protocol	
US East (Ohio)	us-east-2	rds.us-east-2.amazonaws.com	HTTPS	
US East (N. Virginia)	us-east-1	rds.us-east-1.amazonaws.com	HTTPS	
US West (N. California)	us-west-1	rds.us-west-1.amazonaws.com	HTTPS	
US West (Oregon)	us-west-2	rds.us-west-2.amazonaws.com	HTTPS	
Africa (Cape Town)	af-south-1	rds.af-south-1.amazonaws.com	HTTPS	
Asia Pacific (Hong Kong)	ap-east-1	rds.ap-east-1.amazonaws.com	HTTPS	
Asia Pacific (Jakarta)	ap-southeast-3	rds.ap-southeast-3.amazonaws.com	HTTPS	
Asia Pacific (Mumbai)	ap-south-1	rds.ap-south-1.amazonaws.com	HTTPS	
Asia Pacific (Osaka)	ap-northeast-3	rds.ap-northeast-3.amazonaws.com	HTTPS	
Asia Pacific (Seoul)	ap-northeast-2	rds.ap-northeast-2.amazonaws.com	HTTPS	
Asia Pacific (Singapore)	ap-southeast-1	rds.ap-southeast-1.amazonaws.com	HTTPS	
Asia Pacific (Sydney)	ap-southeast-2	rds.ap-southeast-2.amazonaws.com	HTTPS	
Asia Pacific (Tokyo)	ap-northeast-1	rds.ap-northeast-1.amazonaws.com	HTTPS	

Region Name	Region	Endpoint	Protocol	
Canada (Central)	ca-central-1	rds.ca-central-1.amazonaws.com	HTTPS	
Europe (Frankfurt)	eu-central-1	rds.eu-central-1.amazonaws.com	HTTPS	
Europe (Ireland)	eu-west-1	rds.eu-west-1.amazonaws.com	HTTPS	
Europe (London)	eu-west-2	rds.eu-west-2.amazonaws.com	HTTPS	
Europe (Milan)	eu-south-1	rds.eu-south-1.amazonaws.com	HTTPS	
Europe (Paris)	eu-west-3	rds.eu-west-3.amazonaws.com	HTTPS	
Europe (Stockholm)	eu-north-1	rds.eu-north-1.amazonaws.com	HTTPS	
Middle East (Bahrain)	me-south-1	rds.me-south-1.amazonaws.com	HTTPS	
South America (São Paulo)	sa-east-1	rds.sa-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-East)	us-gov-east-1	rds.us-gov-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-West)	us-gov-west-1	rds.us-gov-west-1.amazonaws.com	HTTPS	

Availability Zones

An Availability Zone is an isolated location in a given AWS Region. Each Region has multiple Availability Zones (AZ) designed to provide high availability for the Region. An AZ is identified by the AWS Region code followed by a letter identifier (for example, `us-east-1a`). If you create your VPC and subnets rather than using the default VPC, you define each subnet in a specific AZ. When you create an Aurora DB cluster, Aurora creates the primary instance in one of the subnets in the VPC's DB subnet group, thus associating that instance with a specific AZ chosen by Aurora.

Each Aurora DB cluster hosts copies of its storage in three separate AZs. Every DB instance in the cluster must be in one of these three AZs. When you create a DB instance in your cluster, Aurora automatically chooses an appropriate AZ if you don't specify an AZ. If an AWS Region has fewer than three AZs, Aurora isn't available in that Region.

To learn how to specify the AZ when you create a cluster or add instances to it, see [VPC, subnets, and AZs \(p. 125\)](#).

Local time zone for Amazon Aurora DB clusters

By default, the time zone for an Amazon Aurora DB cluster is Universal Time Coordinated (UTC). You can set the time zone for instances in your DB cluster to the local time zone for your application instead.

To set the local time zone for a DB cluster, set the time zone parameter in the cluster parameter group for your DB cluster to one of the supported values listed later in this section. For Aurora MySQL, the name of this parameter is `time_zone`. For Aurora PostgreSQL, the name of this parameter is `timezone`. When you set the time zone parameter for a DB cluster, all instances in the DB cluster change to use the new local time zone. If other Aurora DB clusters are using the same cluster parameter group, then all instances in those DB clusters change to use the new local time zone also. For information on cluster-level parameters, see [Amazon Aurora DB cluster and DB instance parameters \(p. 341\)](#).

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

If you are replicating across AWS Regions, then the replication master DB cluster and the replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the time zone parameter in the parameter groups for both the replication master and the replica.

When you restore a DB cluster from a DB cluster snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB cluster to a point in time, then the local time zone for the restored DB cluster is the time zone setting from the parameter group of the restored DB cluster.

You can set your local time zone to one of the values listed in the following table. For some time zones, time values for certain date ranges can be reported incorrectly as noted in the table. For Australia time zones, the time zone abbreviation returned is an outdated value as noted in the table.

Time zone	Notes
Africa/Harare	This time zone setting can return incorrect values from 28 Feb 1903 21:49:40 GMT to 28 Feb 1903 21:55:48 GMT.
Africa/Monrovia	
Africa/Nairobi	This time zone setting can return incorrect values from 31 Dec 1939 21:30:00 GMT to 31 Dec 1959 21:15:15 GMT.
Africa/Windhoek	
America/Bogota	This time zone setting can return incorrect values from 23 Nov 1914 04:56:16 GMT to 23 Nov 1914 04:56:20 GMT.
America/Caracas	
America/Chihuahua	
America/Cuiaba	
America/Denver	
America/Fortaleza	If your DB cluster is in the South America (Sao Paulo) Region and the expected time doesn't show correctly for the recently changed Brazil time zone, reset the DB cluster's time zone parameter to <code>America/Fortaleza</code> .
America/Guatemala	

Time zone	Notes
America/Halifax	This time zone setting can return incorrect values from 27 Oct 1918 05:00:00 GMT to 31 Oct 1918 05:00:00 GMT.
America/Manaus	If your DB cluster is in the South America (Cuiaba) time zone and the expected time doesn't show correctly for the recently changed Brazil time zone, reset the DB cluster's time zone parameter to America/Manaus.
America/Matamoros	
America/Monterrey	
America/Montevideo	
America/Phoenix	
America/Tijuana	
Asia/Ashgabat	
Asia/Baghdad	
Asia/Baku	
Asia/Bangkok	
Asia/Beirut	
Asia/Calcutta	
Asia/Kabul	
Asia/Karachi	
Asia/Kathmandu	
Asia/Muscat	This time zone setting can return incorrect values from 31 Dec 1919 20:05:36 GMT to 31 Dec 1919 20:05:40 GMT.
Asia/Riyadh	This time zone setting can return incorrect values from 13 Mar 1947 20:53:08 GMT to 31 Dec 1949 20:53:08 GMT.

Supported features in Amazon Aurora by AWS Region and Aurora DB engine

Aurora MySQL- and PostgreSQL-compatible database engines support several Amazon Aurora and Amazon RDS features and options. The support varies across specific versions of each database engine, and across AWS Regions. You can use the tables in this section to identify Aurora database engine version support and availability in a given AWS Region for the following features:

Topics

- [Backtracking in Aurora \(p. 19\)](#)
- [Aurora global databases \(p. 21\)](#)
- [Aurora machine learning \(p. 23\)](#)
- [Aurora parallel queries \(p. 26\)](#)
- [Amazon RDS Proxy \(p. 27\)](#)
- [Aurora Serverless v1 \(p. 29\)](#)
- [Data API for Aurora Serverless \(p. 31\)](#)

Some of these features are Aurora-only capabilities. For example, Aurora Serverless, Aurora global databases, and support for integration with AWS machine learning services aren't supported by Amazon RDS. Other features, such as Amazon RDS Proxy, are supported by both Amazon Aurora and Amazon RDS.

The tables use the following patterns to specify version numbers and level of support:

- **Version x.y** – The specific version alone is supported.
- **Version x.y and higher** – The version and all minor versions are also supported. For example, "version 10.11 and higher" means that versions 10.11, 10.11.1, and 10.12 are also supported.
- - – The feature is not currently available for that particular Aurora feature for the given Aurora database engine, or in that specific AWS Region.

Backtracking in Aurora

By using backtracking in Aurora, you return the state of an Aurora cluster to a specific point in time, without restoring data from a backup. It completes within seconds, even for large databases. For more information, see [Backtracking an Aurora DB cluster \(p. 816\)](#).

Aurora backtracking is available for Aurora MySQL only. It's not available for Aurora PostgreSQL.

Aurora global databases

An *Aurora global database* is a single database that spans multiple AWS Regions, enabling low-latency global reads and disaster recovery from any Region-wide outage. It provides built-in fault tolerance for your deployment because the DB instance relies not on a single AWS Region, but upon multiple Regions and different Availability Zones.

Support for this feature varies by Aurora database engine and version. The following table shows the Regions and Aurora database versions that support this feature. For more information, see [Using Amazon Aurora global databases \(p. 225\)](#).

Aurora machine learning

Aurora machine learning provides simple, optimized, and secure integration between Aurora and AWS machine learning services without having to build custom integrations or move data around. Aurora exposes ML models as SQL functions, so you don't need to learn new programming languages or tools. Instead, you use standard SQL to build applications that call ML models, pass data to them, and return predictions as query results. For more information, see [Using machine learning \(ML\) capabilities with Amazon Aurora \(p. 442\)](#).

Aurora parallel queries

Aurora parallel queries can speed up your queries by up to two orders of magnitude, while maintaining high throughput for your core transactional workload. Using the unique Aurora architecture, parallel queries can push down and parallelize query processing across thousands of CPUs in the Aurora storage layer. By offloading analytical query processing to the Aurora storage layer, parallel queries reduce network, CPU, and buffer pool contention for transactional workloads. For more information, see [Working with parallel query for Amazon Aurora MySQL \(p. 881\)](#). To learn more about Aurora MySQL versions available for parallel queries and any steps you might need to take based on that version to support parallel queries, see [Planning for a parallel query cluster \(p. 885\)](#).

Aurora parallel queries are available for Aurora MySQL only. However, PostgreSQL has its own parallel query feature that is available on Amazon RDS. The capability is enabled by default when a new PostgreSQL instance is created (versions 10.1 and higher). For more information, see [PostgreSQL on Amazon RDS](#).

Aurora Serverless v1

Aurora Serverless v1 is an on-demand, auto-scaling feature designed to be a cost-effective approach to running intermittent or unpredictable workloads on Amazon Aurora. It automatically starts up, shuts

down, and scales capacity up or down, as needed by your applications. For more information, see [Using Amazon Aurora Serverless v1 \(p. 147\)](#).

Data API for Aurora Serverless

The Data API for Aurora Serverless provides a web-services interface to an Aurora Serverless cluster. Rather than managing database connections from client applications, you can run SQL commands against an HTTPS endpoint. For more information, see [Using the Data API for Aurora Serverless \(p. 178\)](#).

Amazon Aurora connection management

Amazon Aurora typically involves a cluster of DB instances instead of a single instance. Each connection is handled by a specific DB instance. When you connect to an Aurora cluster, the host name and port that you specify point to an intermediate handler called an *endpoint*. Aurora uses the endpoint mechanism to abstract these connections. Thus, you don't have to hardcode all the hostnames or write your own logic for load-balancing and rerouting connections when some DB instances aren't available.

For certain Aurora tasks, different instances or groups of instances perform different roles. For example, the primary instance handles all data definition language (DDL) and data manipulation language (DML) statements. Up to 15 Aurora Replicas handle read-only query traffic.

Using endpoints, you can map each connection to the appropriate instance or group of instances based on your use case. For example, to perform DDL statements you can connect to whichever instance is the

primary instance. To perform queries, you can connect to the reader endpoint, with Aurora automatically performing load-balancing among all the Aurora Replicas. For clusters with DB instances of different capacities or configurations, you can connect to custom endpoints associated with different subsets of DB instances. For diagnosis or tuning, you can connect to a specific instance endpoint to examine details about a specific DB instance.

Types of Aurora endpoints

An endpoint is represented as an Aurora-specific URL that contains a host address and a port. The following types of endpoints are available from an Aurora DB cluster.

Cluster endpoint

A *cluster endpoint* (or *writer endpoint*) for an Aurora DB cluster connects to the current primary DB instance for that DB cluster. This endpoint is the only one that can perform write operations such as DDL statements. Because of this, the cluster endpoint is the one that you connect to when you first set up a cluster or when your cluster only contains a single DB instance.

Each Aurora DB cluster has one cluster endpoint and one primary DB instance.

You use the cluster endpoint for all write operations on the DB cluster, including inserts, updates, deletes, and DDL changes. You can also use the cluster endpoint for read operations, such as queries.

The cluster endpoint provides failover support for read/write connections to the DB cluster. If the current primary DB instance of a DB cluster fails, Aurora automatically fails over to a new primary DB instance. During a failover, the DB cluster continues to serve connection requests to the cluster endpoint from the new primary DB instance, with minimal interruption of service.

The following example illustrates a cluster endpoint for an Aurora MySQL DB cluster.

```
mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com:3306
```

Reader endpoint

A *reader endpoint* for an Aurora DB cluster provides load-balancing support for read-only connections to the DB cluster. Use the reader endpoint for read operations, such as queries. By processing those statements on the read-only Aurora Replicas, this endpoint reduces the overhead on the primary instance. It also helps the cluster to scale the capacity to handle simultaneous

`SELECT` queries, proportional to the number of Aurora Replicas in the cluster. Each Aurora DB cluster has one reader endpoint.

If the cluster contains one or more Aurora Replicas, the reader endpoint load-balances each connection request among the Aurora Replicas. In that case, you can only perform read-only statements such as `SELECT` in that session. If the cluster only contains a primary instance and no Aurora Replicas, the reader endpoint connects to the primary instance. In that case, you can perform write operations through the endpoint.

The following example illustrates a reader endpoint for an Aurora MySQL DB cluster.

```
mydbcluster.cluster-ro-123456789012.us-east-1.rds.amazonaws.com:3306
```

Custom endpoint

A *custom endpoint* for an Aurora cluster represents a set of DB instances that you choose. When you connect to the endpoint, Aurora performs load balancing and chooses one of the instances in the group to handle the connection. You define which instances this endpoint refers to, and you decide what purpose the endpoint serves.

An Aurora DB cluster has no custom endpoints until you create one. You can create up to five custom endpoints for each provisioned Aurora cluster. You can't use custom endpoints for Aurora Serverless clusters.

The custom endpoint provides load-balanced database connections based on criteria other than the read-only or read/write capability of the DB instances. For example, you might define a custom endpoint to connect to instances that use a particular AWS instance class or a particular DB parameter group. Then you might tell particular groups of users about this custom endpoint. For example, you might direct internal users to low-capacity instances for report generation or ad hoc (one-time) querying, and direct production traffic to high-capacity instances.

Because the connection can go to any DB instance that is associated with the custom endpoint, we recommend that you make sure that all the DB instances within that group share some similar characteristic. Doing so ensures that the performance, memory capacity, and so on, are consistent for everyone who connects to that endpoint.

This feature is intended for advanced users with specialized kinds of workloads where it isn't practical to keep all the Aurora Replicas in the cluster identical. With custom endpoints, you can predict the capacity of the DB instance used for each connection. When you use custom endpoints, you typically don't use the reader endpoint for that cluster.

The following example illustrates a custom endpoint for a DB instance in an Aurora MySQL DB cluster.

```
myendpoint.cluster-custom-123456789012.us-east-1.rds.amazonaws.com:3306
```

Instance endpoint

An *instance endpoint* connects to a specific DB instance within an Aurora cluster. Each DB instance in a DB cluster has its own unique instance endpoint. So there is one instance endpoint for the current primary DB instance of the DB cluster, and there is one instance endpoint for each of the Aurora Replicas in the DB cluster.

The instance endpoint provides direct control over connections to the DB cluster, for scenarios where using the cluster endpoint or reader endpoint might not be appropriate. For example, your client application might require more fine-grained load balancing based on workload type. In this case, you can configure multiple clients to connect to different Aurora Replicas in a DB cluster to distribute read workloads. For an example that uses instance endpoints to improve connection speed after a failover for Aurora PostgreSQL, see [Fast failover with Amazon Aurora PostgreSQL \(p. 1423\)](#). For

an example that uses instance endpoints to improve connection speed after a failover for Aurora MySQL, see [MariaDB Connector/J failover support - case Amazon Aurora](#).

The following example illustrates an instance endpoint for a DB instance in an Aurora MySQL DB cluster.

```
mydbinstance.123456789012.us-east-1.rds.amazonaws.com:3306
```

Viewing the endpoints for an Aurora cluster

In the AWS Management Console, you see the cluster endpoint, the reader endpoint, and any custom endpoints in the detail page for each cluster. You see the instance endpoint in the detail page for each instance. When you connect, you must append the associated port number, following a colon, to the endpoint name shown on this detail page.

With the AWS CLI, you see the writer, reader, and any custom endpoints in the output of the [describe-db-clusters](#) command. For example, the following command shows the endpoint attributes for all clusters in your current AWS Region.

```
aws rds describe-db-clusters --query '*[ ].  
{Endpoint:Endpoint,ReaderEndpoint:ReaderEndpoint,CustomerEndpoints:CustomEndpoints}'
```

With the Amazon RDS API, you retrieve the endpoints by calling the [DescribeDBClusterEndpoints](#) function.

Using the cluster endpoint

Because each Aurora cluster has a single built-in cluster endpoint, whose name and other attributes are managed by Aurora, you can't create, delete, or modify this kind of endpoint.

You use the cluster endpoint when you administer your cluster, perform extract, transform, load (ETL) operations, or develop and test applications. The cluster endpoint connects to the primary instance of the cluster. The primary instance is the only DB instance where you can create tables and indexes, run `INSERT` statements, and perform other DDL and DML operations.

The physical IP address pointed to by the cluster endpoint changes when the failover mechanism promotes a new DB instance to be the read/write primary instance for the cluster. If you use any form of connection pooling or other multiplexing, be prepared to flush or reduce the time-to-live for any cached DNS information. Doing so ensures that you don't try to establish a read/write connection to a DB instance that became unavailable or is now read-only after a failover.

Using the reader endpoint

You use the reader endpoint for read-only connections for your Aurora cluster. This endpoint uses a load-balancing mechanism to help your cluster handle a query-intensive workload. The reader endpoint is the endpoint that you supply to applications that do reporting or other read-only operations on the cluster.

The reader endpoint load-balances connections to available Aurora Replicas in an Aurora DB cluster. It doesn't load-balance individual queries. If you want to load-balance each query to distribute the read workload for a DB cluster, open a new connection to the reader endpoint for each query.

Each Aurora cluster has a single built-in reader endpoint, whose name and other attributes are managed by Aurora. You can't create, delete, or modify this kind of endpoint.

If your cluster contains only a primary instance and no Aurora Replicas, the reader endpoint connects to the primary instance. In that case, you can perform write operations through this endpoint.

Tip

Through RDS Proxy, you can create additional read-only endpoints for an Aurora cluster. These endpoints perform the same kind of load-balancing as the Aurora reader endpoint. Applications can reconnect more quickly to the proxy endpoints than the Aurora reader endpoint if reader instances become unavailable. The proxy endpoints can also take advantage of other proxy features such as multiplexing. For more information, see [Using reader endpoints with Aurora clusters \(p. 316\)](#).

Using custom endpoints

You use custom endpoints to simplify connection management when your cluster contains DB instances with different capacities and configuration settings.

Previously, you might have used the CNAMES mechanism to set up Domain Name Service (DNS) aliases from your own domain to achieve similar results. By using custom endpoints, you can avoid updating CNAME records when your cluster grows or shrinks. Custom endpoints also mean that you can use encrypted Transport Layer Security/Secure Sockets Layer (TLS/SSL) connections.

Instead of using one DB instance for each specialized purpose and connecting to its instance endpoint, you can have multiple groups of specialized DB instances. In this case, each group has its own custom endpoint. This way, Aurora can perform load balancing among all the instances dedicated to tasks such as reporting or handling production or internal queries. The custom endpoints provide load balancing and high availability for each group of DB instances within your cluster. If one of the DB instances within a group becomes unavailable, Aurora directs subsequent custom endpoint connections to one of the other DB instances associated with the same endpoint.

Topics

- [Specifying properties for custom endpoints \(p. 36\)](#)
- [Membership rules for custom endpoints \(p. 37\)](#)
- [Managing custom endpoints \(p. 37\)](#)

Specifying properties for custom endpoints

The maximum length for a custom endpoint name is 63 characters. You can see the name format following:

`endpointName.cluster-custom-customerDnsIdentifier.dnsSuffix`

Because custom endpoint names don't include the name of your cluster, you don't have to change those names if you rename a cluster. You can't reuse the same custom endpoint name for more than one cluster in the same region. Give each custom endpoint a name that is unique across the clusters owned by your user ID within a particular region.

Each custom endpoint has an associated type that determines which DB instances are eligible to be associated with that endpoint. Currently, the type can be READER, WRITER, or ANY. The following considerations apply to the custom endpoint types:

- Only DB instances that are read-only Aurora Replicas can be part of a READER custom endpoint. The READER type applies only to clusters using single-master replication, because those clusters can include multiple read-only DB instances.
- Both read-only Aurora Replicas and the read/write primary instance can be part of an ANY custom endpoint. Aurora directs connections to cluster endpoints with type ANY to any associated DB instance with equal probability. Because you can't determine in advance if you are connecting to the primary instance of a read-only Aurora Replica, use this kind of endpoint for read-only connections only. The ANY type applies to clusters using any replication topology.

- The `WRITER` type applies only to multi-master clusters, because those clusters can include multiple read/write DB instances.
- If you try to create a custom endpoint with a type that isn't appropriate based on the replication configuration for a cluster, Aurora returns an error.

Membership rules for custom endpoints

When you add a DB instance to a custom endpoint or remove it from a custom endpoint, any existing connections to that DB instance remain active.

You can define a list of DB instances to include in, or exclude from, a custom endpoint. We refer to these lists as *static* and *exclusion* lists, respectively. You can use the inclusion/exclusion mechanism to further subdivide the groups of DB instances, and to make sure that the set of custom endpoints covers all the DB instances in the cluster. Each custom endpoint can contain only one of these list types.

In the AWS Management Console, the choice is represented by the check box **Attach future instances added to this cluster**. When you keep check box clear, the custom endpoint uses a static list containing only the DB instances specified in the dialog. When you choose the check box, the custom endpoint uses an exclusion list. In this case, the custom endpoint represents all DB instances in the cluster (including any that you add in the future) except the ones left unselected in the dialog. The AWS CLI and Amazon RDS API have parameters representing each kind of list. When you use the AWS CLI or Amazon RDS API, you can't add or remove individual members to the lists; you always specify the entire new list.

Aurora doesn't change the DB instances specified in the static or exclusion lists when DB instances change roles between primary instance and Aurora Replica due to failover or promotion. For example, a custom endpoint with type `READER` might include a DB instance that was an Aurora Replica and then was promoted to a primary instance. The type of a custom endpoint (`READER`, `WRITER`, or `ANY`) determines what kinds of operations you can perform through that endpoint.

You can associate a DB instance with more than one custom endpoint. For example, suppose that you add a new DB instance to a cluster, or that Aurora adds a DB instance automatically through the autoscaling mechanism. In these cases, the DB instance is added to all custom endpoints for which it is eligible. Which endpoints the DB instance is added to is based on the custom endpoint type of `READER`, `WRITER`, or `ANY`, plus any static or exclusion lists defined for each endpoint. For example, if the endpoint includes a static list of DB instances, newly added Aurora Replicas aren't added to that endpoint. Conversely, if the endpoint has an exclusion list, newly added Aurora Replicas are added to the endpoint, if they aren't named in the exclusion list and their roles match the type of the custom endpoint.

If an Aurora Replica becomes unavailable, it remains associated with any custom endpoints. For example, it remains part of the custom endpoint when it is unhealthy, stopped, rebooting, and so on. However, you can't connect to it through those endpoints until it becomes available again.

Managing custom endpoints

Because newly created Aurora clusters have no custom endpoints, you must create and manage these objects yourself. You do so using the AWS Management Console, AWS CLI, or Amazon RDS API.

Note

You must also create and manage custom endpoints for Aurora clusters restored from snapshots. Custom endpoints are not included in the snapshot. You create them again after restoring, and choose new endpoint names if the restored cluster is in the same region as the original one.

To work with custom endpoints from the AWS Management Console, you navigate to the details page for your Aurora cluster and use the controls under the **Custom Endpoints** section.

To work with custom endpoints from the AWS CLI, you can use these operations:

- [create-db-cluster-endpoint](#)
- [describe-db-cluster-endpoints](#)
- [modify-db-cluster-endpoint](#)
- [delete-db-cluster-endpoint](#)

To work with custom endpoints through the Amazon RDS API, you can use the following functions:

- [CreateDBClusterEndpoint](#)
- [DescribeDBClusterEndpoints](#)
- [ModifyDBClusterEndpoint](#)
- [DeleteDBClusterEndpoint](#)

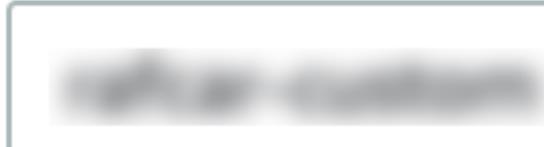

Creating a custom endpoint

Console

To create a custom endpoint with the AWS Management Console, go to the cluster detail page and choose the `Create custom endpoint` action in the **Endpoints** section. Choose a name for the custom endpoint, unique for your user ID and region. To choose a list of DB instances that remains the same even as the cluster expands, keep the check box **Attach future instances added to this cluster** clear. When you choose that check box, the custom endpoint dynamically adds any new instances as you add them to the cluster.

Create custom e

Endpoint name

Endpoint name is case insensitive,
First character must be a letter. Ca

Endpoint members

Filter database

You can't select the custom endpoint type of **ANY** or **READER** in the AWS Management Console. All the custom endpoints you create through the AWS Management Console have a type of **ANY**.

AWS CLI

To create a custom endpoint with the AWS CLI, run the [create-db-cluster-endpoint](#) command.

The following command creates a custom endpoint attached to a specific cluster. Initially, the endpoint is associated with all the Aurora Replica instances in the cluster. A subsequent command associates it with a specific set of DB instances in the cluster.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample \
--endpoint-type reader \
--db-cluster-identifier cluster_id

aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample \
--static-members instance_name_1 instance_name_2
```

For Windows:

```
aws rds create-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample ^
--endpoint-type reader ^
--db-cluster-identifier cluster_id

aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample ^
--static-members instance_name_1 instance_name_2
```

RDS API

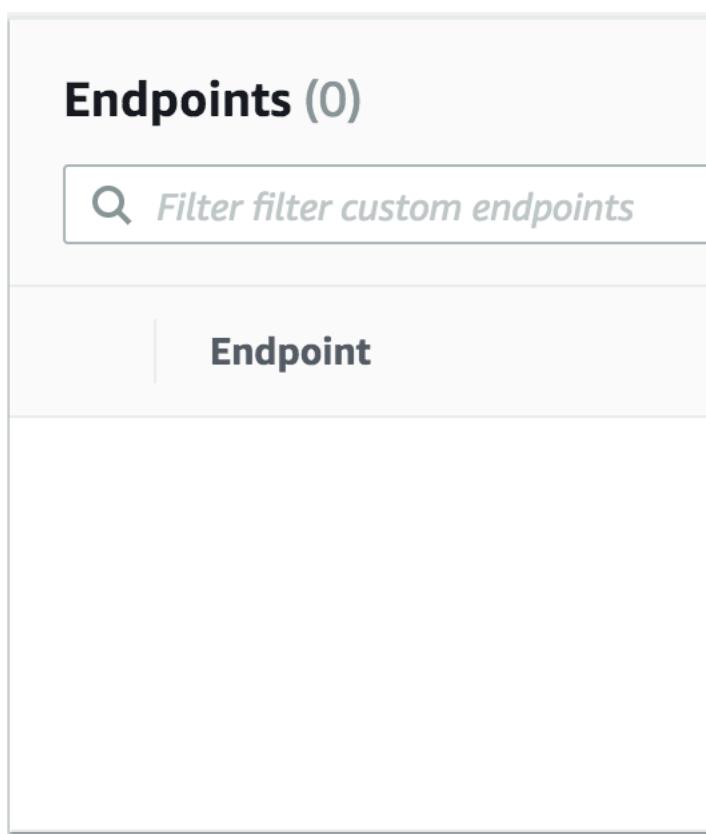

To create a custom endpoint with the RDS API, run the [CreateDBClusterEndpoint](#) operation.

Viewing custom endpoints

Console

To view custom endpoints with the AWS Management Console, go to the cluster detail page for the cluster and look under the **Endpoints** section. This section contains information only about custom endpoints. The details for the built-in endpoints are listed in the main **Details** section. To see the details for a specific custom endpoint, select its name to bring up the detail page for that endpoint.

The following screenshot shows how the list of custom endpoints for an Aurora cluster is initially empty.

After you create some custom endpoints for that cluster, they are shown under the **Endpoints** section.

Endpoints (2)

Filter filter custom endpoints

Filter endpoint members

To see the additional detail of whether new DB instances added to the cluster are automatically added to the endpoint also, bring up the **Edit** dialog for the endpoint.

AWS CLI

To view custom endpoints with the AWS CLI, run the [describe-db-cluster-endpoints](#) command.

The following command shows the custom endpoints associated with a specified cluster in a specified region. The output includes both the built-in endpoints and any custom endpoints.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-endpoints --region region_name \  
--db-cluster-identifier cluster_id
```

For Windows:

```
aws rds describe-db-cluster-endpoints --region region_name ^  
--db-cluster-identifier cluster_id
```

The following shows some sample output from a `describe-db-cluster-endpoints` command. The `EndpointType` of WRITER or READER denotes the built-in read/write and read-only endpoints for the cluster. The `EndpointType` of CUSTOM denotes endpoints that you create and choose the associated DB instances. One of the endpoints has a non-empty `StaticMembers` field, denoting that it is associated with a precise set of DB instances. The other endpoint has a non-empty `ExcludedMembers` field, denoting that the endpoint is associated with all DB instances *other than* the ones listed under `ExcludedMembers`. This second kind of custom endpoint grows to accommodate new instances as you add them to the cluster.

```
{  
  "DBClusterEndpoints": [  
    {  
      "Endpoint": "custom-endpoint-demo.cluster-123456789012.ca-central-1.rds.amazonaws.com",

```

RDS API

To view custom endpoints with the RDS API, run the [DescribeDBClusterEndpoints.html](#) operation.

Editing a custom endpoint

You can edit the properties of a custom endpoint to change which DB instances are associated with the endpoint. You can also change an endpoint between a static list and an exclusion list. If you need more details about these endpoint properties, see [Membership rules for custom endpoints \(p. 37\)](#).

You can't connect to or use a custom endpoint while the changes from an edit action are in progress. It might take some minutes before the endpoint status returns to **Available** and you can connect again.

Console

To edit a custom endpoint with the AWS Management Console, you can select the endpoint on the cluster detail page, or bring up the detail page for the endpoint, and choose the **Edit** action.

RDS > Clusters: [REDACTED]

Edit endpoint:

Endpoint members

Filter database

- | DB instance name

<input checked="" type="checkbox"/>	[REDACTED]
<input checked="" type="checkbox"/>	[REDACTED]

AWS CLI

To edit a custom endpoint with the AWS CLI, run the [modify-db-cluster-endpoint](#) command.

The following commands change the set of DB instances that apply to a custom endpoint and optionally switches between the behavior of a static or exclusion list. The `--static-members` and `--excluded-members` parameters take a space-separated list of DB instance identifiers.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint \
--static-members db-instance-id-1 db-instance-id-2 db-instance-id-3 \
--region region_name

aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint \
--excluded-members db-instance-id-4 db-instance-id-5 \
--region region_name
```

For Windows:

```
aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint ^
--static-members db-instance-id-1 db-instance-id-2 db-instance-id-3 ^
--region region_name

aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint ^
--excluded-members db-instance-id-4 db-instance-id-5 ^
--region region_name
```

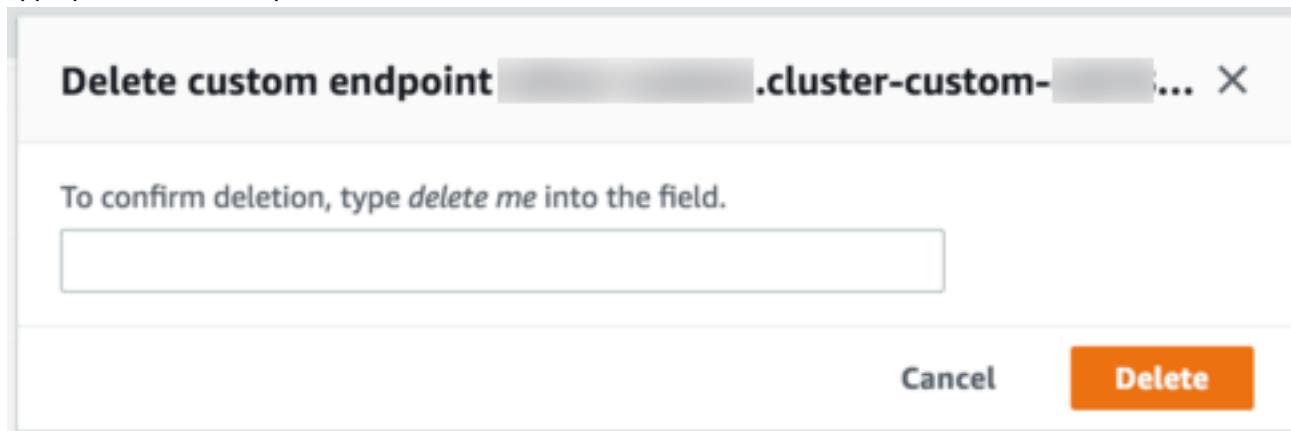

RDS API

To edit a custom endpoint with the RDS API, run the [ModifyDBClusterEndpoint.html](#) operation.

Deleting a custom endpoint

Console

To delete a custom endpoint with the AWS Management Console, go to the cluster detail page, select the appropriate custom endpoint, and select the **Delete** action.

AWS CLI

To delete a custom endpoint with the AWS CLI, run the [delete-db-cluster-endpoint](#) command.

The following command deletes a custom endpoint. You don't need to specify the associated cluster, but you must specify the region.

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster-endpoint --db-cluster-endpoint-identifier custom-end-point-id \  
--region region_name
```

For Windows:

```
aws rds delete-db-cluster-endpoint --db-cluster-endpoint-identifier custom-end-point-id ^  
--region region_name
```

RDS API

To delete a custom endpoint with the RDS API, run the [DeleteDBClusterEndpoint](#) operation.

End-to-end AWS CLI example for custom endpoints

The following tutorial uses AWS CLI examples with Unix shell syntax to show you might define a cluster with several "small" DB instances and a few "big" DB instances, and create custom endpoints to connect to each set of DB instances. To run similar commands on your own system, you should be familiar enough with the basics of working with Aurora clusters and AWS CLI usage to supply your own values for parameters such as region, subnet group, and VPC security group.

This example demonstrates the initial setup steps: creating an Aurora cluster and adding DB instances to it. This is a heterogeneous cluster, meaning not all the DB instances have the same capacity. Most instances use the AWS instance class db.r4.4xlarge, but the last two DB instances use db.r4.16xlarge. Each of these sample `create-db-instance` commands prints its output to the screen and saves a copy of the JSON in a file for later inspection.

```
aws rds create-db-cluster --db-cluster-identifier custom-endpoint-demo --engine aurora \  
--engine-version 5.6.10a --master-username $MASTER_USER --master-user-password  
$MASTER_PW \  
--db-subnet-group-name $SUBNET_GROUP --vpc-security-group-ids $VPC_SECURITY_GROUP \  
--region $REGION  
  
for i in 01 02 03 04 05 06 07 08  
do  
    aws rds create-db-instance --db-instance-identifier custom-endpoint-demo-${i} \  
    --engine aurora --db-cluster-identifier custom-endpoint-demo --db-instance-class  
db.r4.4xlarge \  
    --region $REGION \  
    | tee custom-endpoint-demo-${i}.json  
done  
  
for i in 09 10  
do  
    aws rds create-db-instance --db-instance-identifier custom-endpoint-demo-${i} \  
    --engine aurora --db-cluster-identifier custom-endpoint-demo --db-instance-class  
db.r4.16xlarge \  
    --region $REGION \  
    | tee custom-endpoint-demo-${i}.json  
done
```

The larger instances are reserved for specialized kinds of reporting queries. To make it unlikely for them to be promoted to the primary instance, the following example changes their promotion tier to the lowest priority.

```
for i in 09 10
do
    aws rds modify-db-instance --db-instance-identifier custom-endpoint-demo-${i} \
        --region $REGION --promotion-tier 15
done
```

Suppose that you want to use the two "bigger" instances only for the most resource-intensive queries. To do this, you can first create a custom read-only endpoint. Then you can add a static list of members so that the endpoint connects only to those DB instances. Those instances are already in the lowest promotion tier, making it unlikely either of them will be promoted to the primary instance. If one of them is promoted to the primary instance, it becomes unreachable through this endpoint because we specified the `READER` type instead of the `ANY` type.

The following example demonstrates the create and modify endpoint commands, and sample JSON output showing the initial and modified state of the custom endpoint.

```
$ aws rds create-db-cluster-endpoint --region $REGION \
    --db-cluster-identifier custom-endpoint-demo \
    --db-cluster-endpoint-identifier big-instances --endpoint-type reader
{
    "EndpointType": "CUSTOM",
    "Endpoint": "big-instances.cluster-custom-123456789012.ca-central-1.rds.amazonaws.com",
    "DBClusterEndpointIdentifier": "big-instances",
    "DBClusterIdentifier": "custom-endpoint-demo",
    "StaticMembers": [],
    "DBClusterEndpointResourceIdentifier": "cluster-endpoint-W7PE3TLLFNSHXQKFU6J6NV5FHU",
    "ExcludedMembers": [],
    "CustomEndpointType": "READER",
    "Status": "creating",
    "DBClusterEndpointArn": "arn:aws:rds:ca-central-1:111122223333:cluster-endpoint:big-
instances"
}

$ aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier big-instances \
    --static-members custom-endpoint-demo-09 custom-endpoint-demo-10 --region $REGION
{
    "EndpointType": "CUSTOM",
    "ExcludedMembers": [],
    "DBClusterEndpointIdentifier": "big-instances",
    "DBClusterEndpointResourceIdentifier": "cluster-endpoint-W7PE3TLLFNSHXQKFU6J6NV5FHU",
    "CustomEndpointType": "READER",
    "DBClusterEndpointArn": "arn:aws:rds:ca-central-1:111122223333:cluster-endpoint:big-
instances",
    "StaticMembers": [
        "custom-endpoint-demo-10",
        "custom-endpoint-demo-09"
    ],
    "Status": "modifying",
    "Endpoint": "big-instances.cluster-custom-123456789012.ca-central-1.rds.amazonaws.com",
    "DBClusterIdentifier": "custom-endpoint-demo"
}
```

The default `READER` endpoint for the cluster can connect to either the "small" or "big" DB instances, making it impractical to predict query performance and scalability when the cluster becomes busy. To divide the workload cleanly between the sets of DB instances, you can ignore the default `READER` endpoint and create a second custom endpoint that connects to all other DB instances. The following example does so by creating a custom endpoint and then adding an exclusion list. Any other DB instances you add to the cluster later will be added to this endpoint automatically. The `ANY` type means that this endpoint is associated with eight instances in total: the primary instance and another seven Aurora Replicas. If the example used the `READER` type, the custom endpoint would only be associated with the seven Aurora Replicas.

```
$ aws rds create-db-cluster-endpoint --region $REGION --db-cluster-identifier custom-endpoint-demo \
    --db-cluster-endpoint-identifier small-instances --endpoint-type any
{
    "Status": "creating",
    "DBClusterEndpointIdentifier": "small-instances",
    "CustomEndpointType": "ANY",
    "EndpointType": "CUSTOM",
    "Endpoint": "small-instances.cluster-custom-123456789012.ca-central-1.rds.amazonaws.com",
    "StaticMembers": [],
    "ExcludedMembers": [],
    "DBClusterIdentifier": "custom-endpoint-demo",
    "DBClusterEndpointArn": "arn:aws:rds:ca-central-1:111122223333:cluster-endpoint:small-instances",
    "DBClusterEndpointResourceIdentifier": "cluster-endpoint-6RDDXQOC3AKKZT2PRD7ST37BMY"
}

$ aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier small-instances \
    --excluded-members custom-endpoint-demo-09 custom-endpoint-demo-10 --region $REGION
{
    "DBClusterEndpointIdentifier": "small-instances",
    "DBClusterEndpointArn": "arn:aws:rds:ca-central-1:111122223333:cluster-endpoint:small-instances",
    "DBClusterEndpointResourceIdentifier": "cluster-endpoint-6RDDXQOC3AKKZT2PRD7ST37BMY",
    "CustomEndpointType": "ANY",
    "Endpoint": "small-instances.cluster-custom-123456789012.ca-central-1.rds.amazonaws.com",
    "EndpointType": "CUSTOM",
    "ExcludedMembers": [
        "custom-endpoint-demo-09",
        "custom-endpoint-demo-10"
    ],
    "StaticMembers": [],
    "DBClusterIdentifier": "custom-endpoint-demo",
    "Status": "modifying"
}
```

The following example checks the state of the endpoints for this cluster. The cluster still has its original cluster endpoint, with `EndPointType` of `WRITER`, which you would still use for administration, ETL, and other write operations. It still has its original `READER` endpoint, which you wouldn't use because each connection to it might be directed to a "small" or "big" DB instance. The custom endpoints make this behavior predictable, with connections guaranteed to use one of the "small" or "big" DB instances based on the endpoint you specify.

```
$ aws rds describe-db-cluster-endpoints --region $REGION
{
    "DBClusterEndpoints": [
        {
            "EndpointType": "WRITER",
            "Endpoint": "custom-endpoint-demo.cluster-123456789012.ca-central-1.rds.amazonaws.com",
            "Status": "available",
            "DBClusterIdentifier": "custom-endpoint-demo"
        },
        {
            "EndpointType": "READER",
            "Endpoint": "custom-endpoint-demo.cluster-ro-123456789012.ca-central-1.rds.amazonaws.com",
            "Status": "available",
            "DBClusterIdentifier": "custom-endpoint-demo"
        }
    ]
}
```

```

        "Endpoint": "small-instances.cluster-custom-123456789012.ca-
central-1.rds.amazonaws.com",
        "CustomEndpointType": "ANY",
        "DBClusterEndpointArn": "arn:aws:rds:ca-central-1:111122223333:cluster-
endpoint:small-instances",
        "ExcludedMembers": [
            "custom-endpoint-demo-09",
            "custom-endpoint-demo-10"
        ],
        "DBClusterEndpointResourceIdentifier": "cluster-
endpoint-6RDDXQOC3AKKZT2PRD7ST37BMY",
        "DBClusterIdentifier": "custom-endpoint-demo",
        "StaticMembers": [],
        "EndpointType": "CUSTOM",
        "DBClusterEndpointIdentifier": "small-instances",
        "Status": "modifying"
    },
    {
        "Endpoint": "big-instances.cluster-custom-123456789012.ca-
central-1.rds.amazonaws.com",
        "CustomEndpointType": "READER",
        "DBClusterEndpointArn": "arn:aws:rds:ca-central-1:111122223333:cluster-
endpoint:big-instances",
        "ExcludedMembers": [],
        "DBClusterEndpointResourceIdentifier": "cluster-endpoint-
W7PE3TLLFNSHXQKFU6J6NV5FHU",
        "DBClusterIdentifier": "custom-endpoint-demo",
        "StaticMembers": [
            "custom-endpoint-demo-10",
            "custom-endpoint-demo-09"
        ],
        "EndpointType": "CUSTOM",
        "DBClusterEndpointIdentifier": "big-instances",
        "Status": "available"
    }
]
}

```

The final examples demonstrate how successive database connections to the custom endpoints connect to the various DB instances in the Aurora cluster. The `small-instances` endpoint always connects to the `db.r4.4xlarge` DB instances, which are the lower-numbered hosts in this cluster.

```

$ mysql -h small-instances.cluster-custom-123456789012.ca-central-1.rds.amazonaws.com -u
$MYUSER -p
mysql> select @@aurora_server_id;

Using the instance endpoints

Each DB instance in an Aurora cluster has its own built-in instance endpoint, whose name and other attributes are managed by Aurora. You can't create, delete, or modify this kind of endpoint. You might be familiar with instance endpoints if you use Amazon RDS. However, with Aurora you typically use the writer and reader endpoints more often than the instance endpoints.

In day-to-day Aurora operations, the main way that you use instance endpoints is to diagnose capacity or performance issues that affect one specific instance in an Aurora cluster. While connected to a specific instance, you can examine its status variables, metrics, and so on. Doing this can help you determine what's happening for that instance that's different from what's happening for other instances in the cluster.

In advanced use cases, you might configure some DB instances differently than others. In this case, use the instance endpoint to connect directly to an instance that is smaller, larger, or otherwise has different characteristics than the others. Also, set up failover priority so that this special DB instance is the last choice to take over as the primary instance. We recommend that you use custom endpoints instead of the instance endpoint in such cases. Doing so simplifies connection management and high availability as you add more DB instances to your cluster.

How Aurora endpoints work with high availability

For clusters where high availability is important, use the writer endpoint for read/write or general-purpose connections and the reader endpoint for read-only connections. The writer and reader endpoints manage DB instance failover better than instance endpoints do. Unlike the instance endpoints, the writer and reader endpoints automatically change which DB instance they connect to if a DB instance in your cluster becomes unavailable.

If the primary DB instance of a DB cluster fails, Aurora automatically fails over to a new primary DB instance. It does so by either promoting an existing Aurora Replica to a new primary DB instance or creating a new primary DB instance. If a failover occurs, you can use the writer endpoint to reconnect to the newly promoted or created primary DB instance, or use the reader endpoint to reconnect to one of

the Aurora Replicas in the DB cluster. During a failover, the reader endpoint might direct connections to the new primary DB instance of a DB cluster for a short time after an Aurora Replica is promoted to the new primary DB instance.

If you design your own application logic to manage connections to instance endpoints, you can manually or programmatically discover the resulting set of available DB instances in the DB cluster. You can then confirm their instance classes after failover and connect to an appropriate instance endpoint.

For more information about failovers, see [Fault tolerance for an Aurora DB cluster \(p. 69\)](#).

Aurora DB instance classes

The DB instance class determines the computation and memory capacity of an Aurora DB instance. The DB instance class you need depends on your processing power and memory requirements.

For more information about instance class pricing, see [Amazon RDS pricing](#).

Topics

- [DB instance class types \(p. 54\)](#)
- [Supported DB engines for DB instance classes \(p. 54\)](#)
- [Determining DB instance class support in AWS Regions \(p. 59\)](#)
- [Hardware specifications for DB instance classes for Aurora \(p. 62\)](#)

DB instance class types

Amazon Aurora supports two types of instance classes: memory optimized and burstable performance. For more information about Amazon EC2 instance types, see [Instance types](#) in the Amazon EC2 documentation.

The following are the memory optimized DB instance classes available:

- **db.x2g** – Instance classes optimized for memory-intensive applications and powered by AWS Graviton2 processors. These offer low cost per GiB of memory.
- **db.r6g** – Instance classes powered by AWS Graviton2 processors. These are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL.
- **db.r5** – Latest generation instance classes optimized for memory-intensive applications. These offer improved networking performance. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.r3** – Instance classes that provide memory optimization.

The following are the burstable performance DB instance classes available:

- **db.t4g** – Newest-generation burstable instance classes powered by Arm-based AWS Graviton2 processors. These deliver better price performance than previous-generation burstable performance DB instance classes for a broad set of burstable workloads. T4g instances are configured for Unlimited mode, which means that they can burst beyond the baseline over a 24-hour window for an additional charge. We recommend using these instance classes only for development and test servers, or other nonproduction servers.
- **db.t3** – Next generation instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. T3 instances are configured for Unlimited mode. These instance classes provide more computing capacity than the previous db.t2 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor. We recommend using these instance classes only for development and test servers, or other nonproduction servers.
- **db.t2** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. T2 instances can be configured for Unlimited mode. We recommend using these instance classes only for development and test servers, or other nonproduction servers.

For DB instance class hardware specifications, see [Hardware specifications for DB instance classes for Aurora \(p. 62\)](#).

Supported DB engines for DB instance classes

The following are DB engine considerations for DB instance classes:

- **Aurora support for db.x2g**

- Aurora MySQL versions 2.09.2 and higher, 2.10.0 and higher, and 3.01.0 and higher support the db.x2g instance classes.
- Aurora PostgreSQL versions 11.9 and higher, 12.4 and higher, and 13.3 and higher support the db.x2g instance classes.

- **Aurora support for db.r6g**

- Aurora MySQL versions 2.09.2 and higher and 2.10.0 and higher support the db.r6g instance classes.
- Aurora PostgreSQL versions 13.3, 12.4 and higher and versions 11.9 and higher support the db.r6g instance classes.

- **Aurora support for db.t4g**

- Aurora MySQL versions 2.09.2 and higher, 2.10.0 and higher, and 3.01.0 and higher support the db.t4g instance classes, specifically db.t4g.large and db.t4g.medium.
- Aurora PostgreSQL versions 11.9 and higher, 12.4 and higher, and 13.3 and higher support the db.t4g instance classes, specifically db.t4g.large and db.t4g.medium.

- **Aurora support for db.t3**

- Aurora MySQL supports the db.t3.medium and db.t3.small instance classes for version 1.15 and higher, and all 2.x versions. Aurora MySQL supports the db.t3.large class in version 2.10 and higher.
- Aurora MySQL version 3 includes some changes to instance class support.
 - With Aurora MySQL version 3, you can't use db.r3, db.r4, or db.t2 instance classes.
 - With Aurora MySQL version 3, you can't use the db.t3.small instance class.

The smallest instance classes that you can use with version 3 are t3.medium and t4g.medium.

- For Aurora MySQL db.r5, db.r4, and db.t3 DB instance classes, no instances in the cluster can have pending instance-level system updates. To see pending system updates, use the following AWS Command Line Interface (AWS CLI) command.

```
aws rds describe-pending-maintenance-actions
```

- Aurora PostgreSQL version 13.3 supports db.t3 instance classes.

In the following table, you can find details about supported Amazon Aurora DB instance classes for the Aurora DB engines.

Instance class	Aurora MySQL	Aurora PostgreSQL
db.x2g – memory optimized instance classes powered by AWS Graviton2 processors		
db.x2g.16xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.x2g.12xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.x2g.8xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher

Instance class	Aurora MySQL	Aurora PostgreSQL
db.x2g.4xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.x2g.2xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.x2g.xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.x2g.large	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.r6g – Memory-optimized instance classes powered by AWS Graviton2 processors		
db.r6g.16xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.r6g.12xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.r6g.8xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.r6g.4xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.r6g.2xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.r6g.xlarge	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.r6g.large	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.r5 – latest generation memory optimized instance classes		
db.r5.24xlarge	1.22 and higher, 2.06 and higher, 3.01.0 and higher	Yes
db.r5.16xlarge	1.22 and higher, 2.06 and higher, 3.01.0 and higher	Yes
db.r5.12xlarge	1.14.4 and higher, 3.01.0 and higher	Yes

Instance class	Aurora MySQL	Aurora PostgreSQL
db.r5.8xlarge	1.22 and higher, 2.06 and higher, 3.01.0 and higher	Yes
db.r5.4xlarge	1.14.4 and higher, 3.01.0 and higher	Yes
db.r5.2xlarge	1.14.4 and higher, 3.01.0 and higher	Yes
db.r5.xlarge	1.14.4 and higher, 3.01.0 and higher	Yes
db.r5.large	1.14.4 and higher, 3.01.0 and higher	Yes
db.r4 – memory optimized instance classes		
db.r4.16xlarge	1.14.4 and higher; not supported in 3.01.0 and higher	12.4 and higher, 11.4 and higher, 10.4 and higher, and 9.6.3 and higher
db.r4.8xlarge	1.14.4 and higher; not supported in 3.01.0 and higher	12.4 and higher, 11.4 and higher, 10.4 and higher, and 9.6.3 and higher
db.r4.4xlarge	1.14.4 and higher; not supported in 3.01.0 and higher	12.4 and higher, 11.4 and higher, 10.4 and higher, and 9.6.3 and higher
db.r4.2xlarge	1.14.4 and higher; not supported in 3.01.0 and higher	12.4 and higher, 11.4 and higher, 10.4 and higher, and 9.6.3 and higher
db.r4.xlarge	1.14.4 and higher; not supported in 3.01.0 and higher	12.4 and higher, 11.4 and higher, 10.4 and higher, and 9.6.3 and higher
db.r4.large	1.14.4 and higher; not supported in 3.01.0 and higher	12.4 and higher, 11.4 and higher, 10.4 and higher, and 9.6.3 and higher
db.r3 – memory optimized instance classes		
db.r3.8xlarge	All 1.x and 2.x versions; not supported in 3.01.0 and higher	No
db.r3.4xlarge	All 1.x and 2.x versions; not supported in 3.01.0 and higher	No

Instance class	Aurora MySQL	Aurora PostgreSQL
db.r3.2xlarge	All 1.x and 2.x versions; not supported in 3.01.0 and higher	No
db.r3.xlarge	All 1.x and 2.x versions; not supported in 3.01.0 and higher	No
db.r3.large	All 1.x and 2.x versions; not supported in 3.01.0 and higher	No
db.t4g – newest generation burstable performance instance classes powered by AWS Graviton2 processors		
db.t4g.2xlarge	No	No
db.t4g.xlarge	No	No
db.t4g.large	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.t4g.medium	2.09.2 and higher, 2.10.0 and higher, 3.01.0 and higher	13.3, 12.4 and higher, 11.9 and higher
db.t4g.small	No	No
db.t3 – Next generation burstable performance instance classes		
db.t3.2xlarge	No	No
db.t3.xlarge	No	No
db.t3.large	2.10 and higher, 3.01.0 and higher	13.3, 11.6 and higher, 10.11 and higher
db.t3.medium	1.14.4 and higher, 3.01.0 and higher	13.3, 10.11 and higher
db.t3.small	1.14.4 and higher; not supported in 3.01.0 and higher	No
db.t3.micro	No	No
db.t2 – burstable performance instance classes		
db.t2.medium	All 1.x and 2.x versions; not supported in 3.01.0 and higher	No
db.t2.small	All 1.x and 2.x versions; not supported in 3.01.0 and higher	No

Determining DB instance class support in AWS Regions

To determine the DB instance classes supported by each DB engine in a specific AWS Region, you can use the AWS Management Console, the [Amazon RDS Pricing](#) page, or the `describe-orderable-db-instance-options` AWS CLI command.

Note

When you perform operations with the AWS CLI, such as creating or modifying a DB cluster, it automatically shows the supported DB instance classes for a specific DB engine, DB engine version, and AWS Region.

Contents

- [Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions \(p. 59\)](#)
- [Using the AWS CLI to determine DB instance class support in AWS Regions \(p. 59\)](#)
 - [Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region \(p. 60\)](#)
 - [Listing the DB engine versions that support a specific DB instance class in an AWS Region \(p. 61\)](#)

Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions

You can use the [Amazon RDS Pricing](#) page to determine the DB instance classes supported by each DB engine in a specific AWS Region.

To use the pricing page to determine the DB instance classes supported by each engine in a Region

1. Go to [Amazon RDS Pricing](#).
2. Choose **Amazon Aurora**.
3. In **DB Instances**, open **MySQL-Compatible Edition** or **PostgreSQL-Compatible Edition**.
4. To see the DB instance classes available in an AWS Region, choose the AWS Region in **Region** in the appropriate subsection.

Using the AWS CLI to determine DB instance class support in AWS Regions

You can use the AWS CLI to determine which DB instance classes are supported for specific DB engines and DB engine versions in an AWS Region.

To use the AWS CLI examples in this section, make sure that you enter valid values for the DB engine, DB engine version, DB instance class, and AWS Region. The following table shows the valid DB engine values.

Engine name	Engine value in CLI commands	More information about versions
MySQL 5.6-compatible Aurora	aurora	Database engine updates for Amazon Aurora MySQL version 1 (p. 1196)

Engine name	Engine value in CLI commands	More information about versions
MySQL 5.7-compatible and 8.0-compatible Aurora	aurora-mysql	Database engine updates for Amazon Aurora MySQL version 2 (p. 1108) , Database engine updates for Amazon Aurora MySQL version 3 (p. 1108)
Aurora PostgreSQL	aurora-postgresql	Amazon Aurora PostgreSQL releases and engine versions (p. 1599)

For information about AWS Region names, see [AWS Regions \(p. 11\)](#).

The following examples demonstrate how to determine DB instance class support in an AWS Region using the [describe-orderable-db-instance-options](#) AWS CLI command.

Topics

- [Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region \(p. 60\)](#)
- [Listing the DB engine versions that support a specific DB instance class in an AWS Region \(p. 61\)](#)

[Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region](#)

To list the DB instance classes that are supported by a specific DB engine version in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --engine-version version \
  --query "OrderableDBInstanceOptions[].
{DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0]}" \
  --output table \
  --region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --engine-version version ^
  --query "OrderableDBInstanceOptions[].
{DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0]}" ^
  --output table ^
  --region region
```

The output also shows the engine modes that are supported for each DB instance class.

For example, the following command lists the supported DB instance classes for version 12.4 of the Aurora PostgreSQL DB engine in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --engine-version
  12.4 \
  --query "OrderableDBInstanceOptions[].
{DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0]}" \
  --output table \
```

```
--region us-east-1
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --engine-version 12.4 ^
--query "OrderableDBInstanceOptions[].
{DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0]}" ^
--output table ^
--region us-east-1
```

[Listing the DB engine versions that support a specific DB instance class in an AWS Region](#)

To list the DB engine versions that support a specific DB instance class in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-class DB_instance_class \
--query "OrderableDBInstanceOptions[].
{EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}" \
--output table \
--region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-class DB_instance_class ^
--query "OrderableDBInstanceOptions[].
{EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}" ^
--output table ^
--region region
```

The output also shows the engine modes that are supported for each DB engine version.

For example, the following command lists the DB engine versions of the Aurora PostgreSQL DB engine that support the db.r5.large DB instance class in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --db-instance-class db.r5.large \
--query "OrderableDBInstanceOptions[].
{EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}" \
--output table \
--region us-east-1
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --db-instance-class db.r5.large ^
--query "OrderableDBInstanceOptions[].
{EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}" ^
--output table ^
--region us-east-1
```

Hardware specifications for DB instance classes for Aurora

The following terminology is used to describe hardware specifications for DB instance classes:

vCPU

The number of virtual central processing units (CPUs). A *virtual CPU* is a unit of capacity that you can use to compare DB instance classes. Instead of purchasing or leasing a particular processor to use for several months or years, you are renting capacity by the hour. Our goal is to make a consistent and specific amount of CPU capacity available, within the limits of the actual underlying hardware.

ECU

The relative measure of the integer processing power of an Amazon EC2 instance. To make it easy for developers to compare CPU capacity between different instance classes, we have defined an Amazon EC2 Compute Unit. The amount of CPU that is allocated to a particular instance is expressed in terms of these EC2 Compute Units. One ECU currently provides CPU capacity equivalent to a 1.0–1.2 GHz 2007 Opteron or 2007 Xeon processor.

Memory (GiB)

The RAM, in gibibytes, allocated to the DB instance. There is often a consistent ratio between memory and vCPU. As an example, take the db.r4 instance class, which has a memory to vCPU ratio similar to the db.r5 instance class. However, for most use cases the db.r5 instance class provides better, more consistent performance than the db.r4 instance class.

Max. Bandwidth (Mbps)

The maximum bandwidth in megabits per second. Divide by 8 to get the expected throughput in megabytes per second.

Note

This figure refers to I/O bandwidth for local storage within the DB instance. It doesn't apply to communication with the Aurora cluster volume.

Network Performance

The network speed relative to other DB instance classes.

In the following table, you can find hardware details about the Amazon RDS DB instance classes for Aurora.

For information about Aurora DB engine support for each DB instance class, see [Supported DB engines for DB instance classes \(p. 54\)](#).

Instance class	vCPU	ECU	Memory (GiB)	Max. bandwidth (mbps) of local storage	Network performance
db.x2g – memory-optimized instance classes					
db.x2g.16xlarge	64	—	1024	19,000	25 Gbps
db.x2g.12xlarge	48	—	768	14,250	20 Gbps
db.x2g.8xlarge	32	—	512	9,500	12 Gbps
db.x2g.4xlarge	16	—	256	4,750	Up to 10 Gbps
db.x2g.2xlarge	8	—	128	Up to 4,750	Up to 10 Gbps

Instance class	vCPU	ECU	Memory (GiB)	Max. bandwidth (mbps) of local storage	Network performance
db.x2g.xlarge	4	—	64	Up to 4,750	Up to 10 Gbps
db.x2g.large	2	—	32	Up to 4,750	Up to 10 Gbps
db.r6g – Memory-optimized instance classes powered by AWS Graviton2 processors					
db.r6g.16xlarge	64	—	512	19,000	25 Gbps
db.r6g.12xlarge	48	—	384	13,500	20 Gbps
db.r6g.8xlarge	32	—	256	9,000	12 Gbps
db.r6g.4xlarge	16	—	128	4,750	Up to 10 Gbps
db.r6g.2xlarge	8	—	64	Up to 4,750	Up to 10 Gbps
db.r6g.xlarge	4	—	32	Up to 4,750	Up to 10 Gbps
db.r6g.large	2	—	16	Up to 4,750	Up to 10 Gbps
db.r5 – latest generation memory optimized instance classes					
db.r5.24xlarge	96	347	768	19,000	25 Gbps
db.r5.16xlarge	64	264	512	13,600	20 Gbps
db.r5.12xlarge	48	173	384	9,500	10 Gbps
db.r5.8xlarge	32	132	256	6,800	10 Gbps
db.r5.4xlarge	16	71	128	4,750	Up to 10 Gbps
db.r5.2xlarge	8	38	64	Up to 4,750	Up to 10 Gbps
db.r5.xlarge	4	19	32	Up to 4,750	Up to 10 Gbps
db.r5.large	2	10	16	Up to 4,750	Up to 10 Gbps
db.r4 – memory optimized instance classes					
db.r4.16xlarge	64	195	488	14,000	25 Gbps
db.r4.8xlarge	32	99	244	7,000	10 Gbps
db.r4.4xlarge	16	53	122	3,500	Up to 10 Gbps
db.r4.2xlarge	8	27	61	1,700	Up to 10 Gbps
db.r4.xlarge	4	13.5	30.5	850	Up to 10 Gbps
db.r4.large	2	7	15.25	425	Up to 10 Gbps
db.r3 – memory optimized instance classes					
db.r3.8xlarge	32	104	244	—	10 Gbps
db.r3.4xlarge	16	52	122	2,000	High
db.r3.2xlarge	8	26	61	1,000	High

Instance class	vCPU	ECU	Memory (GiB)	Max. bandwidth (mbps) of local storage	Network performance
db.r3.xlarge	4	13	30.5	500	Moderate
db.r3.large	2	6.5	15.25	—	Moderate
db.t4g – Newest generation burstable performance instance classes					
db.t4g.large	2	—	8	Up to 2,780	Up to 5 Gbps
db.t4g.medium	2	—	4	Up to 2,085	Up to 5 Gbps
db.t3 – Next generation burstable performance instance classes					
db.t3.large	2	Variable	8	Up to 2,048	Up to 5 Gbps
db.t3.medium	2	Variable	4	Up to 1,536	Up to 5 Gbps
db.t3.small	2	Variable	2	Up to 1,536	Up to 5 Gbps
db.t2 – burstable performance instance classes					
db.t2.medium	2	Variable	4	—	Moderate
db.t2.small	1	Variable	2	—	Low

** The r3.8xlarge instance doesn't have dedicated EBS bandwidth and therefore doesn't offer EBS optimization. On this instance, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

Amazon Aurora storage and reliability

Following, you can learn about the Aurora storage subsystem. Aurora uses a distributed and shared storage architecture that is an important factor in performance, scalability, and reliability for Aurora clusters.

Topics

- [Overview of Aurora storage \(p. 64\)](#)
- [What the cluster volume contains \(p. 65\)](#)
- [How Aurora storage automatically resizes \(p. 65\)](#)
- [How Aurora data storage is billed \(p. 65\)](#)
- [Amazon Aurora reliability \(p. 66\)](#)

Overview of Aurora storage

Aurora data is stored in the *cluster volume*, which is a single, virtual volume that uses solid state drives (SSDs). A cluster volume consists of copies of the data across three Availability Zones in a single AWS Region. Because the data is automatically replicated across Availability Zones, your data is highly durable with less possibility of data loss. This replication also ensures that your database is more available during a failover. It does so because the data copies already exist in the other Availability Zones and continue to serve data requests to the DB instances in your DB cluster. The amount of replication is independent of the number of DB instances in your cluster.

What the cluster volume contains

The Aurora cluster volume contains all your user data, schema objects, and internal metadata such as the system tables and the binary log. For example, Aurora stores all the tables, indexes, binary large objects (BLOBs), stored procedures, and so on for an Aurora cluster in the cluster volume.

The Aurora shared storage architecture makes your data independent from the DB instances in the cluster. For example, you can add a DB instance quickly because Aurora doesn't make a new copy of the table data. Instead, the DB instance connects to the shared volume that already contains all your data. You can remove a DB instance from a cluster without removing any of the underlying data from the cluster. Only when you delete the entire cluster does Aurora remove the data.

How Aurora storage automatically resizes

Aurora cluster volumes automatically grow as the amount of data in your database increases. The maximum size of for an Aurora cluster volume is 128 tebibytes (TiB) or 64 TiB, depending on the DB engine version. For details about the maximum size for a specific version, see [Amazon Aurora size limits \(p. 1813\)](#). This automatic storage scaling is combined with a high-performance and highly distributed storage subsystem. These make Aurora a good choice for your important enterprise data when your main objectives are reliability and high availability.

To display the volume status, see [Displaying volume status for an Aurora MySQL DB cluster \(p. 837\)](#) or [Displaying volume status for an Aurora PostgreSQL DB cluster \(p. 1367\)](#). For ways to balance storage costs against other priorities, [Storage scaling \(p. 396\)](#) describes how to monitor the Amazon Aurora metrics `AuroraVolumeBytesLeftTotal` and `VolumeBytesUsed` in CloudWatch.

When Aurora data is removed, the space allocated for that data is freed. Examples of removing data include dropping or truncating a table. This automatic reduction in storage usage helps you to minimize storage charges.

Note

The storage limits and dynamic resizing behavior discussed here applies to persistent tables and other data stored in the cluster volume. Data for temporary tables is stored in the local DB instance and its maximum size depends on the instance class that you use.

Some storage features, such as the maximum size of a cluster volume and automatic resizing when data is deleted, depend on the Aurora version of your cluster. For more information, see [Storage scaling \(p. 396\)](#). You can also learn how to avoid storage issues and how to monitor the allocated storage and free space in your cluster.

How Aurora data storage is billed

Even though an Aurora cluster volume can grow up to 128 tebibytes (TiB), you are only charged for the space that you use in an Aurora cluster volume. In earlier Aurora versions, the cluster volume could reuse space that was freed up when you deleted data, but the allocated storage space would never decrease. Starting in Aurora MySQL 2.09.0 and 1.23.0, and Aurora PostgreSQL 3.3.0 and 2.6.0, when Aurora data is removed, such as by dropping a table or database, the overall allocated space decreases by a comparable amount. Thus, you can reduce storage charges by deleting tables, indexes, databases, and so on that you no longer need.

Tip

For earlier versions without the dynamic resizing feature, resetting the storage usage for a cluster involved doing a logical dump and restoring to a new cluster. That operation can take a long time for a substantial volume of data. If you encounter this situation, consider upgrading your cluster to a version that supports volume shrinking.

For pricing information about Aurora data storage, see [Amazon RDS for Aurora Pricing](#).

For information about how to minimize storage charges by monitoring storage usage for your cluster, see [Storage scaling \(p. 396\)](#). For pricing information about Aurora data storage, see [Amazon RDS for Aurora pricing](#).

Amazon Aurora reliability

Aurora is designed to be reliable, durable, and fault tolerant. You can architect your Aurora DB cluster to improve availability by doing things such as adding Aurora Replicas and placing them in different Availability Zones, and also Aurora includes several automatic features that make it a reliable database solution.

Topics

- [Storage auto-repair \(p. 66\)](#)
- [Survivable cache warming \(p. 66\)](#)
- [Crash recovery \(p. 66\)](#)

Storage auto-repair

Because Aurora maintains multiple copies of your data in three Availability Zones, the chance of losing data as a result of a disk failure is greatly minimized. Aurora automatically detects failures in the disk volumes that make up the cluster volume. When a segment of a disk volume fails, Aurora immediately repairs the segment. When Aurora repairs the disk segment, it uses the data in the other volumes that make up the cluster volume to ensure that the data in the repaired segment is current. As a result, Aurora avoids data loss and reduces the need to perform a point-in-time restore to recover from a disk failure.

Survivable cache warming

Aurora "warms" the buffer pool cache when a database starts up after it has been shut down or restarted after a failure. That is, Aurora preloads the buffer pool with the pages for known common queries that are stored in an in-memory page cache. This provides a performance gain by bypassing the need for the buffer pool to "warm up" from normal database use.

The Aurora page cache is managed in a separate process from the database, which allows the page cache to survive independently of the database. In the unlikely event of a database failure, the page cache remains in memory, which ensures that the buffer pool is warmed with the most current state when the database restarts.

Crash recovery

Aurora is designed to recover from a crash almost instantaneously and continue to serve your application data without the binary log. Aurora performs crash recovery asynchronously on parallel threads, so that your database is open and available immediately after a crash.

For more information about crash recovery, see [Fault tolerance for an Aurora DB cluster \(p. 69\)](#).

The following are considerations for binary logging and crash recovery on Aurora MySQL:

- Enabling binary logging on Aurora directly affects the recovery time after a crash, because it forces the DB instance to perform binary log recovery.
- The type of binary logging used affects the size and efficiency of logging. For the same amount of database activity, some formats log more information than others in the binary logs. The following settings for the `binlog_format` parameter result in different amounts of log data:
 - `ROW` – The most log data

- **STATEMENT** – The least log data
- **MIXED** – A moderate amount of log data that usually provides the best combination of data integrity and performance

The amount of binary log data affects recovery time. If there is more data logged in the binary logs, the DB instance must process more data during recovery, which increases recovery time.

- Aurora does not need the binary logs to replicate data within a DB cluster or to perform point in time restore (PITR).
- If you don't need the binary log for external replication (or an external binary log stream), we recommend that you set the `binlog_format` parameter to `OFF` to disable binary logging. Doing so reduces recovery time.

For more information about Aurora binary logging and replication, see [Replication with Amazon Aurora \(p. 70\)](#). For more information about the implications of different MySQL replication types, see [Advantages and disadvantages of statement-based and row-based replication](#) in the MySQL documentation.

Amazon Aurora security

Security for Amazon Aurora is managed at three levels:

- To control who can perform Amazon RDS management actions on Aurora DB clusters and DB instances, you use AWS Identity and Access Management (IAM). When you connect to AWS using IAM credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see [Identity and access management in Amazon Aurora \(p. 1724\)](#).

If you are using IAM to access the Amazon RDS console, you must first log on to the AWS Management Console with your IAM user credentials, and then go to the Amazon RDS console at <https://console.aws.amazon.com/rds>.

- Aurora DB clusters must be created in a virtual private cloud (VPC) based on the Amazon VPC service. To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora DB clusters in a VPC, you use a VPC security group. You can make these endpoint and port connections using Transport Layer Security (TLS)/Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see [Amazon Virtual Private Cloud VPCs and Amazon Aurora \(p. 1787\)](#).
- To authenticate logins and permissions for an Amazon Aurora DB cluster, you can take either of the following approaches, or a combination of them.
 - You can take the same approach as with a stand-alone DB instance of MySQL or PostgreSQL.

Techniques for authenticating logins and permissions for stand-alone DB instances of MySQL or PostgreSQL, such as using SQL commands or modifying database schema tables, also work with Aurora. For more information, see [Security with Amazon Aurora MySQL \(p. 774\)](#) or [Security with Amazon Aurora PostgreSQL \(p. 1276\)](#).

- You can also use IAM database authentication for Aurora MySQL.

With IAM database authentication, you authenticate to your Aurora MySQL DB cluster by using an IAM user or IAM role and an authentication token. An *authentication token* is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see [IAM database authentication \(p. 1743\)](#).

For information about configuring security, see [Security in Amazon Aurora \(p. 1706\)](#).

Using SSL with Aurora DB clusters

Amazon Aurora DB clusters support Secure Sockets Layer (SSL) connections from applications using the same process and public key as Amazon RDS DB instances. For more information, see [Security with Amazon Aurora MySQL \(p. 774\)](#), [Security with Amazon Aurora PostgreSQL \(p. 1276\)](#), or [Using TLS/SSL with Aurora Serverless v1 \(p. 150\)](#).

High availability for Amazon Aurora

The Amazon Aurora architecture involves separation of storage and compute. Aurora includes some high availability features that apply to the data in your DB cluster. The data remains safe even if some or all of the DB instances in the cluster become unavailable. Other high availability features apply to the DB instances. These features help to make sure that one or more DB instances are ready to handle database requests from your application.

Topics

- [High availability for Aurora data \(p. 68\)](#)
- [High availability for Aurora DB instances \(p. 68\)](#)
- [High availability across AWS Regions with Aurora global databases \(p. 69\)](#)
- [Fault tolerance for an Aurora DB cluster \(p. 69\)](#)

High availability for Aurora data

Aurora stores copies of the data in a DB cluster across multiple Availability Zones in a single AWS Region. Aurora stores these copies regardless of whether the instances in the DB cluster span multiple Availability Zones. For more information on Aurora, see [Managing an Amazon Aurora DB cluster \(p. 367\)](#).

When data is written to the primary DB instance, Aurora synchronously replicates the data across Availability Zones to six storage nodes associated with your cluster volume. Doing so provides data redundancy, eliminates I/O freezes, and minimizes latency spikes during system backups. Running a DB instance with high availability can enhance availability during planned system maintenance, and help protect your databases against failure and Availability Zone disruption. For more information on Availability Zones, see [Regions and Availability Zones \(p. 11\)](#).

High availability for Aurora DB instances

For a cluster using single-master replication, after you create the primary instance, you can create up to 15 read-only Aurora Replicas. The Aurora Replicas are also known as reader instances.

During day-to-day operations, you can offload some of the work for read-intensive applications by using the reader instances to process `SELECT` queries. When a problem affects the primary instance, one of these reader instances takes over as the primary instance. This mechanism is known as *failover*. Many Aurora features apply to the failover mechanism. For example, Aurora detects database problems and activates the failover mechanism automatically when necessary. Aurora also has features that reduce the time for failover to complete. Doing so minimizes the time that the database is unavailable for writing during a failover.

To use a connection string that stays the same even when a failover promotes a new primary instance, you connect to the cluster endpoint. The *cluster endpoint* always represents the current primary instance in the cluster. For more information about the cluster endpoint, see [Amazon Aurora connection management \(p. 32\)](#).

Tip

Within each AWS Region, Availability Zones represent locations that are distinct from each other to provide isolation in case of outages. We recommend that you distribute the primary instance and reader instances in your DB cluster over multiple Availability Zones to improve the availability of your DB cluster. That way, an issue that affects an entire Availability Zone doesn't cause an outage for your cluster.

You can set up a Multi-AZ cluster by making a simple choice when you create the cluster. The choice is simple whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API. You can also make an existing Aurora cluster into a Multi-AZ cluster by adding a new reader instance and specifying a different Availability Zone.

High availability across AWS Regions with Aurora global databases

For high availability across multiple AWS Regions, you can set up Aurora global databases. Each Aurora global database spans multiple AWS Regions, enabling low latency global reads and disaster recovery from outages across an AWS Region. Aurora automatically handles replicating all data and updates from the primary AWS Region to each of the secondary Regions. For more information, see [Using Amazon Aurora global databases \(p. 225\)](#).

Fault tolerance for an Aurora DB cluster

An Aurora DB cluster is fault tolerant by design. The cluster volume spans multiple Availability Zones in a single AWS Region, and each Availability Zone contains a copy of the cluster volume data. This functionality means that your DB cluster can tolerate a failure of an Availability Zone without any loss of data and only a brief interruption of service.

If the primary instance in a DB cluster using single-master replication fails, Aurora automatically fails over to a new primary instance in one of two ways:

- By promoting an existing Aurora Replica to the new primary instance
- By creating a new primary instance

If the DB cluster has one or more Aurora Replicas, then an Aurora Replica is promoted to the primary instance during a failure event. A failure event results in a brief interruption, during which read and write operations fail with an exception. However, service is typically restored in less than 120 seconds, and often less than 60 seconds. To increase the availability of your DB cluster, we recommend that you create at least one or more Aurora Replicas in two or more different Availability Zones.

Tip

In Aurora MySQL 2.10 and higher, you can improve availability during a failover by having more than one reader DB instance in a cluster. In Aurora MySQL 2.10 and higher, Aurora restarts only the writer DB instance and the failover target during a failover. Other reader DB instances in the cluster remain available to continue processing queries through connections to the reader endpoint.

You can customize the order in which your Aurora Replicas are promoted to the primary instance after a failure by assigning each replica a priority. Priorities range from 0 for the first priority to 15 for the last priority. If the primary instance fails, Amazon RDS promotes the Aurora Replica with the better priority to the new primary instance. You can modify the priority of an Aurora Replica at any time. Modifying the priority doesn't trigger a failover.

More than one Aurora Replica can share the same priority, resulting in promotion tiers. If two or more Aurora Replicas share the same priority, then Amazon RDS promotes the replica that is largest in size. If two or more Aurora Replicas share the same priority and size, then Amazon RDS promotes an arbitrary replica in the same promotion tier.

If the DB cluster doesn't contain any Aurora Replicas, then the primary instance is recreated in the same AZ during a failure event. A failure event results in an interruption during which read and write operations fail with an exception. Service is restored when the new primary instance is created, which typically takes less than 10 minutes. Promoting an Aurora Replica to the primary instance is much faster than creating a new primary instance.

Suppose that the primary instance in your cluster is unavailable because of an outage that affects an entire AZ. In this case, the way to bring a new primary instance online depends on whether your cluster uses a multi-AZ configuration. If the cluster contains any reader instances in other AZs, Aurora uses the failover mechanism to promote one of those reader instances to be the new primary instance. If your provisioned cluster only contains a single DB instance, or if the primary instance and all reader instances are in the same AZ, you must manually create one or more new DB instances in another AZ. If your cluster uses Aurora Serverless, Aurora automatically creates a new DB instance in another AZ. However, this process involves a host replacement and thus takes longer than a failover.

Note

Amazon Aurora also supports replication with an external MySQL database, or an RDS MySQL DB instance. For more information, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\)](#) (p. 932).

Replication with Amazon Aurora

There are several replication options with Aurora. Each Aurora DB cluster has built-in replication between multiple DB instances in the same cluster. You can also set up replication with your Aurora cluster as the source or the target. When you replicate data into or out of an Aurora cluster, you can choose between built-in features such as Aurora global databases or the traditional replication mechanisms for the MySQL or PostgreSQL DB engines. You can choose the appropriate options based on which one provides the right combination of high availability, convenience, and performance for your needs. The following sections explain how and when to choose each technique.

Topics

- [Aurora Replicas](#) (p. 70)
- [Replication with Aurora MySQL](#) (p. 71)
- [Replication with Aurora PostgreSQL](#) (p. 72)

Aurora Replicas

When you create a second, third, and so on DB instance in an Aurora provisioned DB cluster, Aurora automatically sets up replication from the writer DB instance to all the other DB instances. These other DB instances are read-only and are known as Aurora Replicas. We also refer to them as reader instances when discussing the ways that you can combine writer and reader DB instances within a cluster.

Aurora Replicas have two main purposes. You can issue queries to them to scale the read operations for your application. You typically do so by connecting to the reader endpoint of the cluster. That way, Aurora can spread the load for read-only connections across as many Aurora Replicas as you have in the cluster. Aurora Replicas also help to increase availability. If the writer instance in a cluster becomes unavailable, Aurora automatically promotes one of the reader instances to take its place as the new writer.

An Aurora DB cluster can contain up to 15 Aurora Replicas. The Aurora Replicas can be distributed across the Availability Zones that a DB cluster spans within an AWS Region.

The data in your DB cluster has its own high availability and reliability features, independent of the DB instances in the cluster. If you aren't familiar with Aurora storage features, see [Overview of Aurora](#)

storage (p. 64). The DB cluster volume is physically made up of multiple copies of the data for the DB cluster. The primary instance and the Aurora Replicas in the DB cluster all see the data in the cluster volume as a single logical volume.

As a result, all Aurora Replicas return the same data for query results with minimal replica lag. This lag is usually much less than 100 milliseconds after the primary instance has written an update. Replica lag varies depending on the rate of database change. That is, during periods where a large amount of write operations occur for the database, you might see an increase in replica lag.

Aurora Replicas work well for read scaling because they are fully dedicated to read operations on your cluster volume. Write operations are managed by the primary instance. Because the cluster volume is shared among all DB instances in your DB cluster, minimal additional work is required to replicate a copy of the data for each Aurora Replica.

To increase availability, you can use Aurora Replicas as failover targets. That is, if the primary instance fails, an Aurora Replica is promoted to the primary instance. There is a brief interruption during which read and write requests made to the primary instance fail with an exception. When this happens, some of the Aurora Replicas might be rebooted, depending on the DB engine version. For information about the rebooting behavior of different Aurora DB engine versions, see [Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance \(p. 451\)](#). Promoting an Aurora Replica this way is much faster than recreating the primary instance. If your Aurora DB cluster doesn't include any Aurora Replicas, then your DB cluster isn't available while your DB instance is recovering from the failure.

For high-availability scenarios, we recommend that you create one or more Aurora Replicas. These should be of the same DB instance class as the primary instance and in different Availability Zones for your Aurora DB cluster. For more information about Aurora Replicas as failover targets, see [Fault tolerance for an Aurora DB cluster \(p. 69\)](#).

When an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements running on the Aurora Replica that is being deleted, there is a three minute grace period. Existing statements can finish gracefully during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

You can't create an encrypted Aurora Replica for an unencrypted Aurora DB cluster. You can't create an unencrypted Aurora Replica for an encrypted Aurora DB cluster.

Tip

You can use Aurora Replicas within an Aurora cluster as your only form of replication to keep your data highly available. You can also combine the built-in Aurora replication with the other types of replication. Doing so can help to provide an extra level of high availability and geographic distribution of your data.

For details on how to create an Aurora Replica, see [Adding Aurora Replicas to a DB cluster \(p. 392\)](#).

Replication with Aurora MySQL

In addition to Aurora Replicas, you have the following options for replication with Aurora MySQL:

- Aurora MySQL DB clusters in different AWS Regions.
 - You can replicate data across multiple Regions by using an Aurora global database. For details, see [High availability across AWS Regions with Aurora global databases \(p. 69\)](#)
 - You can create an Aurora read replica of an Aurora MySQL DB cluster in a different AWS Region, by using MySQL binary log (binlog) replication. Each cluster can have up to five read replicas created this way, each in a different Region.
- Two Aurora MySQL DB clusters in the same Region, by using MySQL binary log (binlog) replication.
- An RDS for MySQL DB instance as the source of data and an Aurora MySQL DB cluster, by creating an Aurora read replica of an RDS for MySQL DB instance. Typically, you use this approach for migration to Aurora MySQL, rather than for ongoing replication.

For more information about replication with Aurora MySQL, see [Single-master replication with Amazon Aurora MySQL \(p. 918\)](#).

Replication with Aurora PostgreSQL

In addition to Aurora Replicas, you have the following options for replication with Aurora PostgreSQL:

- An Aurora primary DB cluster in one Region and up to five read-only secondary DB clusters in different Regions by using an Aurora global database. Aurora PostgreSQL doesn't support cross-Region Aurora Replicas. However, you can use Aurora global database to scale your Aurora PostgreSQL DB cluster's read capabilities to more than one AWS Region and to meet availability goals. For more information, see [Using Amazon Aurora global databases \(p. 225\)](#).
- Two Aurora PostgreSQL DB clusters in the same Region, by using PostgreSQL's logical replication feature.
- An RDS for PostgreSQL DB instance as the source of data and an Aurora PostgreSQL DB cluster, by creating an Aurora read replica of an RDS for PostgreSQL DB instance. Typically, you use this approach for migration to Aurora PostgreSQL, rather than for ongoing replication.

For more information about replication with Aurora PostgreSQL, see [Replication with Amazon Aurora PostgreSQL \(p. 1431\)](#).

DB instance billing for Aurora

Amazon RDS instances in an Aurora cluster are billed based on the following components:

- DB instance hours (per hour) – Based on the DB instance class of the DB instance (for example, db.t2.small or db.m4.large). Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is billed in one second increments, with a minimum of 10 minutes. For more information, see [Aurora DB instance classes \(p. 54\)](#).
- Storage (per GiB per month) – Storage capacity that you have provisioned to your DB instance. If you scale your provisioned storage capacity within the month, your bill is prorated. For more information, see [Amazon Aurora storage and reliability \(p. 64\)](#).
- I/O requests (per 1 million requests per month) – Total number of storage I/O requests that you have made in a billing cycle.
- Backup storage (per GiB per month) – *Backup storage* is the storage that is associated with automated database backups and any active database snapshots that you have taken. Increasing your backup retention period or taking additional database snapshots increases the backup storage consumed by your database. Per second billing doesn't apply to backup storage (metered in GB-month).

For more information, see [Backing up and restoring an Amazon Aurora DB cluster \(p. 490\)](#).

- Data transfer (per GB) – Data transfer in and out of your DB instance from or to the internet and other AWS Regions.

Amazon RDS provides the following purchasing options to enable you to optimize your costs based on your needs:

- **On-Demand Instances** – Pay by the hour for the DB instance hours that you use. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is now billed in one second increments, with a minimum of 10 minutes.
- **Reserved Instances** – Reserve a DB instance for a one-year or three-year term and get a significant discount compared to the on-demand DB instance pricing. With Reserved Instance usage, you can

launch, delete, start, or stop multiple instances within an hour and get the Reserved Instance benefit for all of the instances.

For Aurora pricing information, see the [Aurora pricing page](#).

Topics

- [On-Demand DB instances for Aurora \(p. 74\)](#)
- [Reserved DB instances for Aurora \(p. 75\)](#)

On-Demand DB instances for Aurora

Amazon RDS on-demand DB instances are billed based on the class of the DB instance (for example, db.t2.small or db.m4.large). For Amazon RDS pricing information, see the [Amazon RDS product page](#).

Billing starts for a DB instance as soon as the DB instance is available. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. Amazon RDS usage is billed in one-second increments, with a minimum of 10 minutes. In the case of billable configuration change, such as scaling compute or storage capacity, you're charged a 10-minute minimum. Billing continues until the DB instance terminates, which occurs when you delete the DB instance or if the DB instance fails.

If you no longer want to be charged for your DB instance, you must stop or delete it to avoid being billed for additional DB instance hours. For more information about the DB instance states for which you are billed, see [Viewing DB instance status in an Aurora cluster \(p. 555\)](#).

Stopped DB instances

While your DB instance is stopped, you're charged for provisioned storage, including Provisioned IOPS. You are also charged for backup storage, including storage for manual snapshots and automated backups within your specified retention window. You aren't charged for DB instance hours.

Multi-AZ DB instances

If you specify that your DB instance should be a Multi-AZ deployment, you're billed according to the Multi-AZ pricing posted on the Amazon RDS pricing page.

Reserved DB instances for Aurora

Using reserved DB instances, you can reserve a DB instance for a one- or three-year term. Reserved DB instances provide you with a significant discount compared to on-demand DB instance pricing. Reserved DB instances are not physical instances, but rather a billing discount applied to the use of certain on-demand DB instances in your account. Discounts for reserved DB instances are tied to instance type and AWS Region.

The general process for working with reserved DB instances is: First get information about available reserved DB instance offerings, then purchase a reserved DB instance offering, and finally get information about your existing reserved DB instances.

Overview of reserved DB instances

When you purchase a reserved DB instance in Amazon RDS, you purchase a commitment to getting a discounted rate, on a specific DB instance type, for the duration of the reserved DB instance. To use an Amazon RDS reserved DB instance, you create a new DB instance just like you do for an on-demand instance. The new DB instance that you create must match the specifications of the reserved DB instance. If the specifications of the new DB instance match an existing reserved DB instance for your account, you are billed at the discounted rate offered for the reserved DB instance. Otherwise, the DB instance is billed at an on-demand rate.

You can modify a reserved DB instance. If the modification is within the specifications of the reserved DB instance, part or all of the discount still applies to the modified DB instance. If the modification is outside the specifications, such as changing the instance class, the discount no longer applies. For more information, see [Size-flexible reserved DB instances \(p. 76\)](#).

For more information about reserved DB instances, including pricing, see [Amazon RDS reserved instances](#).

Offering types

Reserved DB instances are available in three varieties—No Upfront, Partial Upfront, and All Upfront—that let you optimize your Amazon RDS costs based on your expected usage.

No Upfront

This option provides access to a reserved DB instance without requiring an upfront payment. Your No Upfront reserved DB instance bills a discounted hourly rate for every hour within the term, regardless of usage, and no upfront payment is required. This option is only available as a one-year reservation.

Partial Upfront

This option requires a part of the reserved DB instance to be paid upfront. The remaining hours in the term are billed at a discounted hourly rate, regardless of usage. This option is the replacement for the previous Heavy Utilization option.

All Upfront

Full payment is made at the start of the term, with no other costs incurred for the remainder of the term regardless of the number of hours used.

If you are using consolidated billing, all the accounts in the organization are treated as one account. This means that all accounts in the organization can receive the hourly cost benefit of reserved DB instances that are purchased by any other account. For more information about consolidated billing, see [Amazon RDS reserved DB instances](#) in the *AWS Billing and Cost Management User Guide*.

Size-flexible reserved DB instances

When you purchase a reserved DB instance, one thing that you specify is the instance class, for example db.m4.large. For more information about instance classes, see [Aurora DB instance classes \(p. 54\)](#).

If you have a DB instance, and you need to scale it to larger capacity, your reserved DB instance is automatically applied to your scaled DB instance. That is, your reserved DB instances are automatically applied across all DB instance class sizes. Size-flexible reserved DB instances are available for DB instances with the same AWS Region and database engine. Size-flexible reserved DB instances can only scale in their instance class type. For example, a reserved DB instance for a db.m4.large can apply to a db.m4.xlarge, but not to a db.m5.large, because db.m4 and db.m5 are different instance class types.

Reserved DB instance benefits also apply for both Multi-AZ and Single-AZ configurations. Flexibility means that you can move freely between configurations within the same DB instance class type. For example, you can move from a Single-AZ deployment running on one large DB instance (four normalized units) to a Multi-AZ deployment running on two small DB instances ($2 \times 2 = 4$ normalized units).

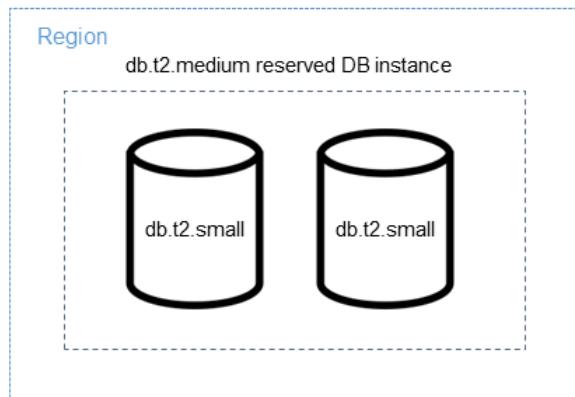

Size-flexible reserved DB instances are available for the following Aurora database engines:

- Aurora MySQL
- Aurora PostgreSQL

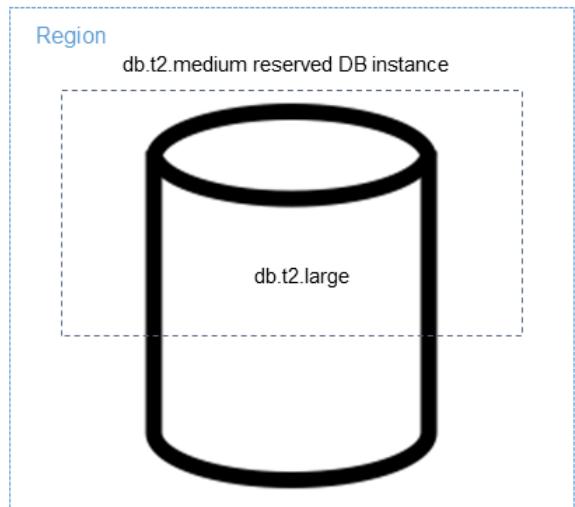

You can compare usage for different reserved DB instance sizes by using normalized units. For example, one unit of usage on two db.m3.large DB instances is equivalent to eight normalized units of usage on one db.m3.small. The following table shows the number of normalized units for each DB instance size.

Instance size	Single-AZ normalized units	Multi-AZ normalized units
micro	0.5	1
small	1	2
medium	2	4
large	4	8
xlarge	8	16
2xlarge	16	32
4xlarge	32	64
8xlarge	64	128
10xlarge	80	160
12xlarge	96	192
16xlarge	128	256
24xlarge	192	384

For example, suppose that you purchase a db.t2.medium reserved DB instance, and you have two running db.t2.small DB instances in your account in the same AWS Region. In this case, the billing benefit is applied in full to both instances.

Alternatively, if you have one db.t2.large instance running in your account in the same AWS Region, the billing benefit is applied to 50 percent of the usage of the DB instance.

Reserved DB instance billing example

The price for a reserved DB instance doesn't include regular costs associated with storage, backups, and I/O. The following example illustrates the total cost per month for a reserved DB instance:

- An Aurora MySQL reserved Single-AZ db.r4.large DB instance class in US East (N. Virginia) at a cost of \$0.19 per hour, or \$138.70 per month
- Aurora storage at a cost of \$0.10 per GiB per month (assume \$45.60 per month for this example)
- Aurora I/O at a cost of \$0.20 per 1 million requests (assume \$20 per month for this example)
- Aurora backup storage at \$0.021 per GiB per month (assume \$30 per month for this example)

Add all of these options ($\$138.70 + \$45.60 + \$20 + \30) with the reserved DB instance, and the total cost per month is \$234.30.

If you chose to use an on-demand DB instance instead of a reserved DB instance, an Aurora MySQL Single-AZ db.r4.large DB instance class in US East (N. Virginia) costs \$0.29 per hour, or \$217.50 per month. So, for an on-demand DB instance, add all of these options ($\$217.50 + \$45.60 + \$20 + \30), and the total cost per month is \$313.10. You save nearly \$79 per month by using the reserved DB instance.

Note

The prices in this example are sample prices and might not match actual prices.
For Aurora pricing information, see the [Aurora pricing page](#).

Deleting a reserved DB instance

The terms for a reserved DB instance involve a one-year or three-year commitment. You can't cancel a reserved DB instance. However, you can delete a DB instance that is covered by a reserved DB instance discount. The process for deleting a DB instance that is covered by a reserved DB instance discount is the same as for any other DB instance.

You're billed for the upfront costs regardless of whether you use the resources.

If you delete a DB instance that is covered by a reserved DB instance discount, you can launch another DB instance with compatible specifications. In this case, you continue to get the discounted rate during the reservation term (one or three years).

Working with reserved DB instances

You can use the AWS Management Console, the AWS CLI, and the RDS API to work with reserved DB instances.

Console

You can use the AWS Management Console to work with reserved DB instances as shown in the following procedures.

To get pricing and information about available reserved DB instance offerings

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Reserved instances**.
3. Choose **Purchase Reserved DB Instance**.
4. For **Product description**, choose the DB engine and licensing type.
5. For **DB instance class**, choose the DB instance class.
6. For **Multi-AZ deployment**, choose whether you want a Multi-AZ deployment.

Note

Reserved Amazon Aurora instances always have the **Multi-AZ deployment** option set to **No**. When you create an Amazon Aurora DB cluster from your reserved DB instance, the DB cluster is automatically created as Multi-AZ. You must purchase a reserved DB instance for each DB instance you plan to use, including Aurora Replicas.

7. For **Term**, choose the length of time you want the DB instance reserved.
8. For **Offering type**, choose the offering type.

After you select the offering type, you can see the pricing information.

Important

Choose **Cancel** to avoid purchasing the reserved DB instance and incurring any charges.

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering as shown in the following procedure.

To purchase a reserved DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Reserved instances**.
3. Choose **Purchase Reserved DB Instance**.
4. For **Product description**, choose the DB engine and licensing type.
5. For **DB instance class**, choose the DB instance class.
6. For **Multi-AZ deployment**, choose whether you want a Multi-AZ deployment.

Note

Reserved Amazon Aurora instances always have the **Multi-AZ deployment** option set to **No**. When you create an Amazon Aurora DB cluster from your reserved DB instance, the DB cluster is automatically created as Multi-AZ. You must purchase a reserved DB instance for each DB instance you plan to use, including Aurora Replicas.

7. For **Term**, choose the length of time you want the DB instance reserved.
8. For **Offering type**, choose the offering type.

After you choose the offering type, you can see the pricing information.

The screenshot shows the 'Purchase Reserved DB Instances' wizard. The first step, 'Options', is displayed. It includes fields for Product description (set to 'aurora-mysql'), DB instance class (set to 'db.r5.xlarge — 4 vCPU, 32 GiB RAM'), Multi AZ deployment (radio button for 'No' selected), Term (set to '1 year'), Offering type (set to 'Partial Upfront'), and a Reserved Id field. The second step, 'Pricing details', is partially visible below it. It shows One-time payment (per instance) and Total one-time payment fields, both with redacted values. It also shows Usage charges (hourly) and a note about additional taxes. The 'Pricing details' step has a 'Cancel' and 'Continue' button at the bottom.

9. (Optional) You can assign your own identifier to the reserved DB instances that you purchase to help you track them. For **Reserved Id**, type an identifier for your reserved DB instance.
10. Choose **Continue**.

The **Purchase Reserved DB Instances** dialog box appears, with a summary of the reserved DB instance attributes that you've selected and the payment due.

The screenshot shows the 'Purchase Reserved DB Instances' dialog box. At the top, there's a breadcrumb navigation: RDS > Reserved instances > Purchase Reserved DB Instances. The main title is 'Purchase Reserved DB Instances'. Below it is a 'Summary of Purchase' section with the following details:

Region	US West (Oregon)
Product Description	aurora-mysql
DB Instance Class	db.r5.xlarge
Offering Type	Partial Upfront
Multi AZ Deployment	No
Term	1 year
Reserved DB Instance	default
Quantity	1
Price Per Instance	[Redacted]
Total Payment Due Now	[Redacted]

At the bottom of the summary section, there's a warning message: **⚠️ Purchasing this Reserved DB Instance will charge [Redacted] to the payment method associated with this Amazon Web Services account. Are you sure you would like to proceed?**

At the very bottom of the dialog box are three buttons: **Cancel**, **Back**, and **Order** (which is highlighted in orange).

11. On the confirmation page, review your reserved DB instance. If the information is correct, choose **Order** to purchase the reserved DB instance.

Alternatively, choose **Back** to edit your reserved DB instance.

After you have purchased reserved DB instances, you can get information about your reserved DB instances as shown in the following procedure.

To get information about reserved DB instances for your AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the Navigation pane, choose **Reserved instances**.

The reserved DB instances for your account appear. To see detailed information about a particular reserved DB instance, choose that instance in the list. You can then see detailed information about that instance in the detail pane at the bottom of the console.

AWS CLI

You can use the AWS CLI to work with reserved DB instances as shown in the following examples.

Example of getting available reserved DB instance offerings

To get information about available reserved DB instance offerings, call the AWS CLI command [describe-reserved-db-instances-offerings](#).

```
aws rds describe-reserved-db-instances-offerings
```

This call returns output similar to the following:

OFFERING	OfferingId	Class	Multi-AZ	Duration	Fixed
Price	Usage Price	Description	Offering Type		
OFFERING	438012d3-4052-4cc7-b2e3-8d3372e0e706	db.m1.large	y	1y	1820.00
USD	0.368	mysql	Partial Upfront		
OFFERING	649fd0c8-cf6d-47a0-bfa6-060f8e75e95f	db.m1.small	n	1y	227.50
USD	0.046	mysql	Partial Upfront		
OFFERING	123456cd-ab1c-47a0-bfa6-12345667232f	db.m1.small	n	1y	162.00
USD	0.00	mysql	All Upfront		
Recurring Charges: Amount Currency Frequency					
Recurring Charges: 0.123 USD Hourly					
OFFERING	123456cd-ab1c-37a0-bfa6-12345667232d	db.m1.large	y	1y	700.00
USD	0.00	mysql	All Upfront		
Recurring Charges: Amount Currency Frequency					
Recurring Charges: 1.25 USD Hourly					
OFFERING	123456cd-ab1c-17d0-bfa6-12345667234e	db.m1.xlarge	n	1y	4242.00
USD	2.42	mysql	No Upfront		

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering.

To purchase a reserved DB instance, use the AWS CLI command [purchase-reserved-db-instances-offering](#) with the following parameters:

- **--reserved-db-instances-offering-id** – The ID of the offering that you want to purchase. See the preceding example to get the offering ID.
- **--reserved-db-instance-id** – You can assign your own identifier to the reserved DB instances that you purchase to help track them.

Example of purchasing a reserved DB instance

The following example purchases the reserved DB instance offering with ID ***649fd0c8-cf6d-47a0-bfa6-060f8e75e95f***, and assigns the identifier of ***MyReservation***.

For Linux, macOS, or Unix:

```
aws rds purchase-reserved-db-instances-offering \
--reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f \
--reserved-db-instance-id MyReservation
```

For Windows:

```
aws rds purchase-reserved-db-instances-offering ^
--reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f ^
--reserved-db-instance-id MyReservation
```

The command returns output similar to the following:

RESERVATION	ReservationId	Class	Multi-AZ	Start Time	Duration
Fixed Price	Usage Price	Count	State	Description	Offering Type
RESERVATION	MyReservation	db.m1.small	y	2011-12-19T00:30:23.247Z	1y
455.00	USD	0.092	1	payment-pending	mysql Partial Upfront

After you have purchased reserved DB instances, you can get information about your reserved DB instances.

To get information about reserved DB instances for your AWS account, call the AWS CLI command [describe-reserved-db-instances](#), as shown in the following example.

Example of getting your reserved DB instances

```
aws rds describe-reserved-db-instances
```

The command returns output similar to the following:

RESERVATION	ReservationId	Class	Multi-AZ	Start Time	Duration
Fixed Price	Usage Price	Count	State	Description	Offering Type
RESERVATION	MyReservation	db.m1.small	y	2011-12-09T23:37:44.720Z	1y
455.00	USD	0.092	1	retired	mysql Partial Upfront

RDS API

You can use the RDS API to work with reserved DB instances:

- To get information about available reserved DB instance offerings, call the Amazon RDS API operation [DescribeReservedDBInstancesOfferings](#).
- After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering. Call the [PurchaseReservedDBInstancesOffering](#) RDS API operation with the following parameters:
 - `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase.
 - `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.
- After you have purchased reserved DB instances, you can get information about your reserved DB instances. Call the [DescribeReservedDBInstances](#) RDS API operation.

Viewing the billing for your reserved DB instances

You can view the billing for your reserved DB instances in the Billing Dashboard in the AWS Management Console.

To view reserved DB instance billing

1. Sign in to the AWS Management Console.
2. From the **account menu** at the upper right, choose **Billing Dashboard**.

3. Choose **Bill Details** at the upper right of the dashboard.
4. Under **AWS Service Charges**, expand **Relational Database Service**.
5. Expand the AWS Region where your reserved DB instances are, for example **US West (Oregon)**.

Your reserved DB instances and their hourly charges for the current month are shown under **Amazon Relational Database Service for Database Engine Reserved Instances**.

Amazon Relational Database Service for MySQL Community Edition Reserved Instances	0.00
MySQL, db.t3.micro reserved instance applied, db.t3.micro instance used	0.00
USD 0.00 hourly fee per MySQL, db.t3.micro instance	0.00

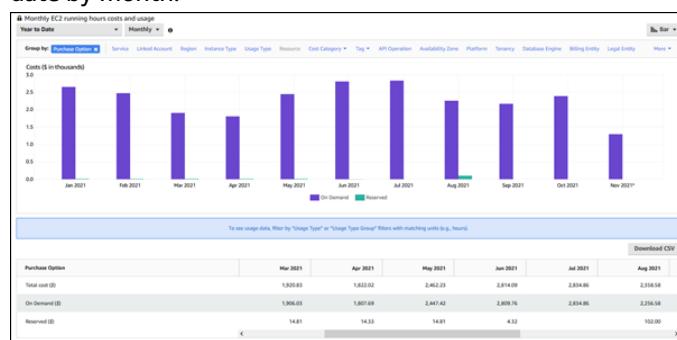

The reserved DB instance in this example was purchased All Upfront, so there are no hourly charges.

6. Choose the **Cost Explorer** (bar graph) icon next to the **Reserved Instances** heading.

The Cost Explorer displays the **Monthly EC2 running hours costs and usage** graph.

7. Clear the **Usage Type Group** filter to the right of the graph.
8. Choose the time period and time unit for which you want to examine usage costs.

The following example shows usage costs for on-demand and reserved DB instances for the year to date by month.

The reserved DB instance costs from January through June 2021 are monthly charges for a Partial Upfront instance, while the cost in August 2021 is a one-time charge for an All Upfront instance.

The reserved instance discount for the Partial Upfront instance expired in June 2021, but the DB instance wasn't deleted. After the expiration date, it was simply charged at the on-demand rate.

Setting up your environment for Amazon Aurora

Before you use Amazon Aurora for the first time, complete the following tasks:

1. [Sign up for AWS \(p. 84\)](#)
2. [Create an IAM user \(p. 84\)](#)
3. [Determine requirements \(p. 86\)](#)
4. [Provide access to the DB cluster in the VPC by creating a security group \(p. 87\)](#)

If you already have an AWS account, know your Aurora requirements, and prefer to use the defaults for IAM and VPC security groups, skip ahead to [Getting started with Amazon Aurora \(p. 89\)](#).

Sign up for AWS

When you sign up for AWS, your AWS account is automatically signed up for all services in AWS, including Amazon RDS. You are charged only for the services that you use.

With Amazon RDS, you pay only for the resources you use. The Amazon RDS DB clusters that you create are live (not running in a sandbox). You incur the standard Amazon RDS usage fees for each DB cluster until you terminate it. For more information about Amazon RDS usage rates, see the [Amazon RDS product page](#). If you are a new AWS customer, you can get started with Amazon RDS for free; for more information, see [AWS free tier](#).

If you have an AWS account already, skip to the next section, [Create an IAM user \(p. 84\)](#).

If you don't have an AWS account, you can use the following procedure to create one.

To create a new AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

Note your AWS account number, because you'll need it for the next task.

Create an IAM user

After you create an AWS account and successfully connect to the AWS Management Console, you can create an AWS Identity and Access Management (IAM) user. Instead of signing in with your AWS root account, we recommend that you use an IAM administrative user with Amazon RDS.

One way to do this is to create a new IAM user and grant it administrator permissions. Alternatively, you can add an existing IAM user to an IAM group with Amazon RDS administrative permissions. You can then access AWS from a special URL using the credentials for the IAM user.

If you signed up for AWS but have not created an IAM user for yourself, you can create one using the IAM console.

To create an administrator user for yourself and add the user to an administrators group (console)

1. Sign in to the [IAM console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

Note

We strongly recommend that you adhere to the best practice of using the **Administrator** IAM user that follows and securely lock away the root user credentials. Sign in as the root user only to perform a few [account and service management tasks](#).

2. In the navigation pane, choose **Users** and then choose **Add user**.
3. For **User name**, enter **Administrator**.
4. Select the check box next to **AWS Management Console access**. Then select **Custom password**, and then enter your new password in the text box.
5. (Optional) By default, AWS requires the new user to create a new password when first signing in. You can clear the check box next to **User must create a new password at next sign-in** to allow the new user to reset their password after they sign in.
6. Choose **Next: Permissions**.
7. Under **Set permissions**, choose **Add user to group**.
8. Choose **Create group**.
9. In the **Create group** dialog box, for **Group name** enter **Administrators**.
10. Choose **Filter policies**, and then select **AWS managed - job function** to filter the table contents.
11. In the policy list, select the check box for **AdministratorAccess**. Then choose **Create group**.

Note

You must activate IAM user and role access to Billing before you can use the **AdministratorAccess** permissions to access the AWS Billing and Cost Management console. To do this, follow the instructions in [step 1 of the tutorial about delegating access to the billing console](#).

12. Back in the list of groups, select the check box for your new group. Choose **Refresh** if necessary to see the group in the list.
13. Choose **Next: Tags**.
14. (Optional) Add metadata to the user by attaching tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM entities](#) in the *IAM User Guide*.
15. Choose **Next: Review** to see the list of group memberships to be added to the new user. When you are ready to proceed, choose **Create user**.

You can use this same process to create more groups and users and to give your users access to your AWS account resources. To learn about using policies that restrict user permissions to specific AWS resources, see [Access management](#) and [Example policies](#).

To sign in as this new IAM user, sign out of the AWS console, then use the following URL, where *your_aws_account_id* is your AWS account number without the hyphens (for example, if your AWS account number is 1234-5678-9012, your AWS account ID is 123456789012):

`https://your_aws_account_id.signin.aws.amazon.com/console/`

Enter the IAM user name and password that you just created. When you're signed in, the navigation bar displays "`your_user_name @ your_aws_account_id`".

If you don't want the URL for your sign-in page to contain your AWS account ID, you can create an account alias. From the IAM dashboard, choose **Customize** and enter an alias, such as your company name. To sign in after you create an account alias, use the following URL:

```
https://your_account_alias.signin.aws.amazon.com/console/
```

To verify the sign-in link for IAM users for your account, open the IAM console and check under **AWS Account Alias** on the dashboard.

You can also create access keys for your AWS account. These access keys can be used to access AWS through the AWS Command Line Interface (AWS CLI) or through the Amazon RDS API. For more information, see [Programmatic access, Installing, updating, and uninstalling the AWS CLI](#), and the [Amazon RDS API reference](#).

Determine requirements

The basic building block of Aurora is the DB cluster. One or more DB instances can belong to a DB cluster. A DB cluster provides a network address called the *cluster endpoint*. Your applications connect to the cluster endpoint exposed by the DB cluster whenever they need to access the databases created in that DB cluster. The information you specify when you create the DB cluster controls configuration elements such as memory, database engine and version, network configuration, security, and maintenance periods.

Before you create a DB cluster and a security group, you must know your DB cluster and network needs. Here are some important things to consider:

- **Resource requirements** – What are the memory and processor requirements for your application or service? You will use these settings when you determine what DB instance class you will use when you create your DB cluster. For specifications about DB instance classes, see [Aurora DB instance classes \(p. 54\)](#).
- **VPC, subnet, and security group** – Your DB cluster will be in a virtual private cloud (VPC). Security group rules must be configured to connect to a DB cluster. The following list describes the rules for each VPC option:
 - **Default VPC** — If your AWS account has a default VPC in the AWS Region, that VPC is configured to support DB clusters. If you specify the default VPC when you create the DB cluster:
 - Make sure to create a *VPC security group* that authorizes connections from the application or service to the Aurora DB cluster. Use the **Security Group** option on the VPC console or the AWS CLI to create VPC security groups. For information, see [Step 4: Create a VPC security group \(p. 1793\)](#).
 - You must specify the default DB subnet group. If this is the first DB cluster you have created in the AWS Region, Amazon RDS will create the default DB subnet group when it creates the DB cluster.
 - **User-defined VPC** — If you want to specify a user-defined VPC when you create a DB cluster:
 - Make sure to create a *VPC security group* that authorizes connections from the application or service to the Aurora DB cluster. Use the **Security Group** option on the VPC console or the AWS CLI to create VPC security groups. For information, see [Step 4: Create a VPC security group \(p. 1793\)](#).
 - The VPC must meet certain requirements in order to host DB clusters, such as having at least two subnets, each in a separate availability zone. For information, see [Amazon Virtual Private Cloud VPCs and Amazon Aurora \(p. 1787\)](#).
 - You must specify a DB subnet group that defines which subnets in that VPC can be used by the DB cluster. For information, see the DB Subnet Group section in [Working with a DB instance in a VPC \(p. 1788\)](#).

- **High availability:** Do you need failover support? On Aurora, a Multi-AZ deployment creates a primary instance and Aurora Replicas. You can configure the primary instance and Aurora Replicas to be in different Availability Zones for failover support. We recommend Multi-AZ deployments for production workloads to maintain high availability. For development and test purposes, you can use a non-Multi-AZ deployment. For more information, see [High availability for Amazon Aurora \(p. 68\)](#).
- **IAM policies:** Does your AWS account have policies that grant the permissions needed to perform Amazon RDS operations? If you are connecting to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see [Identity and access management in Amazon Aurora \(p. 1724\)](#).
- **Open ports:** What TCP/IP port will your database be listening on? The firewall at some companies might block connections to the default port for your database engine. If your company firewall blocks the default port, choose another port for the new DB cluster. Note that once you create a DB cluster that listens on a port you specify, you can change the port by modifying the DB cluster.
- **AWS Region:** What AWS Region do you want your database in? Having the database close in proximity to the application or web service could reduce network latency. For more information, see [Regions and Availability Zones \(p. 11\)](#).

Once you have the information you need to create the security group and the DB cluster, continue to the next step.

Provide access to the DB cluster in the VPC by creating a security group

Your DB cluster will be created in a VPC. Security groups provide access to the DB cluster in the VPC. They act as a firewall for the associated DB cluster, controlling both inbound and outbound traffic at the cluster level. DB clusters are created by default with a firewall and a default security group that prevents access to the DB cluster. You must therefore add rules to a security group that enable you to connect to your DB cluster. Use the network and configuration information you determined in the previous step to create rules to allow access to your DB cluster.

For example, if you have an application that will access a database on your DB cluster in a VPC, you must add a custom TCP rule that specifies the port range and IP addresses that application will use to access the database. If you have an application on an Amazon EC2 cluster, you can use the VPC security group you set up for the Amazon EC2 cluster.

For more information about creating a VPC for use with Aurora, see [How to create a VPC for use with Amazon Aurora \(p. 1793\)](#). For information about common scenarios for accessing a DB instance, see [Scenarios for accessing a DB instance in a VPC \(p. 1800\)](#).

To create a VPC security group

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc>.

Note

Make sure you are in the VPC console, not the RDS console.

2. In the top right corner of the AWS Management Console, choose the AWS Region where you want to create your VPC security group and DB cluster. In the list of Amazon VPC resources for that AWS Region, you should see at least one VPC and several subnets. If you don't, you don't have a default VPC in that AWS Region.
3. In the navigation pane, choose **Security Groups**.
4. Choose **Create security group**.

The **Create security group** page appears.

5. In **Basic details**, enter the **Security group name** and **Description**. For **VPC**, choose the VPC that you want to create your DB cluster in.
6. In **Inbound rules**, choose **Add rule**.
 - a. For **Type**, choose **Custom TCP**.
 - b. For **Port range**, enter the port value to use for your DB cluster.
 - c. For **Source**, choose a security group name or type the IP address range (CIDR value) from where you access the DB cluster. If you choose **My IP**, this allows access to the DB cluster from the IP address detected in your browser.
7. If you need to add more IP addresses or different port ranges, choose **Add rule** and enter the information for the rule.
8. (Optional) In **Outbound rules**, add rules for outbound traffic. By default, all outbound traffic is allowed.
9. Choose **Create security group**.

You can use the VPC security group you just created as the security group for your DB cluster when you create it.

Note

If you use a default VPC, a default subnet group spanning all of the VPC's subnets is created for you. When you create a DB cluster, you can select the default VPC and use **default** for **DB Subnet Group**.

Once you have completed the setup requirements, you can create a DB cluster using your requirements and security group by following the instructions in [Creating an Amazon Aurora DB cluster \(p. 125\)](#). For information about getting started by creating a DB cluster that uses a specific DB engine, see [Getting started with Amazon Aurora \(p. 89\)](#).

Getting started with Amazon Aurora

In this section, you can find out how to create and connect to an Aurora DB cluster using Amazon RDS.

The following procedures are tutorials that demonstrate the basics of getting started with Aurora. Later sections introduce more advanced Aurora concepts and procedures, such as the different kinds of endpoints and how to scale Aurora clusters up and down.

Important

Before you can create or connect to a DB cluster, make sure to complete the tasks in [Setting up your environment for Amazon Aurora \(p. 84\)](#).

Topics

- [Creating a DB cluster and connecting to a database on an Aurora MySQL DB cluster \(p. 89\)](#)
- [Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster \(p. 96\)](#)
- [Tutorial: Create a web server and an Amazon Aurora DB cluster \(p. 103\)](#)

Creating a DB cluster and connecting to a database on an Aurora MySQL DB cluster

The easiest way to create an Aurora MySQL DB cluster is to use the AWS Management Console. After you create the DB cluster, you can use standard MySQL utilities, such as MySQL Workbench, to connect to a database on the DB cluster.

Important

Before you can create or connect to a DB cluster, you must complete the tasks in [Setting up your environment for Amazon Aurora \(p. 84\)](#).

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources that you use. You can delete these resources after you complete the tutorial if they are no longer needed.

Topics

- [Create an Aurora MySQL DB cluster \(p. 89\)](#)
- [Connect to an instance in a DB cluster \(p. 94\)](#)
- [Delete the sample DB cluster, DB subnet group, and VPC \(p. 96\)](#)

Create an Aurora MySQL DB cluster

Before you create a DB cluster, you must first have a virtual private cloud (VPC) based on the Amazon VPC service and an Amazon RDS DB subnet group. Your VPC must have at least one subnet in each of at least two Availability Zones. You can use the default VPC for your AWS account, or you can create your own VPC. The Amazon RDS console is designed to make it easy for you to create your own VPC for use with Amazon Aurora or use an existing VPC with your Aurora DB cluster.

In some cases, you might want to create a VPC and DB subnet group for use with your Aurora DB cluster yourself, rather than having Amazon RDS create them. If so, follow the instructions in [How to create a](#)

[VPC for use with Amazon Aurora \(p. 1793\)](#). Otherwise, follow the instructions in this topic to create your DB cluster and have Amazon RDS create a VPC and DB subnet group for you.

You can use **Easy create** to create an Aurora MySQL-Compatible Edition DB cluster with the RDS console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. When you use **Standard create** instead of **Easy create**, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

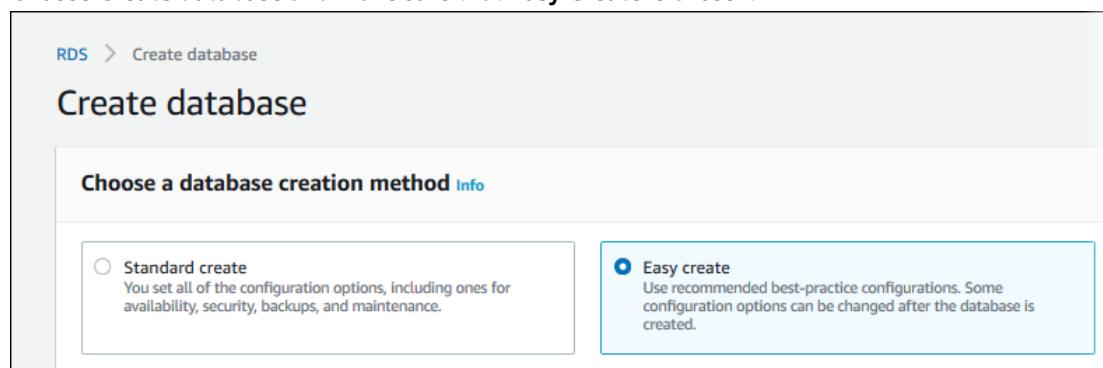

In this tutorial, you use **Easy create** to create an Aurora MySQL-Compatible Edition DB cluster.

Note

For information about creating DB clusters with **Standard create**, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

To create an Aurora MySQL DB cluster with Easy create enabled

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
 2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB cluster.
- Aurora is not available in all AWS Regions. For a list of AWS Regions where Aurora is available, see [Region availability \(p. 12\)](#).
3. In the navigation pane, choose **Databases**.
 4. Choose **Create database** and make sure that **Easy Create** is chosen.

5. For **Engine type**, choose **Amazon Aurora**.
6. For **Edition**, choose **Amazon Aurora with MySQL compatibility**.
7. For **DB instance size**, choose **Dev/Test**.
8. For **DB cluster identifier**, enter a name for the DB cluster, or leave the default name.
9. For **Master username**, enter a name for the user, or leave the default name.

The **Create database** page should look similar to the following image.

Create database

Choose a database creation method [Info](#)

Standard create

You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create

Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

Configuration

Engine type [Info](#)

Amazon Aurora

MySQL

MariaDB

PostgreSQL

Oracle

Microsoft SQL Server

Edition

Amazon Aurora with MySQL compatibility

Amazon Aurora with PostgreSQL compatibility

DB instance size

Production

db.r6g.2xlarge
8 vCPUs
64 GiB RAM

Dev/Test

db.r6g.large
2 vCPUs
16 GiB RAM

DB cluster identifier

Type a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

database-1

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

10. To use an automatically generated password for the DB cluster, make sure that the **Auto generate a password** box is selected.

To enter your password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

11. (Optional) Open **View default settings for Easy create**.

View default settings for Easy create		
Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use Standard Create .		
Configuration	Value	Editable after database is created
Database Features	provisioned	No
Encryption	Enabled	No
VPC	Default VPC (vpc-6594f31c)	No
Option Group	default:aurora-mysql-5-7	No
Subnet Group	default	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-68184619	Yes
Publically Accessible	No	Yes
Database Port	3306	Yes
DB Cluster Identifier	database-1	Yes
DB Instance Identifier	database-1	Yes
DB Engine Version	5.7.mysql_aurora.2.09.2	Yes
DB Parameter Group	default.aurora-mysql5.7	Yes
DB Cluster Parameter Group	default.aurora-mysql5.7	Yes
Performance Insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto Minor Version Upgrade Enabled	Yes
Delete Protection	Not Enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.

- To change settings with **No** in that column, use **Standard create**.
- To change settings with **Yes** in that column, either use **Standard create**, or modify the DB cluster after it is created to change the settings.

The following are important considerations for changing the default settings:

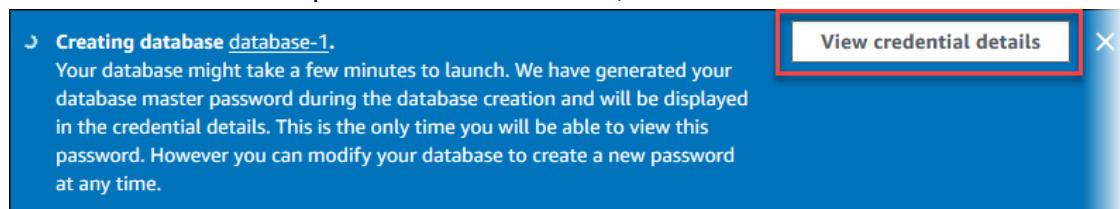

- If you want the DB cluster to use a specific VPC, subnet group, and security group, use **Standard create** to specify these resources. You might have created these resources when you were setting up for Amazon RDS. For more information, see [Setting up your environment for Amazon Aurora \(p. 84\)](#).
- If you want to be able to access the DB cluster from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

If the DB cluster should be private, leave **Public access** set to **No**.

12. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the user name and password for the DB cluster, choose **View credential details**.

To connect to the DB cluster as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB cluster is available, you can modify the DB cluster to do so. For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

13. For **Databases**, choose the name of the new Aurora MySQL DB cluster.

On the RDS console, the details for new DB cluster appear. The DB cluster and its DB instance have a status of **Creating** until the DB cluster is ready to use. When the state changes to **Available** for both, you can connect to the DB cluster. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB cluster is available.

Databases						
		Role	Engine	Region & AZ	Size	Status
<input type="checkbox"/>	<input type="checkbox"/>	DB identifier				Creating
<input type="checkbox"/>	<input type="checkbox"/>	database-1	Regional cluster	Aurora MySQL	us-east-2	1 instance
<input type="checkbox"/>	<input type="checkbox"/>	database-1-instance-1	Reader instance	Aurora MySQL	-	db.r6g.large

Connect to an instance in a DB cluster

After Amazon RDS provisions your DB cluster and creates the primary instance, you can use any standard SQL client application to connect to a database on the DB cluster. In the following procedure, you connect to a database on the Aurora MySQL DB cluster using MySQL monitor commands.

To connect to a database on an Aurora MySQL DB cluster using the MySQL monitor

1. Install a SQL client that you can use to connect to the DB instance.

You can connect to an Aurora MySQL DB cluster by using tools like the MySQL command line utility. For more information on using the MySQL client, see [mysql - the MySQL command-line client](#) in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, see the [Download MySQL Workbench](#) page.

For more information on using MySQL, see the [MySQL documentation](#). For information about installing MySQL (including the MySQL client), see [Installing and upgrading MySQL](#).

If your DB instance is publicly accessible, you can install the SQL client outside of the VPC. If your DB instance is private, you typically install the SQL client on a resource inside the VPC, such as an Amazon EC2 instance.

2. Make sure that your DB cluster is associated with a security group that provides access to it. For more information, see [Setting up your environment for Amazon Aurora \(p. 84\)](#).

If you didn't specify the appropriate security group when you created the DB cluster, you can modify the DB cluster to change its security group. For more information, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

3. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
4. Choose **Databases** and then choose the DB cluster name to show its details. On the **Connectivity & security** tab, copy the value for the **Endpoint name** of the **Writer instance** endpoint. Also, note the port number for the endpoint.

The screenshot shows the AWS RDS console for a database named 'database-1'. At the top, there are 'Modify' and 'Actions' buttons. Below that is a 'Related' section with a search bar. The main area displays a table of database instances:

DB identifier	Role	Engine	Region & AZ	Size
database-1	Regional cluster	Aurora MySQL	us-east-2	1 instance
database-1-instance-1	Writer instance	Aurora MySQL	us-east-2b	db.r6g.large

Below the table are tabs for Connectivity & security, Monitoring, Logs & events, Configuration, Maintenance & backups, and Tags. The 'Connectivity & security' tab is selected.

In the 'Endpoints' section, there are two entries:

Endpoint name	Status	Type	Port
database-1.cluster-ro-...us-east-2.rds.amazonaws.com	Available	Reader instance	3306
database-1.cluster-...us-east-2.rds.amazonaws.com	Available	Writer instance	3306

The second endpoint is circled in red, and the 'Writer instance' label is also circled in red.

- Enter the following command at a command prompt on a client computer to connect to a database on an Aurora MySQL DB cluster using the MySQL monitor. Use the cluster endpoint to connect to the primary instance, and the master user name that you created previously. (You are prompted for a password.) If you supplied a port value other than 3306, use that for the `-P` parameter instead.

```
PROMPT> mysql -h <cluster endpoint> -P 3306 -u <myusername> -p
```

You should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 350
Server version: 5.6.10-log MySQL Community Server (GPL)

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

For more information about connecting to the DB cluster, see [Connecting to an Amazon Aurora MySQL DB cluster \(p. 281\)](#). If you can't connect to your DB cluster, see [Can't connect to Amazon RDS DB instance \(p. 1814\)](#).

Delete the sample DB cluster, DB subnet group, and VPC

After you have connected to the sample DB cluster that you created, you can delete the DB cluster, DB subnet group, and VPC (if you created a VPC).

To delete a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases** and then choose the DB instance associated with the DB cluster.
3. For **Actions**, choose **Delete**.
4. Choose **Delete**.

After all of the DB instances associated with a DB cluster are deleted, the DB cluster is deleted automatically.

To delete a DB subnet group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Subnet groups** and then choose the DB subnet group.
3. Choose **Delete**.
4. Choose **Delete**.

To delete a VPC

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **Your VPCs** and then choose the VPC that was created for this procedure.
3. For **Actions**, choose **Delete VPC**.
4. Choose **Delete**.

Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster

The easiest way to create an Aurora PostgreSQL DB cluster is to use the Amazon RDS console. After you create the DB cluster, you can use standard PostgreSQL utilities, such as pgAdmin, to connect to a database on the DB cluster.

Important

Before you can create or connect to a DB cluster, you must complete the tasks in [Setting up your environment for Amazon Aurora \(p. 84\)](#).

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources that you use. You can delete these resources after you complete the tutorial if they are no longer needed.

Topics

- [Create an Aurora PostgreSQL DB cluster \(p. 97\)](#)
- [Connect to an instance in an Aurora PostgreSQL DB cluster \(p. 101\)](#)
- [Delete the sample DB cluster, DB subnet group, and VPC \(p. 102\)](#)

Create an Aurora PostgreSQL DB cluster

Before you create a DB cluster, make sure first to have a virtual private cloud (VPC) based on the Amazon VPC service and an Amazon RDS DB subnet group. Your VPC must have at least one subnet in each of at least two Availability Zones. You can use the default VPC for your AWS account, or you can create your own VPC. The Amazon RDS console is designed to make it easy for you to create your own VPC for use with Amazon Aurora or use an existing VPC with your Aurora DB cluster.

In some cases, you might want to create a VPC and DB subnet group for use with your Amazon Aurora DB cluster yourself, rather than having Amazon RDS create them. If so, follow the instructions in [How to create a VPC for use with Amazon Aurora \(p. 1793\)](#). Otherwise, follow the instructions in this topic to create your DB cluster and have Amazon RDS create a VPC and DB subnet group for you.

You can use **Easy create** to create an Aurora PostgreSQL DB cluster with the AWS Management Console. With **Easy create**, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for the other configuration options. When you use **Standard create** instead of **Easy create**, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

In this example, you use **Easy create** to create an Aurora PostgreSQL DB cluster.

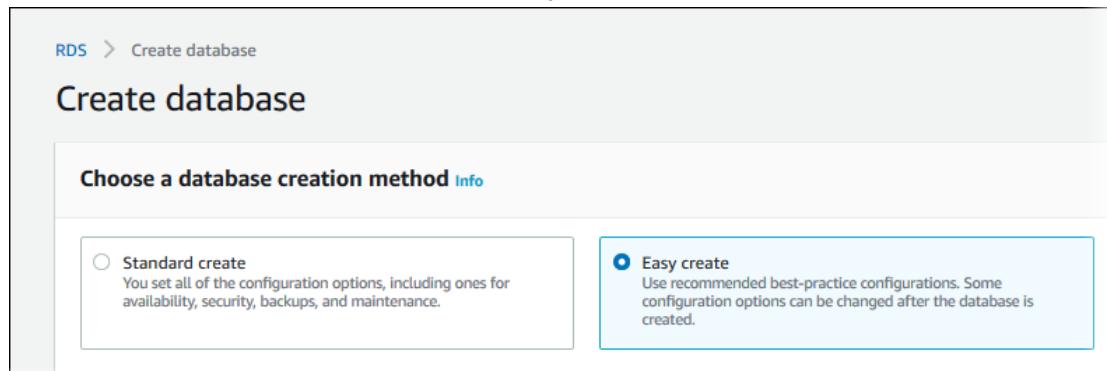

Note

For information about creating DB clusters with **Standard create**, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

To create an Aurora PostgreSQL DB cluster with Easy create enabled

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB cluster.

Aurora is not available in all AWS Regions. For a list of AWS Regions where Aurora is available, see [Region availability \(p. 12\)](#).
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy Create** is chosen.

5. For **Engine type**, choose **Amazon Aurora**.
6. For **Edition**, choose **Amazon Aurora with PostgreSQL compatibility**.

7. For **DB instance size**, choose **Dev/Test**.
8. For **DB cluster identifier**, enter a name for the DB cluster, or leave the default name.
9. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.

Create database

Choose a database creation method [Info](#)

Standard create
You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create
Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

Configuration

Engine type [Info](#)

Amazon Aurora 

MySQL 

MariaDB 

PostgreSQL 

Microsoft SQL Server 

Edition

Amazon Aurora with MySQL compatibility

Amazon Aurora with PostgreSQL compatibility

DB instance size

Production
db.r6g.2xlarge
8 vCPUs
64 GiB RAM

Dev/Test
db.r6g.large
2 vCPUs
16 GiB RAM

DB cluster identifier

Type a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

database-1

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

10. To use an automatically generated master password for the DB cluster, make sure that the **Auto generate a password** box is selected.

To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

11. (Optional) Open **View default settings for Easy create**.

View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use [Standard Create](#).

Configuration	Value	Editable after database is created
Database Features	provisioned	No
Encryption	Enabled	No
VPC	tutorial-vpc (vpc-057ab62a5117ac9fb)	No
Option Group	default:aurora-postgresql-11	No
Subnet Group	tutorial-db-subnet-group	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-0d3bc58e3febca979	Yes
Publicly Accessible	No	Yes
Database Port	5432	Yes
DB Cluster Identifier	database-1	Yes
DB Instance Identifier	database-1	Yes
DB Engine Version	11.9	Yes
DB Parameter Group	default.aurora-postgresql11	Yes
DB Cluster Parameter Group	default.aurora-postgresql11	Yes
Performance Insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto Minor Version Upgrade Enabled	Yes
Delete Protection	Not Enabled	Yes

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.

- To change settings with **No** in that column, use **Standard create**.
- To change settings with **Yes** in that column, either use **Standard create**, or modify the DB cluster after it is created to change the settings.

The following are important considerations for changing the default settings:

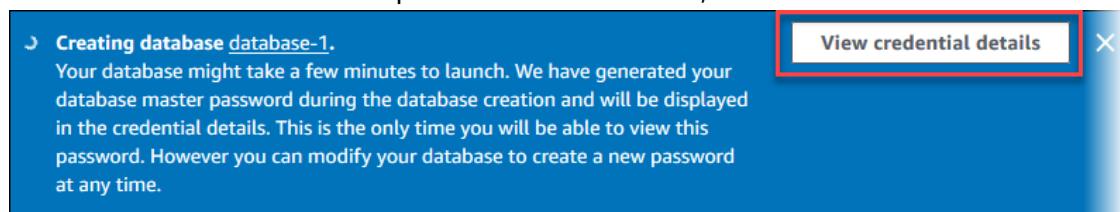

- If you want the DB cluster to use a specific VPC, subnet group, and security group, use **Standard create** to specify these resources. You might have created these resources when you were setting up for Amazon RDS. For more information, see [Setting up your environment for Amazon Aurora \(p. 84\)](#).
- If you want to be able to access the DB cluster from a client outside of its VPC, use **Standard create** to set **Public access** to **Yes**.

If the DB cluster should be private, leave **Public access** set to **No**.

12. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB cluster, choose **View credential details**.

To connect to the DB cluster as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB cluster is available, you can modify the DB cluster to do so. For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

13. For **Databases**, choose the name of the new Aurora PostgreSQL DB cluster.

On the RDS console, the details for new DB cluster appear. The DB cluster and its DB instance have a status of **Creating** until the DB cluster is ready to use. When the state changes to **Available** for both, you can connect to the DB cluster. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB cluster is available.

Databases						
	DB identifier	Role	Engine	Region & AZ	Size	Status
Filter databases						
<input type="checkbox"/>	database-1	Regional cluster	Aurora PostgreSQL	us-west-1	1 instance	Creating
<input type="checkbox"/>	database-1-instance-1	Reader instance	Aurora PostgreSQL	-	db.r6g.large	Creating

Connect to an instance in an Aurora PostgreSQL DB cluster

After Amazon RDS provisions your DB cluster and creates the primary instance, you can use any standard SQL client application to connect to a database on the DB cluster.

To connect to a database on an Aurora PostgreSQL DB cluster

1. Make sure that your DB cluster is associated with a security group that provides access to it. For more information, see [Setting up your environment for Amazon Aurora \(p. 84\)](#).

If you didn't specify the appropriate security group when you created the DB cluster, you can modify the DB cluster to change its security group. For more information, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

2. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
3. Choose **Databases** and then choose the DB cluster name to show its details. On the **Connectivity & security** tab, copy the value for the **Endpoint name** of the **Writer instance** endpoint. Also, note the port number for the endpoint.

The screenshot shows the AWS RDS Databases page for a cluster named "database-1". The "Connectivity & security" tab is selected. In the "Endpoints" section, there are two entries:

Endpoint name	Status	Type	Port
database-1.cluster-ro-*.us-west-1.rds.amazonaws.com	Available	Reader instance	5432
database-1.cluster-*.us-west-1.rds.amazonaws.com	Available	Writer instance	5432

The "Writer instance" endpoint is circled in red.

4. If your client computer has PostgreSQL installed, you can use a local instance of psql to connect to a PostgreSQL DB instance. To connect to your PostgreSQL DB instance using psql, provide host information and access credentials.

The following format is used to connect to a PostgreSQL DB instance on Amazon RDS.

```
psql --host=DB_instance_endpoint --port=port --username=master_user_name --password --dbname=database_name
```

For example, the following command connects to a database called mypgdb on a PostgreSQL DB instance called mypostgresql using fictitious credentials.

```
psql --host=database-1.123456789012.us-west-1.rds.amazonaws.com --port=5432 --username=awsuser --password --dbname=postgres
```

For more information about connecting to the DB cluster using the endpoint and port, see [Connecting to an Amazon Aurora PostgreSQL DB cluster \(p. 285\)](#). If you can't connect to your DB cluster, see [Can't connect to Amazon RDS DB instance \(p. 1814\)](#).

Delete the sample DB cluster, DB subnet group, and VPC

After you have connected to the sample DB cluster that you created, you can delete the DB cluster, DB subnet group, and VPC (if you created a VPC).

To delete a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases** and then choose the DB instance associated with the DB cluster.
3. For **Actions**, choose **Delete**.
4. Choose **Delete**.

After all of the DB instances associated with a DB cluster are deleted, the DB cluster is deleted automatically.

To delete a DB subnet group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Subnet groups** and then choose the DB subnet group.
3. Choose **Delete**.
4. Choose **Delete**.

To delete a VPC

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **Your VPCs** and then choose the VPC that was created for this procedure.
3. For **Actions**, choose **Delete VPC**.
4. Choose **Delete**.

Tutorial: Create a web server and an Amazon Aurora DB cluster

This tutorial helps you install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is an Aurora MySQL DB cluster. Both the Amazon EC2 instance and the DB cluster run in a virtual private cloud (VPC) based on the Amazon VPC service.

Important

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

Note

This tutorial works with Amazon Linux and might not work for other versions of Linux such as Ubuntu.

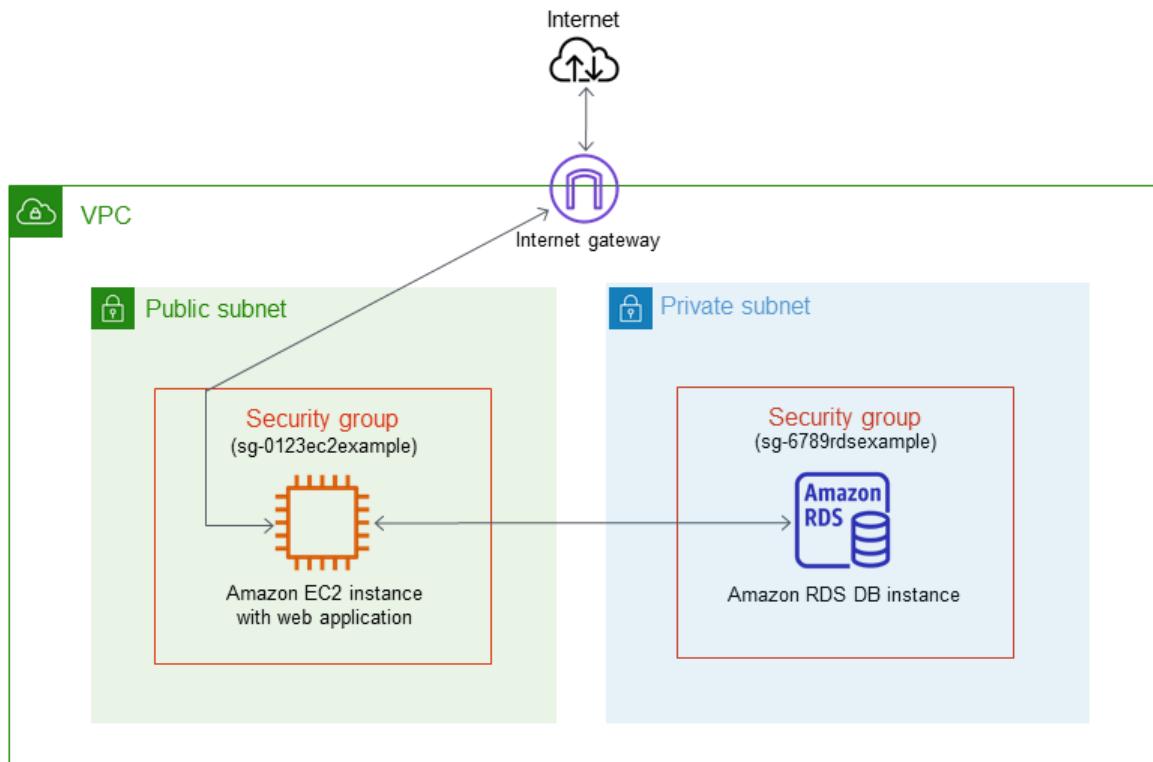

In the tutorial that follows, you specify the VPC, subnets, and security groups when you create the DB cluster. You also specify them when you create the EC2 instance to host your web server. The VPC, subnets, and security groups are required for the DB cluster and the web server to communicate. After the VPC is set up, this tutorial shows you how to create the DB cluster and install the web server. You connect your web server to your DB cluster in the VPC using the DB cluster writer endpoint.

1. Complete the tasks in [Tutorial: Create an Amazon VPC for use with a DB instance \(p. 1805\)](#).

Before you begin this tutorial, make sure that you have a VPC with both public and private subnets, and corresponding security groups. If you don't have these, complete the following tasks in the tutorial:

- a. [Create a VPC with private and public subnets \(p. 1805\)](#)
 - b. [Create additional subnets \(p. 1806\)](#)
 - c. [Create a VPC security group for a public web server \(p. 1807\)](#)
 - d. [Create a VPC security group for a private DB instance \(p. 1808\)](#)
 - e. [Create a DB subnet group \(p. 1808\)](#)
2. [Create an Amazon Aurora DB cluster \(p. 104\)](#)
 3. [Create an EC2 instance and install a web server \(p. 109\)](#)

The following diagram shows the configuration when the tutorial is complete.

Create an Amazon Aurora DB cluster

In this step, you create an Amazon Aurora MySQL DB cluster that maintains the data used by a web application.

Important

Before you begin this step, you must have a VPC with both public and private subnets, and corresponding security groups. If you don't have these, see [Tutorial: Create an Amazon VPC for use with a DB instance \(p. 1805\)](#). Complete the steps in [Create a VPC with private and public subnets \(p. 1805\)](#), [Create additional subnets \(p. 1806\)](#), [Create a VPC security group for a public web server \(p. 1807\)](#), and [Create a VPC security group for a private DB instance \(p. 1808\)](#).

To create an Aurora MySQL DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create the DB cluster. This example uses the US West (Oregon) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, shown following, make sure that the **Standard create** option is chosen, and then choose **Amazon Aurora**. Keep the default values for **Version** and the other engine options.

RDS > Create database

Create database

Choose a database creation method Info

Standard create
You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create
Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

6. In the **Templates** section, choose **Dev/Test**.
7. In the **Settings** section, set these values:
 - **DB cluster identifier** – `tutorial-db-cluster`
 - **Master username** – `tutorial_user`
 - **Auto generate a password** – Disable the option.
 - **Master password** – Choose a password.
 - **Confirm password** – Retype the password.

Settings

DB cluster identifier [Info](#)

Type a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

tutorial-db-cluster

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

▼ Credentials Settings

Master username [Info](#)

Type a login ID for the master user of your DB instance.

tutorial_user

1 to 16 alphanumeric characters. First character must be a letter

Auto generate a password

Amazon RDS can generate a password for you, or you can specify your own password

Master password [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), "(double quote) and @ (at sign).

Confirm password [Info](#)

8. In the **DB instance class** section, enable **Include previous generation classes**, and set these values:
 - **Burstable classes (includes t classes)**
 - **db.t2.small**

DB instance class

DB instance class [Info](#)

Choose a DB instance class that meets your processing power and memory requirements. The DB instance class options below are limited to those supported by the engine you selected above.

Memory optimized classes (includes r classes)

Burstable classes (includes t classes)

db.t2.small

1 vCPUs 2 GiB RAM Not EBS Optimized

i New instance classes are available for specific engine versions. [Info](#)

Include previous generation classes

9. In the **Availability & durability** section, use the default values.
10. In the **Connectivity** section, set these values:

- **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as the `tutorial-vpc` (`vpc-identifier`) created in [Create a VPC with private and public subnets \(p. 1805\)](#)

Note

The VPC must have subnets in different Availability Zones.

- **Subnet group** – The DB subnet group for the VPC, such as the `tutorial-db-subnet-group` created in [Create a DB subnet group \(p. 1808\)](#)

- **Public access** – No

- **VPC security group** – Choose existing

- **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as the `tutorial-db-securitygroup` created in [Create a VPC security group for a private DB instance \(p. 1808\)](#).

Remove other security groups, such as the default security group, by choosing the **X** associated with each.

- **Availability Zone – No preference**

- Open **Additional configuration**, and make sure **Database port** uses the default value **3306**.

Connectivity

Virtual private cloud (VPC) [Info](#)
VPC that defines the virtual networking environment for this DB instance.

tutorial-vpc (vpc-08bf0876fa2e229cf)

Only VPCs with a corresponding DB subnet group are listed.

i After a database is created, you can't change the VPC selection.

Subnet group [Info](#)
DB subnet group that defines which subnets and IP ranges the DB instance can use in the VPC you selected.

▼ Additional configuration

Database port [Info](#)
TCP/IP port that the database will use for application connections.

3306

11. Open the **Additional configuration** section, and enter **sample** for **Initial database name**. Keep the default settings for the other options.
 12. To create your Aurora MySQL DB cluster, choose **Create database**.
- Your new DB cluster appears in the **Databases** list with the status **Creating**.
13. Wait for the **Status** of your new DB cluster to show as **Available**. Then choose the DB cluster name to show its details.
 14. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the writer DB instance.

The screenshot shows the AWS RDS console with the following details:

- Databases > tutorial-db-cluster**
- tutorial-db-cluster** (DB identifier)
- Related** section: A search bar labeled "Filter databases".
- DB identifier** table:

DB identifier	Role	Engine	Region & AZ	Size
tutorial-db-cluster	Regional	Aurora MySQL	us-west-2	1 instance
tutorial-db-cluster-instance-1	Writer	Aurora MySQL	-	db.t2.small
- Endpoints (2)** table:

Endpoint name	Status	Type	Port
tutorial-db-cluster.cluster-ro-*.us-west-2.rds.amazonaws.com	Creating	Reader	3306
tutorial-db-cluster.cluster-*.us-west-2.rds.amazonaws.com	Creating	Writer	3306

 The "Writer" endpoint and its port (3306) are circled in red.

Note the endpoint and port for your writer DB instance. You use this information to connect your web server to your DB cluster.

15. Complete [Create an EC2 instance and install a web server \(p. 109\)](#).

Create an EC2 instance and install a web server

In this step, you create a web server to connect to the Amazon Aurora DB cluster that you created in [Create an Amazon Aurora DB cluster \(p. 104\)](#).

Launch an EC2 instance

First, you create an Amazon EC2 instance in the public subnet of your VPC.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown following.

The screenshot shows the AWS EC2 Resources page. At the top, it displays resource counts: 1 Running instances, 0 Snapshots, 2 Key pairs, 1 Elastic IPs, 0 Volumes, and 0 Security groups. Below this, a callout box says: "Easily size, configure, and deploy Microsoft SQL Server Always On availability groups on AWS". The main section is titled "Launch instance" with the sub-instruction: "To get started, launch an Amazon EC2 instance, which is a virtual server in the cloud." A large red circle highlights the "Launch instance" button. A note below it states: "Note: Your instances will launch in the US West (Oregon) Region". To the right, there are service links for "Server Migration", "Region Selector", "US West (Oregon)", and "Available Regions".

3. Choose the **Amazon Linux 2 AMI**.

The screenshot shows the "Step 1: Choose an Amazon Machine Image (AMI)" screen. It lists three AMIs: "Amazon Linux 2 AMI (HVM), SSD Volume Type", "Red Hat Enterprise Linux 8 (HVM), SSD Volume Type", and "SUSE Linux Enterprise Server 15 SP2 (HVM), SSD Volume Type". The first item is selected and highlighted with a red box. The "Select" button next to it is also highlighted. The "Amazon Linux" row includes a note: "Amazon Linux 2 comes with five years support. It provides Linux kernel 4.14 tuned for optimal performance on Amazon EC2, systemd 219, GCC 7.3, Glibc 2.26, Binutils 2.29.1, and the latest software packages through extras. This AMI is the successor of the Amazon Linux AMI that is approaching end of life on December 31, 2020 and has been removed from this wizard." There are also checkboxes for "Root device type: ebs", "Virtualization type: hvm", and "ENAs Enabled: Yes".

4. Choose the **t2.micro** instance type, as shown following, and then choose **Next: Configure Instance Details**.

Step 2: Choose an Instance Type

Amazon EC2 provides a wide selection of instance types optimized to fit different use cases. Instances are virtual servers that can run applications. They have varying combinations of CPU, memory, storage, and networking capacity, and give you the flexibility to choose the appropriate mix of resources for your applications. [Learn more](#) about instance types and how they can meet your computing needs.

Filter by: All instance families Current generation Show/Hide Columns								
Currently selected: t2.micro (- ECUs, 1 vCPUs, 2.5 GHz, -, 1 GiB memory, EBS only)								
	Family	Type	vCPUs	Memory (GiB)	Instance Storage (GB)	EBS-Optimized Available	Network Performance	IPv6 Support
<input type="checkbox"/>	t2	t2.nano	1	0.5	EBS only	-	Low to Moderate	Yes
<input checked="" type="checkbox"/>	t2	t2.micro <small>Free tier eligible</small>	1	1	EBS only	-	Low to Moderate	Yes
<input type="checkbox"/>	t2	t2.small	1	2	EBS only	-	Low to Moderate	Yes
<input type="checkbox"/>	t2	t2.medium	2	4	EBS only	-	Low to Moderate	Yes
<input type="checkbox"/>	t2	t2.large	2	8	EBS only	-	Low to Moderate	Yes

[Cancel](#) [Previous](#) [Review and Launch](#) [Next: Configure Instance Details](#)

5. On the **Configure Instance Details** page, shown following, set these values and keep the other values as their defaults:

- **Network:** Choose the VPC with both public and private subnets that you chose for the DB cluster, such as the `vpc-identifier` | `tutorial-vpc` created in [Create a VPC with private and public subnets \(p. 1805\)](#).
- **Subnet:** Choose an existing public subnet, such as `subnet-identifier` | `Tutorial public` | `us-west-2a` created in [Create a VPC security group for a public web server \(p. 1807\)](#).
- **Auto-assign Public IP:** Choose **Enable**.

Step 3: Configure Instance Details

Configure the instance to suit your requirements. You can launch multiple instances from the same AMI, request Spot instances to take advantage of the lower pricing, assign an access management role to the instance, and more.

Number of instances	<input type="text" value="1"/>	Launch into Auto Scaling Group
Purchasing option	<input type="checkbox"/> Request Spot instances	
Network	vpc-<i>identifier</i> tutorial-vpc Create new VPC Subnet Create new subnet 249 IP Addresses available	
Auto-assign Public IP	Enable	
Placement group	<input type="checkbox"/> Add instance to placement group	
Capacity Reservation	Open	
Domain join directory	No directory Create new directory	
IAM role	None Create new IAM role	
CPU options	<input type="checkbox"/> Specify CPU options	
Shutdown behavior	Stop	
Stop - Hibernate behavior	<input type="checkbox"/> Enable hibernation as an additional stop behavior	
Enable termination protection	<input type="checkbox"/> Protect against accidental termination	
Monitoring	<input type="checkbox"/> Enable CloudWatch detailed monitoring <small>Additional charges apply.</small>	
Tenancy	Shared - Run a shared hardware instance <small>Additional charges will apply for dedicated tenancy.</small>	
Elastic Inference	<input type="checkbox"/> Add an Elastic Inference accelerator	

[Cancel](#) [Previous](#) [Review and Launch](#) [Next: Add Storage](#)

6. Choose **Next: Add Storage**.
7. On the **Add Storage** page, keep the default values and choose **Next: Add Tags**.
8. On the **Add Tags** page, shown following, choose **Add Tag**, then enter **Name** for **Key** and enter **tutorial-web-server** for **Value**.

Step 5: Add Tags

A tag consists of a case-sensitive key-value pair. For example, you could define a tag with key = Name and value = Webserver. A copy of a tag can be applied to volumes, instances or both. Tags will be applied to all instances and volumes. [Learn more](#) about tagging your Amazon EC2 resources.

Key (127 characters maximum)	Value (255 characters maximum)	Instances <small>(1)</small>	Volumes <small>(1)</small>
<input type="text" value="Name"/>	<input type="text" value="tutorial-web-server"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
Add another tag (Up to 50 tags maximum)		Cancel Previous Review and Launch Next: Configure Security Group	

9. Choose **Next: Configure Security Group**.
10. On the **Configure Security Group** page, shown following, choose **Select an existing security group**. Then choose an existing security group, such as the **tutorial-securitygroup** created in [Create a VPC security group for a public web server \(p. 1807\)](#). Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.

Step 6: Configure Security Group

A security group is a set of firewall rules that control the traffic for your instance. On this page, you can add rules to allow specific traffic to reach your instance. For example, if you want to set up a web server and allow Internet traffic to reach your instance, add rules that allow unrestricted access to the HTTP and HTTPS ports. You can create a new security group or select from an existing one below. [Learn more](#) about Amazon EC2 security groups.

Assign a security group: Create a new security group Select an existing security group

Security Group ID	Name	Description	Actions
sg-0ef508f81f84a5764	default	default VPC security group	Copy to new
sg-0ef508f81f84a5764	tutorial-db-securitygroup	Tutorial DB Instance Security Group	Copy to new
sg-0ef508f81f84a5764	tutorial-securitygroup	Tutorial Security Group	Copy to new

Inbound rules for sg-0ef508f81f84a5764 (Selected security groups: sg-0ef508f81f84a5764)

Type	Protocol	Port Range	Source	Description
HTTP	TCP	80	<input type="text" value="0.0.0.0/0"/>	
SSH	TCP	22	<input type="text" value="0.0.0.0/0"/>	

Cancel **Previous** **Review and Launch**

11. Choose **Review and Launch**.
12. On the **Review Instance Launch** page, shown following, verify your settings and then choose **Launch**.

Step 7: Review Instance Launch

The screenshot shows the 'Step 7: Review Instance Launch' page for creating a Lambda function. At the top, it displays the selected AMI: 'Amazon Linux 2 AMI (HVM), SSD Volume Type - ami-0cf6f5c8a62fa5da6'. A note indicates it's a 'Free tier eligible' instance. Below this, there's a brief description of the Amazon Linux 2 AMI and its compatibility with EC2. The 'Root Device Type: ebs' and 'Virtualization type: hvm' are also listed.

Instance Type:

Instance Type	ECUs	vCPUs	Memory (GiB)	Instance Storage (GB)	EBS-Optimized Available	Network Performance
t2.micro	-	1	1	EBS only	-	Low to Moderate

Security Groups:

Security Group ID	Name	Description
sg-...	tutorial-securitygroup	Tutorial Security Group

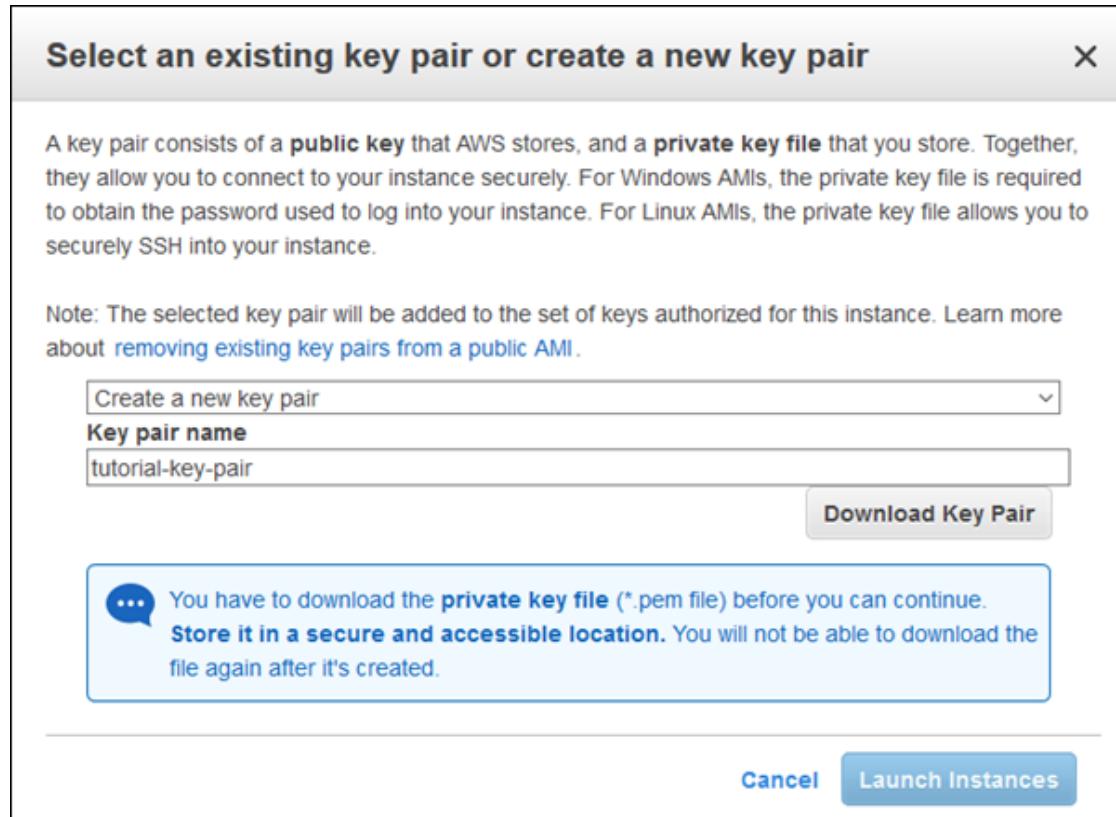

All selected security groups inbound rules:

Type	Protocol	Port Range	Source	Description
HTTP	TCP	80	...	
SSH	TCP	22	...	

Instance Details:

Cancel Previous Launch

- On the **Select an existing key pair or create a new key pair** page, shown following, choose **Create a new key pair** and set **Key pair name** to `tutorial-key-pair`. Choose **Download Key Pair**, and then save the key pair file on your local machine. You use this key pair file to connect to your EC2 instance.

14. To launch your EC2 instance, choose **Launch Instances**. On the **Launch Status** page, shown following, note the identifier for your new EC2 instance, for example: i-0288d65fd4470b6a9.

Launch Status

Your instances are now launching
The following instance launches have been initiated: [i-0288d65fd4470b6a9](#) [View launch log](#)

Get notified of estimated charges
Create [billing alerts](#) to get an email notification when estimated charges on your AWS bill exceed an amount you define (for example, if you exceed the free usage tier).

How to connect to your instances

Your instances are launching, and it may take a few minutes until they are in the **running** state, when they will be ready for you to use. Usage hours on your new instances will start immediately and continue to accrue until you stop or terminate your instances.

Click [View Instances](#) to monitor your instances' status. Once your instances are in the **running** state, you can [connect](#) to them from the Instances screen. [Find out](#) how to connect to your instances.

▼ Here are some helpful resources to get you started

- [How to connect to your Linux instance](#)
- [Learn about AWS Free Usage Tier](#)
- [Amazon EC2: User Guide](#)
- [Amazon EC2: Discussion Forum](#)

While your instances are launching you can also

- [Create status check alarms](#) to be notified when these instances fail status checks. (Additional charges may apply)
- [Create and attach additional EBS volumes](#) (Additional charges may apply)
- [Manage security groups](#)

[View Instances](#)

15. Choose [View Instances](#) to find your instance.
16. Wait until **Instance Status** for your instance reads as **Running** before continuing.

Install an Apache web server with PHP

Next, you connect to your EC2 instance and install the web server.

To connect to your EC2 instance and install the Apache web server with PHP

1. Connect to the EC2 instance that you created earlier by following the steps in [Connect to your Linux instance](#).
2. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

Note

The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

```
sudo yum update -y
```

3. After the updates complete, install the PHP software using the `amazon-linux-extras install` command. This command installs multiple software packages and related dependencies at the same time.

```
sudo amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2
```

If you receive an error stating `sudo: amazon-linux-extras: command not found`, then your instance was not launched with an Amazon Linux 2 AMI (perhaps you are using the Amazon Linux AMI instead). You can view your version of Amazon Linux using the following command.

```
cat /etc/system-release
```

For more information, see [Updating instance software](#).

4. Install the Apache web server.

```
sudo yum install -y httpd
```

5. Start the web server with the command shown following.

```
sudo systemctl start httpd
```

You can test that your web server is properly installed and started. To do this, enter the public Domain Name System (DNS) name of your EC2 instance in the address bar of a web browser, for example: `http://ec2-42-8-168-21.us-west-1.compute.amazonaws.com`. If your web server is running, then you see the Apache test page.

If you don't see the Apache test page, check your inbound rules for the VPC security group that you created in [Tutorial: Create an Amazon VPC for use with a DB instance \(p. 1805\)](#). Make sure that your inbound rules include a rule allowing HTTP (port 80) access for the IP address you use to connect to the web server.

Note

The Apache test page appears only when there is no content in the document root directory, `/var/www/html`. After you add content to the document root directory, your content appears at the public DNS address of your EC2 instance instead of the Apache test page.

6. Configure the web server to start with each system boot using the `systemctl` command.

```
sudo systemctl enable httpd
```

To allow `ec2-user` to manage files in the default root directory for your Apache web server, modify the ownership and permissions of the `/var/www` directory. There are many ways to accomplish this task. In this tutorial, you add `ec2-user` to the `apache` group, to give the `apache` group ownership of the `/var/www` directory and assign write permissions to the group.

To set file permissions for the Apache web server

1. Add the `ec2-user` user to the `apache` group.

```
sudo usermod -a -G apache ec2-user
```

2. Log out to refresh your permissions and include the new `apache` group.

```
exit
```

3. Log back in again and verify that the `apache` group exists with the `groups` command.

```
groups
```

Your output looks similar to the following:

```
ec2-user adm wheel apache systemd-journal
```

4. Change the group ownership of the /var/www directory and its contents to the apache group.

```
sudo chown -R ec2-user:apache /var/www
```

5. Change the directory permissions of /var/www and its subdirectories to add group write permissions and set the group ID on subdirectories created in the future.

```
sudo chmod 2775 /var/www
find /var/www -type d -exec sudo chmod 2775 {} \;
```

6. Recursively change the permissions for files in the /var/www directory and its subdirectories to add group write permissions.

```
find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, `ec2-user` (and any future members of the `apache` group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

Note

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of web pages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption. For more information, see [Tutorial: Configure SSL/TLS with the Amazon Linux AMI](#) in the *Amazon EC2 User Guide*.

Connect your Apache web server to your DB instance

Next, you add content to your Apache web server that connects to your Amazon Aurora DB cluster.

To add content to the Apache web server that connects to your DB cluster

1. While still connected to your EC2 instance, change the directory to /var/www and create a new subdirectory named `inc`.

```
cd /var/www
mkdir inc
cd inc
```

2. Create a new file in the `inc` directory named `dbinfo.inc`, and then edit the file by calling `nano` (or the editor of your choice).

```
>dbinfo.inc
nano dbinfo.inc
```

3. Add the following contents to the `dbinfo.inc` file. Here, `db_instance_endpoint` is DB cluster writer endpoint, without the port, and `master_password` is the master password for your DB cluster.

Note

We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.

```
<?php

define('DB_SERVER', 'db_cluster_writer_endpoint');
define('DB_USERNAME', 'tutorial_user');
define('DB_PASSWORD', 'master password');
define('DB_DATABASE', 'sample');

?>
```

4. Save and close the dbinfo.inc file.
5. Change the directory to /var/www/html.

```
cd /var/www/html
```

6. Create a new file in the html directory named SamplePage.php, and then edit the file by calling nano (or the editor of your choice).

```
>SamplePage.php
nano SamplePage.php
```

7. Add the following contents to the SamplePage.php file:

Note

We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.

```
<?php include "../inc/dbinfo.inc"; ?>
<html>
<body>
<h1>Sample page</h1>
<?php

/* Connect to MySQL and select the database. */
$connection = mysqli_connect(DB_SERVER, DB_USERNAME, DB_PASSWORD);

if (mysqli_connect_errno()) echo "Failed to connect to MySQL: " .
mysqli_connect_error();

$database = mysqli_select_db($connection, DB_DATABASE);

/* Ensure that the EMPLOYEES table exists. */
VerifyEmployeesTable($connection, DB_DATABASE);

/* If input fields are populated, add a row to the EMPLOYEES table. */
$employee_name = htmlentities($_POST['NAME']);
$employee_address = htmlentities($_POST['ADDRESS']);

if (strlen($employee_name) || strlen($employee_address)) {
    AddEmployee($connection, $employee_name, $employee_address);
}
?>
```

```

<!-- Input form -->
<form action="<?PHP echo $_SERVER['SCRIPT_NAME'] ?>" method="POST">
  <table border="0">
    <tr>
      <td>NAME</td>
      <td>ADDRESS</td>
    </tr>
    <tr>
      <td>
        <input type="text" name="NAME" maxlength="45" size="30" />
      </td>
      <td>
        <input type="text" name="ADDRESS" maxlength="90" size="60" />
      </td>
      <td>
        <input type="submit" value="Add Data" />
      </td>
    </tr>
  </table>
</form>

<!-- Display table data. -->
<table border="1" cellpadding="2" cellspacing="2">
  <tr>
    <td>ID</td>
    <td>NAME</td>
    <td>ADDRESS</td>
  </tr>
<?php

$result = mysqli_query($connection, "SELECT * FROM EMPLOYEES");

while($query_data = mysqli_fetch_row($result)) {
  echo "<tr>";
  echo "<td>",$query_data[0], "</td>",
        "<td>",$query_data[1], "</td>",
        "<td>",$query_data[2], "</td>";
  echo "</tr>";
}
?>

</table>

<!-- Clean up. -->
<?php

mysqli_free_result($result);
mysqli_close($connection);

?>

</body>
</html>

<?php

/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
  $n = mysqli_real_escape_string($connection, $name);
  $a = mysqli_real_escape_string($connection, $address);

  $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');";

  if(!mysqli_query($connection, $query)) echo("<p>Error adding employee data.</p>");
```

```
}

/* Check whether the table exists and, if not, create it. */
function VerifyEmployeesTable($connection, $dbName) {
    if(!TableExists("EMPLOYEES", $connection, $dbName))
    {
        $query = "CREATE TABLE EMPLOYEES (
            ID int(11) UNSIGNED AUTO_INCREMENT PRIMARY KEY,
            NAME VARCHAR(45),
            ADDRESS VARCHAR(90)
        )";

        if(!mysqli_query($connection, $query)) echo("<p>Error creating table.</p>");
    }
}

/* Check for the existence of a table. */
function TableExists($tableName, $connection, $dbName) {
    $t = mysqli_real_escape_string($connection, $tableName);
    $d = mysqli_real_escape_string($connection, $dbName);

    $checktable = mysqli_query($connection,
        "SELECT TABLE_NAME FROM information_schema.TABLES WHERE TABLE_NAME = '$t' AND
        TABLE_SCHEMA = '$d'");
    if(mysqli_num_rows($checktable) > 0) return true;
    return false;
}
?>
```

8. Save and close the SamplePage.php file.
9. Verify that your web server successfully connects to your DB cluster by opening a web browser and browsing to <http://EC2 instance endpoint/SamplePage.php>, for example: <http://ec2-55-122-41-31.us-west-2.compute.amazonaws.com/SamplePage.php>.

You can use SamplePage.php to add data to your DB cluster. The data that you add is then displayed on the page. To verify that the data was inserted into the table, you can install MySQL on the Amazon EC2 instance, connect to the DB instance, and query the table.

For information about connecting to a DB cluster, see [Connecting to an Amazon Aurora DB cluster \(p. 281\)](#).

To make sure that your DB cluster is as secure as possible, verify that sources outside of the VPC can't connect to your DB cluster.

After you have finished testing your web server and your database, you should delete your DB cluster and your Amazon EC2 instance.

- To delete a DB cluster, follow the instructions in [Deleting Aurora DB clusters and DB instances \(p. 467\)](#). You don't need to create a final snapshot.
- To terminate an Amazon EC2 instance, follow the instruction in [Terminate your instance](#) in the *Amazon EC2 User Guide*.

Amazon Aurora tutorials and sample code

The AWS documentation includes several tutorials that guide you through common Amazon Aurora use cases. Many of these tutorials show you how to use Amazon Aurora with other AWS services. In addition, you can access sample code in GitHub.

Note

You can find more tutorials at the [AWS Database Blog](#). For information about training, see [AWS Training and Certification](#).

Configuring your Amazon Aurora DB cluster

This section shows how to set up your Aurora DB cluster. Before creating an Aurora DB cluster, decide on the DB instance class that will run the DB cluster. Also, decide where the DB cluster will run by choosing an AWS Region. Next, create the DB cluster. If you have data outside of Aurora, you can migrate the data into an Aurora DB cluster.

Creating an Amazon Aurora DB cluster

An Amazon Aurora DB cluster consists of a DB instance, compatible with either MySQL or PostgreSQL, and a cluster volume that holds the data for the DB cluster, copied across three Availability Zones as a single, virtual volume. By default, an Aurora DB cluster contains a primary DB instance that performs reads and writes, and, optionally, up to 15 Aurora Replicas (reader DB instances). For more information about Aurora DB clusters, see [Amazon Aurora DB clusters \(p. 3\)](#).

Following, you can find out how to create an Aurora DB cluster. To get started, first see [DB cluster prerequisites \(p. 125\)](#).

For simple instructions on connecting to your Aurora DB cluster, see [Connecting to an Amazon Aurora DB cluster \(p. 281\)](#).

DB cluster prerequisites

Important

Before you can create an Aurora DB cluster, you must complete the tasks in [Setting up your environment for Amazon Aurora \(p. 84\)](#).

The following are prerequisites to create a DB cluster.

VPC, subnets, and AZs

You can create an Amazon Aurora DB cluster only in a virtual private cloud (VPC) based on the Amazon VPC service, in an AWS Region that has at least two Availability Zones. The DB subnet group that you choose for the DB cluster must cover at least two Availability Zones. This configuration ensures that your DB cluster always has at least one DB instance available for failover, in the unlikely event of an Availability Zone failure.

If you use the AWS Management Console to create your Aurora DB cluster, you can have Amazon RDS automatically create a VPC for you. Or you can use an existing VPC or create a new VPC for your Aurora DB cluster. Whichever approach you take, your VPC must have at least one subnet in each of at least two Availability Zones for you to use it with an Amazon Aurora DB cluster.

By default, Amazon RDS creates the primary DB instance and the Aurora Replica in the AZs automatically for you. To choose a specific AZ, you need to change the **Availability & durability** Multi-AZ deployment setting to **Don't create an Aurora Replica**. Doing so exposes a drop-down selector that lets you choose from among the AZs in your VPC. However, we strongly recommend that you keep the default setting and let Amazon RDS create a multi-AZ deployment and choose AZs for you. By doing so, your Aurora DB cluster is created with the fast failover and high availability features that are two of Aurora's key benefits.

For more information, see [How to create a VPC for use with Amazon Aurora \(p. 1793\)](#). For information on VPCs, see [Amazon Virtual Private Cloud VPCs](#) and [Amazon Aurora \(p. 1787\)](#).

Note

You can communicate with an EC2 instance that is not in a VPC and an Amazon Aurora DB cluster using ClassicLink. For more information, see [A DB instance in a VPC accessed by an EC2 instance not in a VPC \(p. 1803\)](#).

If you don't have a default VPC or you haven't created a VPC, you can have Amazon RDS automatically create a VPC for you when you create an Aurora DB cluster using the console. Otherwise, you must do the following:

- Create a VPC with at least one subnet in each of at least two of the Availability Zones in the AWS Region where you want to deploy your DB cluster. For more information, see [How to create a VPC for use with Amazon Aurora \(p. 1793\)](#).

- Specify a VPC security group that authorizes connections to your Aurora DB cluster. For more information, see [Working with a DB instance in a VPC \(p. 1788\)](#).
- Specify an RDS DB subnet group that defines at least two subnets in the VPC that can be used by the Aurora DB cluster. For more information, see [Working with DB subnet groups \(p. 1788\)](#).

Additional prerequisites

If you are connecting to AWS using AWS Identity and Access Management (IAM) credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see [Identity and access management in Amazon Aurora \(p. 1724\)](#).

If you are using IAM to access the Amazon RDS console, you must first sign on to the AWS Management Console with your IAM user credentials. Then go to the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

If you want to tailor the configuration parameters for your DB cluster, you must specify a DB cluster parameter group and DB parameter group with the required parameter settings. For information about creating or modifying a DB cluster parameter group or DB parameter group, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#).

You must determine the TCP/IP port number to specify for your DB cluster. The firewalls at some companies block connections to the default ports (3306 for MySQL, 5432 for PostgreSQL) for Aurora. If your company firewall blocks the default port, choose another port for your DB cluster. All instances in a DB cluster use the same port.

Creating a DB cluster

You can create an Aurora DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Note

If you are using the console, a new console interface is available for database creation. Choose either the **New Console** or the **Original Console** instructions based on the console that you are using. The **New Console** instructions are open by default.

New console

You can create a DB instance running MySQL with the AWS Management Console with **Easy create** enabled or not enabled. With **Easy create** enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default setting for other configuration options. With **Easy create** not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

Note

For this example, **Standard create** is enabled, and **Easy create** isn't enabled. For information about creating an Aurora MySQL DB cluster with **Easy create** enabled, see [Getting started with Amazon Aurora \(p. 89\)](#).

To create an Aurora DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the DB cluster.
Aurora is not available in all AWS Regions. For a list of AWS Regions where Aurora is available, see [Region availability \(p. 12\)](#).
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.

5. In **Choose a database creation method**, choose **Standard create**.
6. In **Engine options**, choose **Amazon Aurora**.

RDS > Create database

Create database

Choose a database creation method Info

Standard create
You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create
Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

Engine options

Engine type Info

Amazon Aurora 

MySQL 

MariaDB 

PostgreSQL 

Oracle 

Microsoft SQL Server 

Edition

Amazon Aurora with MySQL compatibility

Amazon Aurora with PostgreSQL compatibility

Capacity type Info

Provisioned
You provision and manage the server instance sizes.

7. In **Edition**, choose one of the following:

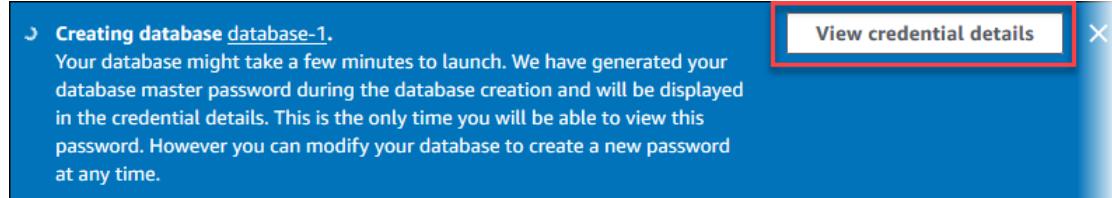

- **Amazon Aurora with MySQL compatibility**
 - **Amazon Aurora with PostgreSQL compatibility**
8. Choose one of the following in **Capacity type**:
- **Provisioned**
For more information, see [Amazon Aurora DB clusters \(p. 3\)](#).
 - **Serverless**
For more information, see [Using Amazon Aurora Serverless v1 \(p. 147\)](#).
9. For **Version**, choose the engine version.
10. In **Templates**, choose the template that matches your use case.
11. To enter your master password, do the following:
- a. In the **Settings** section, open **Credential Settings**.
 - b. Clear the **Auto generate a password** check box.
 - c. (Optional) Change the **Master username** value and enter the same password in **Master password** and **Confirm password**.

By default, the new DB instance uses an automatically generated password for the master user.

12. For the remaining sections, specify your DB cluster settings. For information about each setting, see [Settings for Aurora DB clusters \(p. 137\)](#).
13. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB cluster, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

14. For **Databases**, choose the name of the new Aurora DB cluster.

On the RDS console, the details for new DB cluster appear. The DB cluster and its DB instance have a status of **creating** until the DB cluster is ready to use.

The screenshot shows the 'Databases' page in the Amazon RDS console. At the top, there are two tabs: 'All' (selected) and 'By database group'. Below the tabs is a search bar labeled 'Filter databases'. The main area displays a table titled 'Databases' with the following data:

DB identifier	Role	Engine	Region & AZ
database-1	Regional cluster	Aurora MySQL	us-east-2
database-1-instance-1	Reader instance	Aurora MySQL	-

When the state changes to **available** for both, you can connect to the DB cluster. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB cluster is available.

To view the newly created cluster, choose **Databases** from the navigation pane in the Amazon RDS console. Then choose the DB cluster to show the DB cluster details. For more information, see [Viewing an Amazon Aurora DB cluster \(p. 547\)](#).

The screenshot shows the AWS RDS console interface for a database cluster named "database-1". The "Connectivity & security" tab is active. In the "Endpoints (2)" section, there are two entries:

Endpoint name	Status	Type	Port
database-1.cluster-ro-*.us-east-2.rds.amazonaws.com	Available	Reader instance	3306
database-1.cluster-*.us-east-2.rds.amazonaws.com	Available	Writer instance	3306

The "Writer instance" entry is highlighted with a red circle.

On the **Connectivity & security** tab, note the port and the endpoint of the writer DB instance. Use the endpoint and port of the cluster in your JDBC and ODBC connection strings for any application that performs write or read operations.

Original console

To create an Aurora DB cluster using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
 2. In the top-right corner of the AWS Management Console, choose the AWS Region in which you want to create the Aurora DB cluster.
 3. In the navigation pane, choose **Databases**.
- If the navigation pane is closed, choose the menu icon at the top left to open it.
4. Choose **Create database** to open the **Select engine** page.
 5. On the **Select engine** page, choose an edition of Aurora. Choose either MySQL 5.6-compatible, MySQL 5.7-compatible, MySQL 8.0-compatible, or PostgreSQL-compatible.

Microsoft SQL Server

Amazon Aurora

Amazon Aurora is a MySQL- and PostgreSQL-compatible enterprise-class database, starting at <\$1/day.

- Up to 5 times the throughput of MySQL and 3 times the throughput of PostgreSQL
- Up to 64TB of auto-scaling SSD storage
- 6-way replication across three Availability Zones
- Up to 15 Read Replicas with sub-10ms replica lag
- Automatic monitoring and failover in less than 30 seconds

Edition

- MySQL 5.6-compatible
- MySQL 5.7-compatible
- PostgreSQL-compatible

Only enable options eligible for RDS Free Usage Tier [info](#)

Cancel

Next

6. Choose **Next**.
7. On the **Specify DB details** page, specify your DB instance information. For information about each setting, see [Settings for Aurora DB clusters \(p. 137\)](#).

A typical **Specify DB details** page looks like the following.

Specify DB details

Instance specifications

Estimate your monthly costs for the DB Instance using the [AWS Simple Monthly Calculator](#).

DB engine
Aurora - compatible with MySQL 5.7.12

DB instance class [info](#)

Multi-AZ deployment [info](#)
 Create Replica in Different Zone
 No

Settings

DB instance identifier [info](#)
Specify a name that is unique for all DB instances owned by your AWS account in the current region.

DB instance identifier is case insensitive, but stored as all lower-case, as in "mydbinstance".

Master username [info](#)
Specify an alphanumeric string that defines the login ID for the master user.

Master Username must start with a letter.

Master password [info](#) Confirm password [info](#)

Master Password must be at least eight characters long, as in "mypassword".

[Cancel](#) [Previous](#) [Next](#)

8. Confirm your master password and choose **Next**.
9. On the **Configure advanced settings** page, you can customize additional settings for your Aurora DB cluster. For information about each setting, see [Settings for Aurora DB clusters \(p. 137\)](#).
10. Choose **Create database** to create your Aurora DB cluster, and then choose **Close**.

On the Amazon RDS console, the new DB cluster appears in the list of DB clusters. The DB cluster will have a status of **creating** until the DB cluster is created and ready for use. When the state changes to available, you can connect to the writer instance for your DB cluster. Depending on the DB cluster class and store allocated, it can take several minutes for the new cluster to be available.

To view the newly created cluster, choose **Databases** from the navigation pane in the Amazon RDS console and choose the DB cluster to show the DB cluster details. For more information, see [Viewing an Amazon Aurora DB cluster \(p. 547\)](#).

The screenshot shows the AWS RDS console interface for managing a database cluster named "gs-db-cluster1".

Related Databases:

DB identifier	Role	Engine
gs-db-cluster1	Regional	Aurora MySQL
gs-db-instance1	Writer	Aurora MySQL
gs-db-instance1-us-east-2b	Reader	Aurora MySQL

Endpoints (2):

Endpoint name	Status	Type
gs-db-cluster1. [REDACTED] .rds.amazonaws.com	Available	Writer
gs-db-cluster1. [REDACTED] .rds.amazonaws.com	Available	Reader

A red oval highlights the endpoint "gs-db-cluster1.[REDACTED].rds.amazonaws.com" under the "Writer" status.

Note the ports and the endpoints of the cluster. Use the endpoint and port of the writer DB cluster in your JDBC and ODBC connection strings for any application that performs write or read operations.

AWS CLI

Note

Before you can create an Aurora DB cluster using the AWS CLI, you must fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see [DB cluster prerequisites \(p. 125\)](#).

You can use the AWS CLI to create an Aurora MySQL DB cluster or an Aurora PostgreSQL DB cluster.

To create an Aurora MySQL DB cluster using the AWS CLI

When you create an Aurora MySQL DB cluster or DB instance, ensure that you specify the correct value for the `--engine` option value based on the MySQL compatibility of the DB cluster or DB instance.

- When you create an Aurora MySQL 8.0-compatible or 5.7-compatible DB cluster or DB instance, you specify `aurora-mysql` for the `--engine` option.
- When you create an Aurora MySQL 5.6-compatible DB cluster or DB instance, you specify `aurora` for the `--engine` option.

Complete the following steps:

1. Identify the DB subnet group and VPC security group ID for your new DB cluster, and then call the `create-db-cluster` AWS CLI command to create the Aurora MySQL DB cluster.

For example, the following command creates a new MySQL 8.0-compatible DB cluster named `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql \
  \
  --engine-version 8.0 --master-username user-name --master-user-password password \
  --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql \
  ^
  --engine-version 8.0 --master-username user-name --master-user-password password ^
  --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```

The following command creates a new MySQL 5.7-compatible DB cluster named `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql \
  \
  --engine-version 5.7.12 --master-username user-name --master-user-
  password password \
  --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql \
  ^
  --engine-version 5.7.12 --master-username user-name --master-user-password password
```

```
--db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```

The following command creates a new MySQL 5.6-compatible DB cluster named `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora \  
  --engine-version 5.6.10a --master-username user-name --master-user-  
  password password \  
  --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora ^  
  --engine-version 5.6.10a --master-username user-name --master-user-  
  password password ^  
  --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```

2. If you use the console to create a DB cluster, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to create a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

Call the [create-db-instance](#) AWS CLI command to create the primary instance for your DB cluster. Include the name of the DB cluster as the `--db-cluster-identifier` option value.

For example, the following command creates a new MySQL 5.7-compatible or MySQL 8.0-compatible DB instance named `sample-instance`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance --db-instance-identifier sample-instance \  
  --db-cluster-identifier sample-cluster --engine aurora-mysql --db-instance-class  
  db.r5.large
```

For Windows:

```
aws rds create-db-instance --db-instance-identifier sample-instance ^  
  --db-cluster-identifier sample-cluster --engine aurora-mysql --db-instance-class  
  db.r5.large
```

The following command creates a new MySQL 5.6-compatible DB instance named `sample-instance`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance --db-instance-identifier sample-instance \  
  --db-cluster-identifier sample-cluster --engine aurora --db-instance-class  
  db.r5.large
```

For Windows:

```
aws rds create-db-instance --db-instance-identifier sample-instance ^  
  --db-cluster-identifier sample-cluster --engine aurora --db-instance-class  
  db.r5.large
```

To create an Aurora PostgreSQL DB cluster using the AWS CLI

1. Identify the DB subnet group and VPC security group ID for your new DB cluster, and then call the [create-db-cluster](#) AWS CLI command to create the Aurora PostgreSQL DB cluster.

For example, the following command creates a new DB cluster named `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql \
    --master-username user-name --master-user-password password \
    --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql ^
    --master-username user-name --master-user-password password ^
    --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```

2. If you use the console to create a DB cluster, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to create a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

Call the [create-db-instance](#) AWS CLI command to create the primary instance for your DB cluster. Include the name of the DB cluster as the `--db-cluster-identifier` option value.

For Linux, macOS, or Unix:

```
aws rds create-db-instance --db-instance-identifier sample-instance \
    --db-cluster-identifier sample-cluster --engine aurora-postgresql --db-instance-class db.r4.large
```

For Windows:

```
aws rds create-db-instance --db-instance-identifier sample-instance ^
    --db-cluster-identifier sample-cluster --engine aurora-postgresql --db-instance-class db.r4.large
```

RDS API

Note

Before you can create an Aurora DB cluster using the AWS CLI, you must fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see [DB cluster prerequisites \(p. 125\)](#).

Identify the DB subnet group and VPC security group ID for your new DB cluster, and then call the [CreateDBCluster](#) operation to create the DB cluster.

When you create an Aurora MySQL DB cluster or DB instance, ensure that you specify the correct value for the `Engine` parameter value based on the MySQL compatibility of the DB cluster or DB instance.

- When you create an Aurora MySQL 5.7 DB cluster or DB instance, you must specify `aurora-mysql` for the `Engine` parameter.

- When you create an Aurora MySQL 5.6 DB cluster or DB instance, you must specify `aurora` for the `Engine` parameter.

When you create an Aurora PostgreSQL DB cluster or DB instance, specify `aurora-postgresql` for the `Engine` parameter.

Settings for Aurora DB clusters

The following table contains details about settings that you choose when you create an Aurora DB cluster.

Note

Additional settings are available if you are creating an Aurora Serverless DB cluster. For information about these settings, see [Creating an Aurora Serverless v1 DB cluster \(p. 161\)](#). Also, some settings aren't available for Aurora Serverless because of Aurora Serverless limitations. For more information, see [Limitations of Aurora Serverless v1 \(p. 148\)](#).

Console setting	Setting description	CLI option and RDS API parameter
Auto minor version upgrade	<p>Choose Enable auto minor version upgrade if you want to enable your Aurora DB cluster to receive preferred minor version upgrades to the DB engine automatically when they become available.</p> <p>The Auto minor version upgrade setting applies to both Aurora PostgreSQL and Aurora MySQL DB clusters. For Aurora MySQL version 1 and version 2 clusters, this setting upgrades the clusters to a maximum version of 1.22.2 and 2.07.2, respectively.</p> <p>For more information about engine updates for Aurora PostgreSQL, see Amazon Aurora PostgreSQL updates (p. 1597).</p> <p>For more information about engine updates for Aurora MySQL, see Database engine updates for Amazon Aurora MySQL (p. 1082).</p>	<p>Set this value for every DB instance in your Aurora cluster. If any DB instance in your cluster has this setting turned off, the cluster isn't automatically upgraded.</p> <p>Using the AWS CLI, run <code>create-db-instance</code> and set the <code>--auto-minor-version-upgrade --no-auto-minor-version-upgrade</code> option.</p> <p>Using the RDS API, call <code>CreateDBInstance</code> and set the <code>AutoMinorVersionUpgrade</code> parameter.</p>
AWS KMS key	<p>Only available if Encryption is set to Enable encryption. Choose the AWS KMS key to use for encrypting this DB cluster. For more information, see Encrypting Amazon Aurora resources (p. 1709).</p>	<p>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--kms-key-id</code> option.</p> <p>Using the RDS API, call <code>CreateDBCluster</code> and set the <code>KmsKeyId</code> parameter.</p>
Backtrack	<p>Applies only to Aurora MySQL. Choose Enable Backtrack to enable backtracking or Disable Backtrack to disable backtracking. Using</p>	<p>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--backtrack-window</code> option.</p>

Console setting	Setting description	CLI option and RDS API parameter
	backtracking, you can rewind a DB cluster to a specific time, without creating a new DB cluster. It is disabled by default. If you enable backtracking, also specify the amount of time that you want to be able to backtrack your DB cluster (the target backtrack window). For more information, see Backtracking an Aurora DB cluster (p. 816) .	Using the RDS API, call CreateDBCluster and set the BacktrackWindow parameter.
Copy tags to snapshots	Choose this option to copy any DB instance tags to a DB snapshot when you create a snapshot. For more information, see Tagging Amazon RDS resources (p. 474) .	Using the AWS CLI, run create-db-cluster and set the --copy-tags-to-snapshot --no-copy-tags-to-snapshot option. Using the RDS API, call CreateDBCluster and set the CopyTagsToSnapshot parameter.
Database authentication	The database authentication you want to use. For MySQL: <ul style="list-style-type: none">• Choose Password authentication to authenticate database users with database passwords only.• Choose Password and IAM database authentication to authenticate database users with database passwords and user credentials through IAM users and roles. For more information, see IAM database authentication (p. 1743). For PostgreSQL: <ul style="list-style-type: none">• Choose IAM database authentication to authenticate database users with database passwords and user credentials through IAM users and roles. For more information, see IAM database authentication (p. 1743).• Choose Kerberos authentication to authenticate database passwords and user credentials using Kerberos authentication. For more information, see Using Kerberos authentication with Aurora PostgreSQL (p. 1534).	To use IAM database authentication with the AWS CLI, run create-db-cluster and set the --enable-iam-database-authentication --no-enable-iam-database-authentication option. To use IAM database authentication with the RDS API, call CreateDBCluster and set the EnableIAMDatabaseAuthentication parameter. To use Kerberos authentication with the AWS CLI, run create-db-cluster and set the --domain and --domain-iam-role-name options. To use Kerberos authentication with the RDS API, call CreateDBCluster and set the Domain and DomainIAMRoleName parameters.

Console setting	Setting description	CLI option and RDS API parameter
Database port	<p>Specify the port for applications and utilities to use to access the database. Aurora MySQL DB clusters default to the default MySQL port, 3306, and Aurora PostgreSQL DB clusters default to the default PostgreSQL port, 5432. The firewalls at some companies block connections to these default ports. If your company firewall blocks the default port, choose another port for the new DB cluster.</p>	<p>Using the AWS CLI, run create-db-cluster and set the --port option.</p> <p>Using the RDS API, call CreateDBCluster and set the Port parameter.</p>
DB cluster identifier	<p>Enter a name for your DB cluster that is unique for your account in the AWS Region that you chose. This identifier is used in the cluster endpoint address for your DB cluster. For information on the cluster endpoint, see Amazon Aurora connection management (p. 32).</p> <p>The DB cluster identifier has the following constraints:</p> <ul style="list-style-type: none"> • It must contain from 1 to 63 alphanumeric characters or hyphens. • Its first character must be a letter. • It cannot end with a hyphen or contain two consecutive hyphens. • It must be unique for all DB clusters per AWS account, per AWS Region. 	<p>Using the AWS CLI, run create-db-cluster and set the --db-cluster-identifier option.</p> <p>Using the RDS API, call CreateDBCluster and set the DBClusterIdentifier parameter.</p>
DB cluster parameter group	<p>Choose a DB cluster parameter group. Aurora has a default DB cluster parameter group you can use, or you can create your own DB cluster parameter group. For more information about DB cluster parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 339).</p>	<p>Using the AWS CLI, run create-db-cluster and set the --db-cluster-parameter-group-name option.</p> <p>Using the RDS API, call CreateDBCluster and set the DBClusterParameterGroupName parameter.</p>
DB instance class	<p>Applies only to the provisioned capacity type. Choose a DB instance class that defines the processing and memory requirements for each instance in the DB cluster. For more information about DB instance classes, see Aurora DB instance classes (p. 54).</p>	<p>Set this value for every DB instance in your Aurora cluster.</p> <p>Using the AWS CLI, run create-db-instance and set the --db-instance-class option.</p> <p>Using the RDS API, call CreateDBInstance and set the DBInstanceClass parameter.</p>

Console setting	Setting description	CLI option and RDS API parameter
DB parameter group	Choose a parameter group. Aurora has a default parameter group you can use, or you can create your own parameter group. For more information about parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 339) .	<p>Set this value for every DB instance in your Aurora cluster.</p> <p>Using the AWS CLI, run create-db-instance and set the --db-parameter-group-name option.</p> <p>Using the RDS API, call CreateDBInstance and set the DBParameterGroupName parameter.</p>
Enable deletion protection	Choose Enable deletion protection to prevent your DB cluster from being deleted. If you create a production DB cluster with the console, deletion protection is enabled by default.	<p>Using the AWS CLI, run create-db-cluster and set the --deletion-protection --no-deletion-protection option.</p> <p>Using the RDS API, call CreateDBCluster and set the DeletionProtection parameter.</p>
Enable encryption	Choose Enable encryption to enable encryption at rest for this DB cluster. For more information, see Encrypting Amazon Aurora resources (p. 1709) .	<p>Using the AWS CLI, run create-db-cluster and set the --storage-encrypted --no-storage-encrypted option.</p> <p>Using the RDS API, call CreateDBCluster and set the StorageEncrypted parameter.</p>
Enable Enhanced Monitoring	Choose Enable enhanced monitoring to enable gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 626) .	<p>Set these values for every DB instance in your Aurora cluster.</p> <p>Using the AWS CLI, run create-db-instance and set the --monitoring-interval and --monitoring-role-arn options.</p> <p>Using the RDS API, call CreateDBInstance and set the MonitoringInterval and MonitoringRoleArn parameters.</p>

Console setting	Setting description	CLI option and RDS API parameter
Enable Performance Insights	Choose Enable Performance Insights to enable Amazon RDS Performance Insights. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 573) .	<p>Set these values for every DB instance in your Aurora cluster.</p> <p>Using the AWS CLI, run <code>create-db-instance</code> and set the <code>--enable-performance-insights</code> <code>--no-enable-performance-insights</code>, <code>--performance-insights-kms-key-id</code>, and <code>--performance-insights-retention-period</code> options.</p> <p>Using the RDS API, call <code>CreateDBInstance</code> and set the <code>EnablePerformanceInsights</code>, <code>PerformanceInsightsKMSKeyId</code>, and <code>PerformanceInsightsRetentionPeriod</code> parameters.</p>
Engine type	Choose the database engine to be used for this DB cluster.	<p>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--engine</code> option.</p> <p>Using the RDS API, call <code>CreateDBCluster</code> and set the <code>Engine</code> parameter.</p>
Engine version	Applies only to the provisioned capacity type. Choose the version number of your DB engine.	<p>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--engine-version</code> option.</p> <p>Using the RDS API, call <code>CreateDBCluster</code> and set the <code>EngineVersion</code> parameter.</p>
Failover priority	Choose a failover priority for the instance. If you don't choose a value, the default is tier-1 . This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. For more information, see Fault tolerance for an Aurora DB cluster (p. 69) .	<p>Set this value for every DB instance in your Aurora cluster.</p> <p>Using the AWS CLI, run <code>create-db-instance</code> and set the <code>--promotion-tier</code> option.</p> <p>Using the RDS API, call <code>CreateDBInstance</code> and set the <code>PromotionTier</code> parameter.</p>

Console setting	Setting description	CLI option and RDS API parameter
Initial database name	<p>Enter a name for your default database. If you don't provide a name for an Aurora MySQL DB cluster, Amazon RDS doesn't create a database on the DB cluster you are creating. If you don't provide a name for an Aurora PostgreSQL DB cluster, Amazon RDS creates a database named <code>postgres</code>.</p> <p>For Aurora MySQL, the default database name has these constraints:</p> <ul style="list-style-type: none"> • It must contain 1–64 alphanumeric characters. • It can't be a word reserved by the database engine. <p>For Aurora PostgreSQL, the default database name has these constraints:</p> <ul style="list-style-type: none"> • It must contain 1–63 alphanumeric characters. • It must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0–9). • It can't be a word reserved by the database engine. <p>To create additional databases, connect to the DB cluster and use the SQL command <code>CREATE DATABASE</code>. For more information about connecting to the DB cluster, see Connecting to an Amazon Aurora DB cluster (p. 281).</p>	<p>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--database-name</code> option.</p> <p>Using the RDS API, call <code>CreateDBCluster</code> and set the <code>DatabaseName</code> parameter.</p>
Log exports	<p>In the Log exports section, choose the logs that you want to start publishing to Amazon CloudWatch Logs. For more information about publishing Aurora MySQL logs to CloudWatch Logs, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 1017). For more information about publishing Aurora PostgreSQL logs to CloudWatch Logs, see Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs (p. 1487).</p>	<p>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--enable-cloudwatch-logs-exports</code> option.</p> <p>Using the RDS API, call <code>CreateDBCluster</code> and set the <code>EnableCloudwatchLogsExports</code> parameter.</p>

Console setting	Setting description	CLI option and RDS API parameter
Maintenance window	Choose Select window and specify the weekly time range during which system maintenance can occur. Or choose No preference for Amazon RDS to assign a period randomly.	Using the AWS CLI, run create-db-cluster and set the --preferred-maintenance-window option. Using the RDS API, call CreateDBCluster and set the PreferredMaintenanceWindow parameter.
Master password	Enter a password to log on to your DB cluster: <ul style="list-style-type: none">• For Aurora MySQL, the password must contain 8–41 printable ASCII characters.• For Aurora PostgreSQL, it must contain 8–128 printable ASCII characters.• It can't contain /, ", @, or a space.	Using the AWS CLI, run create-db-cluster and set the --master-user-password option. Using the RDS API, call CreateDBCluster and set the MasterUserPassword parameter.
Master username	Enter a name to use as the master user name to log on to your DB cluster: <ul style="list-style-type: none">• For Aurora MySQL, the name must contain 1–16 alphanumeric characters.• For Aurora PostgreSQL, it must contain 1–63 alphanumeric characters.• The first character must be a letter.• The name can't be a word reserved by the database engine.	Using the AWS CLI, run create-db-cluster and set the --master-username option. Using the RDS API, call CreateDBCluster and set the MasterUsername parameter.
Multi-AZ deployment	Applies only to the provisioned capacity type. Determine if you want to create Aurora Replicas in other Availability Zones for failover support. If you choose Create Replica in Different Zone , then Amazon RDS creates an Aurora Replica for you in your DB cluster in a different Availability Zone than the primary instance for your DB cluster. For more information about multiple Availability Zones, see Regions and Availability Zones (p. 11) .	Using the AWS CLI, run create-db-cluster and set the --availability-zones option. Using the RDS API, call CreateDBCluster and set the AvailabilityZones parameter.

Console setting	Setting description	CLI option and RDS API parameter
Option group	Aurora has a default option group.	Using the AWS CLI, run create-db-cluster and set the --option-group-name option. Using the RDS API, call CreateDBCluster and set the OptionGroupName parameter.
Public access	<p>Choose Publicly accessible to give the DB cluster a public IP address, or choose Not publicly accessible. The instances in your DB cluster can be a mix of both public and private DB instances. For more information about hiding instances from public access, see Hiding a DB instance in a VPC from the internet (p. 1789).</p> <p>To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 1814).</p> <p>If your DB instance is isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 1723).</p>	Set this value for every DB instance in your Aurora cluster. Using the AWS CLI, run create-db-instance and set the --publicly-accessible --no-publicly-accessible option. Using the RDS API, call CreateDBInstance and set the PubliclyAccessible parameter.
Retention period	Choose the length of time, from 1 to 35 days, that Aurora retains backup copies of the database. Backup copies can be used for point-in-time restores (PITR) of your database down to the second.	Using the AWS CLI, run create-db-cluster and set the --backup-retention-period option. Using the RDS API, call CreateDBCluster and set the BackupRetentionPeriod parameter.
Subnet group	Choose the DB subnet group to use for the DB cluster. For more information, see DB cluster prerequisites (p. 125) .	Using the AWS CLI, run create-db-cluster and set the --db-subnet-group-name option. Using the RDS API, call CreateDBCluster and set the DBSubnetGroupName parameter.

Console setting	Setting description	CLI option and RDS API parameter
Virtual Private Cloud (VPC)	Choose the VPC to host the DB cluster. Choose Create a New VPC to have Amazon RDS create a VPC for you. For more information, see DB cluster prerequisites (p. 125) .	For the AWS CLI and API, you specify the VPC security group IDs.
VPC security group	<p>Choose Create new to have Amazon RDS create a VPC security group for you. Or choose Choose existing and specify one or more VPC security groups to secure network access to the DB cluster.</p> <p>When you choose Create new in the RDS console, a new security group is created with an inbound rule that allows access to the DB instance from the IP address detected in your browser.</p> <p>For more information, see DB cluster prerequisites (p. 125).</p>	<p>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--vpc-security-group-ids</code> option.</p> <p>Using the RDS API, call <code>CreateDBCluster</code> and set the <code>VpcSecurityGroupIds</code> parameter.</p>

Creating Amazon Aurora resources with AWS CloudFormation

Amazon Aurora is integrated with AWS CloudFormation, a service that helps you to model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want (such as DB clusters and DB cluster parameter groups), and AWS CloudFormation provisions and configures those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your Aurora resources consistently and repeatedly. Describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

Aurora and AWS CloudFormation templates

To provision and configure resources for Aurora and related services, you must understand [AWS CloudFormation templates](#). Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you're unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see [What is AWS CloudFormation Designer?](#) in the [AWS CloudFormation User Guide](#).

Aurora supports creating resources in AWS CloudFormation. For more information, including examples of JSON and YAML templates for these resources, see the [RDS resource type reference](#) in the [AWS CloudFormation User Guide](#).

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- [AWS CloudFormation](#)
- [AWS CloudFormation User Guide](#)
- [AWS CloudFormation API Reference](#)
- [AWS CloudFormation Command Line Interface User Guide](#)

Using Amazon Aurora Serverless v1

Amazon Aurora Serverless v1 (Amazon Aurora Serverless version 1) is an on-demand autoscaling configuration for Amazon Aurora. An *Aurora Serverless DB cluster* is a DB cluster that scales compute capacity up and down based on your application's needs. This contrasts with Aurora *provisioned DB clusters*, for which you manually manage capacity. Aurora Serverless v1 provides a relatively simple, cost-effective option for infrequent, intermittent, or unpredictable workloads. It is cost-effective because it automatically starts up, scales compute capacity to match your application's usage, and shuts down when it's not in use.

To learn more about pricing, see [Serverless Pricing](#) under **MySQL-Compatible Edition** or **PostgreSQL-Compatible Edition** on the Amazon Aurora pricing page.

Aurora Serverless v1 clusters have the same kind of high-capacity, distributed, and highly available storage volume that is used by provisioned DB clusters. The cluster volume for an Aurora Serverless v1 cluster is always encrypted. You can choose the encryption key, but you can't disable encryption. That means that you can perform the same operations on an Aurora Serverless v1 that you can on encrypted snapshots. For more information, see [Aurora Serverless v1 and snapshots \(p. 161\)](#).

Advantages of Aurora Serverless v1

Aurora Serverless v1 provides the following advantages:

- **Simpler than provisioned** – Aurora Serverless v1 removes much of the complexity of managing DB instances and capacity.
- **Scalable** – Aurora Serverless v1 seamlessly scales compute and memory capacity as needed, with no disruption to client connections.
- **Cost-effective** – When you use Aurora Serverless v1, you pay only for the database resources that you consume, on a per-second basis.
- **Highly available storage** – Aurora Serverless v1 uses the same fault-tolerant, distributed storage system with six-way replication as Aurora to protect against data loss.

Use cases for Aurora Serverless v1

Aurora Serverless v1 is designed for the following use cases:

- **Infrequently used applications** – You have an application that is only used for a few minutes several times per day or week, such as a low-volume blog site. With Aurora Serverless v1, you pay for only the database resources that you consume on a per-second basis.
- **New applications** – You're deploying a new application and you're unsure about the instance size you need. By using Aurora Serverless v1, you can create a database endpoint and have the database autoscale to the capacity requirements of your application.
- **Variable workloads** – You're running a lightly used application, with peaks of 30 minutes to several hours a few times each day, or several times per year. Examples are applications for human resources, budgeting, and operational reporting applications. With Aurora Serverless v1, you no longer need to provision for peak or average capacity.
- **Unpredictable workloads** – You're running daily workloads that have sudden and unpredictable increases in activity. An example is a traffic site that sees a surge of activity when it starts raining. With Aurora Serverless v1, your database autoscales capacity to meet the needs of the application's peak load and scales back down when the surge of activity is over.
- **Development and test databases** – Your developers use databases during work hours but don't need them on nights or weekends. With Aurora Serverless v1, your database automatically shuts down when it's not in use.
- **Multi-tenant applications** – With Aurora Serverless v1, you don't have to individually manage database capacity for each application in your fleet. Aurora Serverless v1 manages individual database capacity for you.

Limitations of Aurora Serverless v1

The following limitations apply to Aurora Serverless v1:

- You can't use Aurora MySQL version 3 for Aurora Serverless v1 clusters. Aurora MySQL version 3 works with Aurora Serverless v2, which is currently in preview.
- Aurora Serverless v1 is available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see [Aurora Serverless v1 \(p. 29\)](#).
- Aurora Serverless v1 doesn't support the following features:
 - Aurora global databases
 - Aurora multi-master clusters
 - Aurora Replicas
 - AWS Identity and Access Management (IAM) database authentication
 - Backtracking in Aurora
 - Database activity streams
 - Performance Insights
- Connections to an Aurora Serverless v1 DB cluster are closed automatically if held open for longer than one day.
- All Aurora Serverless v1 DB clusters have the following limitations:
 - You can't export Aurora Serverless v1 snapshots to Amazon S3 buckets.
 - You can't save data to text files in Amazon S3.
 - You can't use AWS Database Migration Service and Change Data Capture (CDC) with Aurora Serverless DB clusters. Only provisioned Aurora DB clusters support CDC with AWS DMS as a source.
 - You can't load text file data to Aurora MySQL Serverless from Amazon S3. However, you can load data to Aurora PostgreSQL Serverless from Amazon S3 by using the `aws_s3` extension with

the `aws_s3.table_import_from_s3` function and the `credentials` parameter. For more information, see [Importing Amazon S3 data into an Aurora PostgreSQL DB cluster \(p. 1438\)](#).

- Aurora MySQL-based DB clusters running Aurora Serverless v1 don't support the following:
 - Invoking AWS Lambda functions from within your Aurora MySQL DB cluster. However, AWS Lambda functions can make calls to your Aurora MySQL Serverless DB cluster.
 - Restoring a snapshot from a DB instance that isn't Aurora MySQL or RDS for MySQL.
 - Replicating data using replication based on binary logs (binlogs). This limitation is true regardless of whether your Aurora MySQL-based DB cluster Aurora Serverless v1 is the source or the target of the replication. To replicate data into an Aurora Serverless v1 DB cluster from a MySQL DB instance outside Aurora, such as one running on Amazon EC2, consider using AWS Database Migration Service. For more information, see the [AWS Database Migration Service User Guide](#).
- Aurora PostgreSQL-based DB clusters running Aurora Serverless v1 have the following limitations:
 - Aurora PostgreSQL query plan management (`apg_plan_management` extension) isn't supported.
 - The logical replication feature available in Amazon RDS PostgreSQL and Aurora PostgreSQL isn't supported.
 - Outbound communications such as those enabled by Amazon RDS for PostgreSQL extensions aren't supported. For example, you can't access external data with the `postgres_fdw/dblink` extension. For more information about RDS PostgreSQL extensions, see [PostgreSQL on Amazon RDS](#) in the *RDS User Guide*.
 - Currently, certain SQL queries and commands aren't recommended. These include session-level advisory locks, temporary relations, asynchronous notifications (`LISTEN`), and cursors with hold (`DECLARE name ... CURSOR WITH HOLD FOR query`). Also, `NOTIFY` and `COPY` commands prevent scaling and aren't recommended.

For more information, see [Autoscaling for Aurora Serverless v1 \(p. 153\)](#).

- You can't set the preferred backup window for an Aurora Serverless v1 DB cluster.

Configuration requirements for Aurora Serverless v1

When you create an Aurora Serverless v1 DB cluster, pay attention to the following requirements:

- Use these specific port numbers for each DB engine:
 - Aurora MySQL – 3306
 - Aurora PostgreSQL – 5432
- Create your Aurora Serverless v1 DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. When you create an Aurora Serverless v1 DB cluster in your VPC, you consume two (2) of the fifty (50) Interface and Gateway Load Balancer endpoints allotted to your VPC. These endpoints are created automatically for you. To increase your quota, you can contact AWS Support. For more information, see [Amazon VPC quotas](#).
- You can't give an Aurora Serverless v1 DB cluster a public IP address. You can access an Aurora Serverless v1 DB cluster only from within a VPC.
- Create subnets in different Availability Zones for the DB subnet group that you use for your Aurora Serverless v1 DB cluster. In other words, you can't have more than one subnet in the same Availability Zone.
- Changes to a subnet group used by an Aurora Serverless v1 DB cluster aren't applied to the cluster.
- You can access an Aurora Serverless v1 DB cluster from AWS Lambda. To do so, you must configure your Lambda function to run in the same VPC as your Aurora Serverless v1 DB cluster. For more information about working with AWS Lambda, see [Configuring a Lambda function to access resources in an Amazon VPC](#) in the *AWS Lambda Developer Guide*.

Using TLS/SSL with Aurora Serverless v1

By default, Aurora Serverless v1 uses the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt communications between clients and your Aurora Serverless v1 DB cluster. It supports TLS/SSL versions 1.0, 1.1, and 1.2. You don't need to configure your Aurora Serverless v1 DB cluster to use TLS/SSL.

However, the following limitations apply:

- TLS/SSL support for Aurora Serverless v1 DB clusters isn't currently available in the China (Beijing) AWS Region.
- When you create database users for an Aurora MySQL-based Aurora Serverless v1 DB cluster, don't use the `REQUIRE` clause for SSL permissions. Doing so prevents users from connecting to the Aurora DB instance.
- For both MySQL Client and PostgreSQL Client utilities, session variables that you might use in other environments have no effect when using TLS/SSL between client and Aurora Serverless v1.
- For the MySQL Client, when connecting with TLS/SSL's `VERIFY_IDENTITY` mode, currently you need to use the MySQL 8.0-compatible `mysql` command. For more information, see [Connecting to a DB instance running the MySQL database engine](#).

Depending on the client that you use to connect to Aurora Serverless v1 DB cluster, you might not need to specify TLS/SSL to get an encrypted connection. For example, to use the PostgreSQL Client to connect to an Aurora Serverless v1 DB cluster running Aurora PostgreSQL-Compatible Edition, connect as you normally do.

```
psql -h endpoint -U user
```

After you enter your password, the PostgreSQL Client shows you see the connection details, including the TLS/SSL version and cipher.

```
psql (12.5 (Ubuntu 12.5-0ubuntu0.20.04.1), server 10.12)
SSL connection (protocol: TLSv1.2, cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256,
compression: off)
Type "help" for help.
```

Important

Aurora Serverless v1 uses the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt connections by default unless SSL/TLS is disabled by the client application. The TLS/SSL connection terminates at the router fleet. Communication between the router fleet and your Aurora Serverless v1 DB cluster occurs within the service's internal network boundary.

You can check the status of the client connection to examine whether the connection to Aurora Serverless v1 is TLS/SSL encrypted. The PostgreSQL `pg_stat_ssl` and `pg_stat_activity` tables and its `ssl_is_used` function don't show the TLS/SSL state for the communication between the client application and Aurora Serverless v1. Similarly, the TLS/SSL state can't be derived from the MySQL `status` statement.

The Aurora cluster parameters `force_ssl` for PostgreSQL and `require_secure_transport` for MySQL aren't supported for Aurora Serverless v1. For a complete list of parameters supported by Aurora Serverless v1, call the [DescribeEngineDefaultClusterParameters](#) API. For more information on parameter groups and Aurora Serverless v1, see [Parameter groups and Aurora Serverless v1 \(p. 156\)](#).

To use the MySQL Client to connect to an Aurora Serverless v1 DB cluster running Aurora MySQL-Compatible Edition, you specify TLS/SSL in your request. The following example includes the [Amazon root CA 1 trust store](#) downloaded from Amazon Trust Services, which is necessary for this connection to succeed.

```
mysql -h endpoint -P 3306 -u user -p --ssl-ca=amazon-root-CA-1.pem --ssl-mode=REQUIRED
```

When prompted, enter your password. Soon, the MySQL monitor opens. You can confirm that the session is encrypted by using the `status` command.

```
mysql> status
-----
mysql Ver 14.14 Distrib 5.5.62, for Linux (x86_64) using readline 5.1
Connection id:          19
Current database:
Current user:          ***@*****
SSL:                  Cipher in use is ECDHE-RSA-AES256-SHA
...
```

To learn more about connecting to Aurora MySQL database with the MySQL Client, see [Connecting to a DB instance running the MySQL database engine](#).

Aurora Serverless v1 supports all TLS/SSL modes available to the MySQL Client (`mysql`) and PostgreSQL Client (`psql`), including those listed in the following table.

Description of TLS/SSL mode	<code>mysql</code>	<code>psql</code>
Connect without using TLS/SSL.	DISABLED	disable
Try the connection using TLS/SSL first, but fall back to non-SSL if necessary.	PREFERRED	prefer (default)
Enforce using TLS/SSL.	REQUIRED	require
Enforce TLS/SSL and verify the CA.	VERIFY_CA	verify-ca
Enforce TLS/SSL, verify the CA, and verify the CA hostname.	VERIFY_IDENTITY	verify-full

Aurora Serverless v1 uses wildcard certificates. If you specify the "verify CA" or the "verify CA and CA hostname" option when using TLS/SSL, first download the [Amazon root CA 1 trust store](#) from Amazon Trust Services. After doing so, you can identify this PEM-formatted file in your client command. To do so using the PostgreSQL Client:

For Linux, macOS, or Unix:

```
psql 'host=endpoint user=user sslmode=require sslrootcert=amazon-root-CA-1.pem dbname=db-name'
```

To learn more about working with the Aurora PostgreSQL database using the Postgres Client, see [Connecting to a DB instance running the PostgreSQL database engine](#).

For more information about connecting to Aurora DB clusters in general, see [Connecting to an Amazon Aurora DB cluster \(p. 281\)](#).

How Aurora Serverless v1 works

Amazon Aurora offers two different DB engine modes aimed at two broadly different usage models.

The *provisioned* DB engine mode is designed for predictable workloads. When you work with Aurora provisioned DB clusters, you choose your DB instance class size and several other configuration options. For example, you can create one or more Aurora Replicas to increase read throughput. If your workload changes, you can modify the DB instance class size and change the number of Aurora Replicas. The provisioned model works well when you can adjust capacity in advance of expected consumption patterns.

The *serverless* DB engine mode is designed for a different usage pattern entirely. For example, your database usage might be heavy for a short period of time, followed by long periods of light activity or no activity at all. Some examples are retail websites with intermittent sales events, databases that produce reports when needed, development and testing environments, and new applications with uncertain requirements. For cases such as these and many others, configuring capacity correctly in advance isn't always possible with the provisioned model. It can also result in higher costs if you overprovision and have capacity that you don't use.

By using Aurora Serverless v1, you can create a database endpoint without specifying the DB instance class size. You specify only the minimum and maximum range for the Aurora Serverless v1 DB cluster's capacity. The Aurora Serverless v1 database endpoint makes up a *router fleet* that supports continuous connections and distributes the workload among resources. Aurora Serverless v1 scales the resources automatically based on your minimum and maximum capacity specifications.

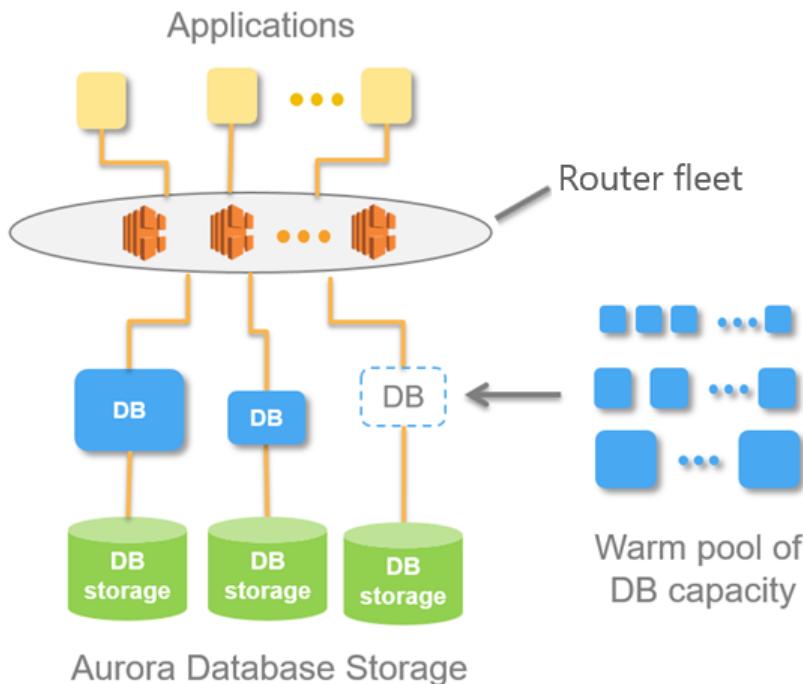

You don't need to change your database client application code to use the router fleet. Aurora Serverless v1 manages the connections automatically. Scaling is fast thanks to a "warm" resources pool that's always ready to service requests. Storage and processing are separate, so your Aurora Serverless v1 DB cluster can scale down to zero when it's finished processing workloads. When your Aurora Serverless v1 DB cluster scales to zero, you're charged only for storage.

Aurora Serverless v1 architecture

The following image shows an overview the Aurora Serverless v1 architecture.

Instead of provisioning and managing database servers, you specify Aurora capacity units (ACUs). Each ACU is a combination of approximately 2 gigabytes (GB) of memory, corresponding CPU, and networking. Database storage automatically scales from 10 gibibytes (GiB) to 128 tebibytes (TiB), the same as storage in a standard Aurora DB cluster.

You can specify the minimum and maximum ACU. The *minimum Aurora capacity unit* is the lowest ACU to which the DB cluster can scale down. The *maximum Aurora capacity unit* is the highest ACU to which the DB cluster can scale up. Based on your settings, Aurora Serverless v1 automatically creates scaling rules for thresholds for CPU utilization, connections, and available memory.

Aurora Serverless v1 manages the warm pool of resources in an AWS Region to minimize scaling time. When Aurora Serverless v1 adds new resources to the Aurora DB cluster, it uses the router fleet to switch active client connections to the new resources. At any specific time, you are only charged for the ACUs that are being actively used in your Aurora DB cluster.

Autoscaling for Aurora Serverless v1

The capacity allocated to your Aurora Serverless v1 DB cluster seamlessly scales up and down based on the load generated by your client application. Here, load is CPU utilization and the number of connections. When capacity is constrained by either of these, Aurora Serverless v1 scales up. Aurora Serverless also scales up when it detects performance issues that can be resolved by doing so.

You can view scaling events for your Aurora Serverless cluster in the AWS Management Console. During autoscaling, Aurora Serverless v1 resets the `EngineUptime` metric. The value of the reset metric value doesn't mean that seamless scaling had problems, nor does it mean Aurora Serverless dropped connections. It's simply the starting point for uptime at the new capacity. To learn more about metrics, see [Monitoring metrics in an Amazon Aurora cluster \(p. 541\)](#).

When your Aurora Serverless v1 DB cluster has no active connections, it can scale down to zero capacity (0 ACUs). To learn more, see [Pause and resume for Aurora Serverless v1 \(p. 155\)](#).

When it does need to perform a scaling operation, Aurora Serverless v1 first tries to identify a *scaling point*, a moment when no queries are being processed. Aurora Serverless might not be able to find a scaling point for the following reasons:

- Long-running queries
- In-progress transactions
- Temporary tables or table locks

To increase your Aurora Serverless DB cluster's success rate when finding a scaling point, we recommend that you avoid long-running queries and long-running transactions. To learn more about scale-blocking operations and how to avoid them, see [Best practices for working with Amazon Aurora Serverless](#).

By default, Aurora Serverless v1 tries to find a scaling point for 5 minutes (300 seconds). You can specify a different timeout period when you create or modify the cluster. The timeout period can be between 60 seconds and 10 minutes (600 seconds). If Aurora Serverless can't find a scaling point within the specified period, the autoscaling operation times out.

By default, if autoscaling doesn't find a scaling point before timing out, Aurora Serverless v1 keeps the cluster at the current capacity. You can change this default behavior when you create or modify your Aurora Serverless DB cluster by selecting the **Force the capacity change** option. For more information, see [Timeout action for capacity changes \(p. 154\)](#).

Timeout action for capacity changes

If autoscaling times out without finding a scaling point, by default Aurora keeps the current capacity. You can choose to have Aurora force the change by enabling the **Force the capacity change** option. This option is available in the **Autoscaling timeout and action** section of the Create database page, when you create the cluster.

- **Force the capacity change** – By default, this option is deselected. Leave this option unchecked to have your Aurora Serverless DB cluster's capacity to remain unchanged if the scaling operation times out without finding a scaling point.
- **Force the capacity change** – Choosing this option causes your Aurora Serverless DB cluster to enforce the capacity change, even without a scaling point. Before enabling this option, be aware of the consequences of this choice.
 - Any in-process transactions are interrupted, and the following error message appears.

Aurora MySQL 5.6 – ERROR 1105 (HY000): The last transaction was aborted due to an unknown error. Please retry.

Aurora MySQL 5.7 – ERROR 1105 (HY000): The last transaction was aborted due to Seamless Scaling. Please retry.

You can resubmit the transactions as soon as your Aurora Serverless v1 DB cluster is available.

- Connections to temporary tables and locks are dropped.

Note

We recommend that you choose the "force" option only if your application can recover from dropped connections or incomplete transactions.

The choices you make in the AWS Management Console when you create an Aurora Serverless DB cluster are stored in the `ScalingConfigurationInfo` object, in the `SecondsBeforeTimeout` and `TimeoutAction` properties. The value of the `TimeoutAction` property is set to one of the following values when you create your cluster:

- `RollbackCapacityChange` – This value is set when you choose the **Roll back the capacity change** option. This is the default behavior.
- `ForceApplyCapacityChange` – This value is set when you choose the **Force the capacity change** option.

You can get the value of this property on an existing Aurora Serverless DB cluster by using the [describe-db-clusters](#) AWS CLI command, as shown following.

For Linux, macOS, or Unix:

```
aws rds describe-db-clusters --region region \  
  --db-cluster-identifier your-cluster-name \  
  --query '*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}'
```

For Windows:

```
aws rds describe-db-clusters --region region ^  
  --db-cluster-identifier your-cluster-name ^  
  --query "*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}"
```

As an example, the following shows the query and response for an Aurora Serverless v1 DB cluster named `west-coast-sles` in the US West (N. California) Region.

```
$ aws rds describe-db-clusters --region us-west-1 --db-cluster-identifier west-coast-sles  
--query '*[].{ScalingConfigurationInfo:ScalingConfigurationInfo}'  
  
[  
  {  
    "ScalingConfigurationInfo": {  
      "MinCapacity": 1,  
      "MaxCapacity": 64,  
      "AutoPause": false,  
      "SecondsBeforeTimeout": 300,  
      "SecondsUntilAutoPause": 300,  
      "TimeoutAction": "RollbackCapacityChange"  
    }  
  }  
]
```

As the response shows, this Aurora Serverless v1 DB cluster uses the default setting.

For more information, see [Creating an Aurora Serverless v1 DB cluster \(p. 161\)](#). After creating your Aurora Serverless v1, you can modify the timeout action and other capacity settings at any time. To learn how, see [Modifying an Aurora Serverless v1 DB cluster \(p. 170\)](#).

Pause and resume for Aurora Serverless v1

You can choose to pause your Aurora Serverless v1 DB cluster after a given amount of time with no activity. You specify the amount of time with no activity before the DB cluster is paused. When you select this option, the default inactivity time is five minutes, but you can change this value. This is an optional setting.

When the DB cluster is paused, no compute or memory activity occurs, and you are charged only for storage. If database connections are requested when an Aurora Serverless DB cluster is paused, the DB cluster automatically resumes and services the connection requests.

When the DB cluster resumes activity, it has the same capacity as it had when Aurora paused the cluster. The number of ACUs depends on how much Aurora scaled the cluster up or down before pausing it.

Note

If a DB cluster is paused for more than seven days, the DB cluster might be backed up with a snapshot. In this case, Aurora restores the DB cluster from the snapshot when there is a request to connect to it.

Parameter groups and Aurora Serverless v1

When you create your Aurora Serverless v1 DB cluster, you choose a specific Aurora DB engine and an associated DB cluster parameter group. Unlike provisioned Aurora DB clusters, an Aurora Serverless DB cluster has a single read/write DB instance that's configured with a DB cluster parameter group only—it doesn't have a separate DB parameter group. During autoscaling, Aurora Serverless needs to be able to change parameters for the cluster to work best for the increased or decreased capacity. Thus, with an Aurora Serverless DB cluster, some of the changes you might make to parameters for a particular DB engine type might not apply.

For example, an Aurora PostgreSQL-based Aurora Serverless DB cluster can't use `apg_plan_mgmt.capture_plan_baselines` and other parameters that might be used on provisioned Aurora PostgreSQL DB clusters for query plan management.

You can get a list of default values for the default parameter groups for the various Aurora DB engines by using the `describe-engine-default-cluster-parameters` CLI command and querying the AWS Region. The following are values you can use for the `--db-parameter-group-family` option.

Aurora MySQL 5.6	<code>aurora5.6</code>
Aurora MySQL 5.7	<code>aurora-mysql5.7</code>
Aurora PostgreSQL 10.12 (and later)	<code>aurora-postgresql10</code>

We recommend that you configure your AWS CLI with your AWS Access Key ID and AWS Secret Access Key, and that you set your AWS Region before using AWS CLI commands. Providing the Region to your CLI configuration saves you from entering the `--region` parameter when running commands. To learn more about configuring AWS CLI, see [Configuration basics](#) in the AWS Command Line Interface User Guide.

The following example gets a list of parameters from the default DB cluster group for Aurora MySQL 5.6.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-cluster-parameters \
--db-parameter-group-family aurora5.6 --query \
'EngineDefaults.Parameters[*]' \
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | [?
contains(SupportedEngineModes, `serverless`) == `true`] | [*].{param:ParameterName}' \
--output text
```

For Windows:

```
aws rds describe-engine-default-cluster-parameters ^
--db-parameter-group-family aurora5.6 --query ^
"EngineDefaults.Parameters[*]" \
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} | [?
contains(SupportedEngineModes, 'serverless') == 'true'] | [*].{param:ParameterName}" ^
--output text
```

Modifying parameter values for Aurora Serverless v1

As explained in [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#), you can't directly change values in a default parameter group, regardless of its type (DB cluster parameter group, DB parameter group). Instead, you create a custom parameter group based on the default DB cluster

parameter group for your Aurora DB engine and change settings as needed on that parameter group. For example, you might want to change some of the settings for your Aurora Serverless DB cluster to [log queries or to upload DB engine specific logs \(p. 158\)](#) to Amazon CloudWatch.

To create a custom DB cluster parameter group

1. Sign in to the AWS Management Console and then open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Parameter groups**.
3. Choose **Create parameter group** to open the Parameter group details pane.
4. Choose the appropriate default DB cluster group for the DB engine you want to use for your Aurora Serverless v1 DB cluster. Be sure you choose the following options:
 - a. For **Parameter group family**, choose the appropriate family for your chosen DB engine. Be sure your selection has the prefix `aurora-` in its name.
 - b. For **Type**, choose **DB Cluster Parameter Group**.
 - c. For **Group name** and **Description**, enter meaningful names for you or others who might need to work with your Aurora Serverless v1 DB cluster and its parameters.
 - d. Choose **Create**.

Your custom DB cluster parameter group is added to the list of parameter groups available in your AWS Region. You can use your custom DB cluster parameter group when you create new Aurora Serverless DB clusters, and you can modify an existing Aurora Serverless DB cluster to use your custom DB cluster parameter group. Once your Aurora Serverless DB cluster starts using your custom DB cluster parameter group, you can change values for dynamic parameters using either the AWS Management Console or the AWS CLI. You can also use the Console to view a side-by-side comparison of the values in your custom DB cluster parameter group compared to the default DB cluster parameter group, as shown in the following screenshot.

Parameter	my-db-cluster-param-group-for-mysql-logs	default.aurora-mysql5.7
general_log	1	<engine-default>
log_queries_not_using_indexes	1	<engine-default>
long_query_time	60	<engine-default>
server_audit_events	CONNECT	<engine-default>
server_audit_logging	1	0
server_audit_logs_upload	1	0
slow_query_log	1	<engine-default>

Close

When you change parameter values on an active DB cluster, Aurora Serverless starts a seamless scale in order to apply the parameter changes. If your Aurora Serverless DB cluster is in a "paused" state, it

resumes and starts scaling so that it can make the change. The scaling operation for a parameter group change always [forces the capacity change \(p. 154\)](#), so be aware that modifying parameters might result in dropped connections if a scaling point can't be found during the scaling period.

Logging for Aurora Serverless v1

By default, error logs for Aurora Serverless are enabled and automatically uploaded to Amazon CloudWatch. You can also have your Aurora Serverless DB cluster upload Aurora database-engine specific logs to CloudWatch by enabling configuration parameters in your custom DB cluster parameter group. Your Aurora Serverless DB cluster then uploads all available logs to Amazon CloudWatch, and you can use CloudWatch to analyze log data, create alarms, and view metrics.

For Aurora MySQL, you can enable the following logs have them automatically uploaded from your Aurora Serverless DB cluster to Amazon CloudWatch.

Aurora MySQL	Description
general_log	Creates the general log. Set to 1 to turn on. Default is off (0).
log_queries_not_using_indexes	Logs any queries to the slow query log that don't use an index. Default is off (0). Set to 1 to turn on this log.
long_query_time	Prevents fast-running queries from being logged in the slow query log. Can be set to a float between 0 and 31536000. Default is 0 (not active).
server_audit_events	The list of events to capture in the logs. Supported values are CONNECT, QUERY, QUERY_DCL, QUERY_DDL, QUERY_DML, and TABLE.
server_audit_logging	Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the server_audit_events parameter.
slow_query_log	Creates a slow query log. Set to 1 to turn on the slow query log. Default is off (0).

For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster \(p. 914\)](#).

For Aurora PostgreSQL, you can enable the following logs on your Aurora Serverless DB cluster and have them automatically uploaded to Amazon CloudWatch along with the regular error logs.

Aurora PostgreSQL	Description
log_connections	Enabled by default, and can't be changed. It logs details for all new client connections.
log_disconnections	Enabled by default, and can't be changed. Logs all client disconnections.
log_lock_waits	Default is 0 (off). Set to 1 to log lock waits.

Aurora PostgreSQL	Description
<code>log_min_duration_statement</code>	The minimum duration (in milliseconds) for a statement to run before it's logged.
<code>log_min_messages</code>	Sets the message levels that are logged. Supported values are <code>debug5</code> , <code>debug4</code> , <code>debug3</code> , <code>debug2</code> , <code>debug1</code> , <code>info</code> , <code>notice</code> , <code>warning</code> , <code>error</code> , <code>log</code> , <code>fatal</code> , <code>panic</code> . To log performance data to the <code>postgres</code> log, set the value to <code>debug1</code> .
<code>log_temp_files</code>	Logs the use of temporary files that are above the specified kilobytes (kB).
<code>log_statement</code>	Controls the specific SQL statements that get logged. Supported values are <code>none</code> , <code>ddl</code> , <code>mod</code> , and <code>all</code> . Default is <code>none</code> .

After you enable logs for Aurora MySQL 5.6, Aurora MySQL 5.7, or Aurora PostgreSQL for your Aurora Serverless DB cluster, you can view the logs in CloudWatch.

Viewing Aurora Serverless v1 logs with Amazon CloudWatch

Aurora Serverless v1 automatically uploads ("publishes") to Amazon CloudWatch all logs that are enabled in your custom DB cluster parameter group. You don't need to choose or specify the log types. Uploading logs starts as soon as you enable the log configuration parameter. If you later disable the log parameter, further uploads stop. However, all the logs that have already been published to CloudWatch remain until you delete them.

For more information on using CloudWatch with Aurora MySQL logs, see [Monitoring log events in Amazon CloudWatch \(p. 1020\)](#).

For more information about CloudWatch and Aurora PostgreSQL, see [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs \(p. 1487\)](#).

To view logs for your Aurora Serverless DB cluster

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose your AWS Region.
3. Choose **Log groups**.
4. Choose your Aurora Serverless DB cluster log from the list. For error logs, the naming pattern is as follows.

```
/aws/rds/cluster/cluster-name/error
```

For example, in the following screenshot you can find listings for logs published for an Aurora PostgreSQL Aurora Serverless DB cluster named "western-sles." You can also find several listings for Aurora MySQL Aurora Serverless DB cluster, "west-coast-sles." Choose the log of interest to start exploring its content.

The screenshot shows the AWS CloudWatch Log Groups interface. At the top, there are navigation links: CloudWatch > CloudWatch Logs > Log groups. Below this, a header bar includes 'Log groups (5)', a search bar, and buttons for Actions, View in Logs Insights, and Create log group. A note says 'By default, we only load up to 10000 log groups.' A search bar with a placeholder 'Filter log groups or try prefix search' is followed by an 'Exact match' checkbox and navigation arrows. The main table lists five log groups:

Log group	Retention	Metric filters	Contributor Insights
/aws/rds/cluster/west-coast-sles/audit	Never expire	-	-
/aws/rds/cluster/west-coast-sles/error	Never expire	-	-
/aws/rds/cluster/west-coast-sles/general	Never expire	-	-
/aws/rds/cluster/western-sles/postgresql	Never expire	-	-

Aurora Serverless v1 and maintenance

Maintenance for Aurora Serverless v1 DB cluster, such as applying the latest features, fixes, and security updates, is performed automatically for you. Unlike provisioned Aurora DB clusters, Aurora Serverless doesn't have user-settable maintenance windows. However, it does have a maintenance window that you can view in the AWS Management Console in **Maintenance & backups** for your Aurora Serverless DB cluster. You can find the date and time that maintenance might be performed and if any maintenance is pending for your Aurora Serverless DB cluster, as shown following.

The screenshot shows the AWS Management Console with the 'Maintenance & backups' tab selected. The interface includes tabs for Connectivity & security, Monitoring, Logs & events, Configuration, Maintenance & backups (which is highlighted in red), and Tags. Under the Maintenance section, it shows:

Maintenance window	Pending maintenance
tue:08:41-tue:09:11 UTC (GMT)	none

Whenever possible, Aurora Serverless performs maintenance in a non-disruptive manner. When maintenance is required, your Aurora Serverless DB cluster scales its capacity to handle the necessary operations. Before scaling, Aurora Serverless looks for a scaling point and it does so for up to seven days if necessary.

At the end of each day that Aurora Serverless can't find a scaling point, it creates a cluster event. This event notifies you of the pending maintenance and the need to scale to perform maintenance. The notification includes the date when the Aurora Serverless can force the DB cluster to scale.

Until that time, your Aurora Serverless DB cluster continues looking for a scaling point and behaves according to its `TimeoutAction` setting. That is, if it can't find a scaling point before timing out, it abandons the capacity change if it's configured to `RollbackCapacityChange`. Or it forces the change if it's set to `ForceApplyCapacityChange`. As with any change that's forced without an appropriate scaling point, this might interrupt your workload.

For more information, see [Timeout action for capacity changes \(p. 154\)](#).

Aurora Serverless v1 and failover

If the DB instance for an Aurora Serverless v1 DB cluster becomes unavailable or the Availability Zone (AZ) it is in fails, Aurora recreates the DB instance in a different AZ. We refer to this capability as automatic multi-AZ failover.

This failover mechanism takes longer than for an Aurora provisioned cluster. The Aurora Serverless v1 failover time is currently undefined because it depends on demand and capacity availability in other AZs within the given AWS Region.

Because Aurora separates computation capacity and storage, the storage volume for the cluster is spread across multiple AZs. Your data remains available even if outages affect the DB instance or the associated AZ.

Aurora Serverless v1 and snapshots

The cluster volume for an Aurora Serverless v1 cluster is always encrypted. You can choose the encryption key, but you can't disable encryption. To copy or share a snapshot of an Aurora Serverless v1 cluster, you encrypt the snapshot using your own AWS KMS key. For more information, see [Copying a DB cluster snapshot](#). To learn more about encryption and Amazon Aurora, see [Encrypting Amazon Aurora resources](#).

Creating an Aurora Serverless v1 DB cluster

When you create an Aurora Serverless v1 DB cluster, you can set the minimum and maximum capacity for the cluster. A capacity unit is equivalent to a specific compute and memory configuration. Aurora Serverless creates scaling rules for thresholds for CPU utilization, connections, and available memory and seamlessly scales to a range of capacity units as needed for your applications. For more information see [Aurora Serverless v1 architecture \(p. 152\)](#).

You can set the following specific values for your Aurora Serverless v1 DB cluster:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.

You can also choose the following optional scaling configuration options:

- **Roll back the capacity change** – To cancel capacity changes if Aurora Serverless v1 can't find a scaling point, choose this setting.

Force the capacity change – To force Aurora Serverless v1 to scale even if it can't find a scaling point before it times out, choose this setting.

For more information, see [Timeout action for capacity changes \(p. 154\)](#).

- **Pause compute capacity after consecutive minutes of inactivity** – You can choose this setting if you want Aurora Serverless v1 to scale to zero when there's no activity on your DB cluster for an amount of time you specify. With this setting enabled, your Aurora Serverless v1 DB cluster automatically resumes processing and scales to the necessary capacity to handle the workload when database traffic resumes. To learn more, see [Pause and resume for Aurora Serverless v1 \(p. 155\)](#).

Before you can create an Aurora Serverless v1 DB cluster, you need an AWS account. You also need to have completed the setup tasks for working with Amazon Aurora. For more information, see [Setting up your environment for Amazon Aurora \(p. 84\)](#). You also need to complete other preliminary steps for creating any Aurora DB cluster. To learn more, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

Aurora Serverless v1 is available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see [Aurora Serverless v1 \(p. 29\)](#).

Note

The cluster volume for an Aurora Serverless v1 cluster is always encrypted. When you create your Aurora Serverless v1 DB cluster, you can't turn off encryption, but you can choose to use your own encryption key.

You can create an Aurora Serverless v1 DB cluster with the AWS Management Console, the AWS CLI, or the RDS API by following the steps below.

Console

To create a new Aurora Serverless v1 DB cluster, you sign in to the AWS Management Console and choose an AWS Region that supports Aurora Serverless v1. Choose Amazon RDS from the AWS Services list, and then choose **Create database**.

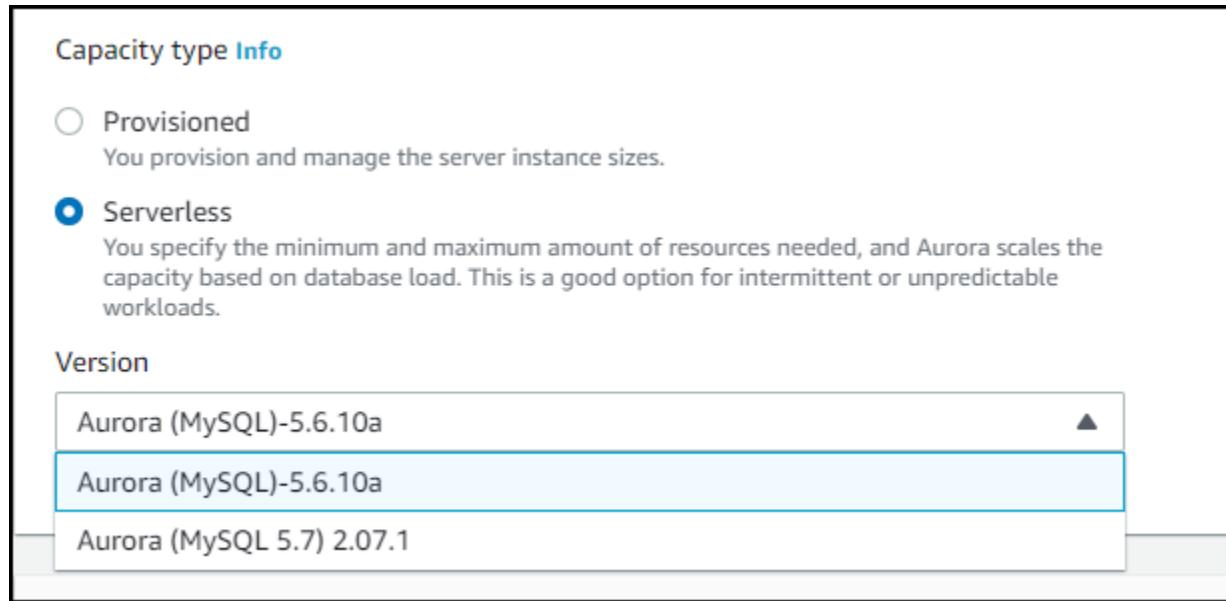

On the **Create database** page:

- Choose **Standard Create** for the database creation method.
- Choose **Amazon Aurora** for the Engine type in the **Engine options** section.

You then choose **Amazon Aurora with MySQL compatibility** or **Amazon Aurora with PostgreSQL compatibility** and continue creating the Aurora Serverless v1 DB cluster by using the steps from the following examples. If you choose a version of the DB engine that doesn't support Aurora Serverless v1, the **Serverless** option doesn't display.

Example for Aurora MySQL

Choose **Amazon Aurora with MySQL Compatibility** for the Edition. Choose the Aurora MySQL engine you want for your cluster from the **Version** selector. The following image shows an example.

Choose **Serverless** for the Capacity type.

You can configure the scaling configuration of the Aurora Serverless v1 DB cluster by adjusting values in the **Capacity settings** section of the page. To learn more about capacity settings, see [Autoscaling for Aurora Serverless v1 \(p. 153\)](#). The following image shows the **Capacity settings** you can adjust for an Aurora MySQL Serverless DB cluster.

Capacity settings

This billing estimate is based on published prices. [Learn more](#)

Minimum Aurora capacity unit Info	Maximum Aurora capacity unit Info
<input type="text" value="1"/> 2GB RAM	<input type="text" value="256"/> 488GB RAM

▼ Additional scaling configuration

Force scaling the capacity to the specified values when the timeout is reached [Info](#)
Enable to force capacity scaling as soon as possible. Disable to cancel the capacity changes when a timeout is reached

Pause compute capacity after consecutive minutes of inactivity [Info](#)
You are only charged for database storage while the compute capacity is paused

<input type="text" value="0"/> hours	<input type="text" value="5"/> minutes	<input type="text" value="0"/> seconds
--------------------------------------	--	--

Max: 24 hours

You can also enable the Data API for your Aurora MySQL Serverless DB cluster. Select the **Data API** checkbox in the **Connectivity** section of the Create database page. To learn more about the Data API, see [Using the Data API for Aurora Serverless \(p. 178\)](#).

Example for Aurora PostgreSQL

Choose **Amazon Aurora with Postgres; Compatibility** for the Edition and select the **Version** of Aurora PostgreSQL available for Aurora Serverless v1. For more information, see [Aurora Serverless v1 \(p. 29\)](#).

Capacity type [Info](#)

Provisioned
You provision and manage the server instance sizes.

Serverless
You specify the minimum and maximum amount of resources needed, and Aurora scales the capacity based on database load. This is a good option for intermittent or unpredictable workloads.

Version

Aura PostgreSQL (compatible with PostgreSQL 10.7) ▼

To see more versions, modify the capacity types. [Info](#)

You can configure the scaling configuration of the Aurora Serverless v1 DB cluster by adjusting values in the **Capacity settings** section of the page. The following image shows the **Capacity settings** you can adjust for an Aurora PostgreSQL Serverless DB cluster. To learn more about capacity settings, see [Autoscaling for Aurora Serverless v1 \(p. 153\)](#).

▼ Additional scaling configuration

Force scaling the capacity to the specified values when the timeout is reached [Info](#)
Enable to force capacity scaling as soon as possible. Disable to cancel the capacity changes when a timeout is reached

Pause compute capacity after consecutive minutes of inactivity [Info](#)
You are only charged for database storage while the compute capacity is paused

0 ▼ hours 5 ▼ minutes 0 ▼ seconds

Max: 24 hours

You can also enable the Data API for your Aurora PostgreSQL Serverless DB cluster. Select the **Data API** checkbox in the **Connectivity** section of the Create database page. See [Using the Data API for Aurora Serverless \(p. 178\)](#) for more information about the Data API.

For more information on creating an Aurora DB cluster using the AWS Management Console, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

Note

If you receive the following error message when trying to create your cluster, your account needs additional permissions.

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.

See [Using service-linked roles for Amazon Aurora \(p. 1783\)](#) for more information.

You can't directly connect to the DB instance on your Aurora Serverless v1 DB cluster. To connect to your Aurora Serverless v1 DB cluster, you use the database endpoint. You can find the endpoint for your Aurora Serverless v1 DB cluster on the **Connectivity & security** tab for your cluster in the AWS Management Console. For more information, see [Connecting to an Amazon Aurora DB cluster \(p. 281\)](#).

AWS CLI

To create a new Aurora Serverless v1 DB cluster with the AWS CLI, run the `create-db-cluster` command and specify `serverless` for the `--engine-mode` option.

You can optionally specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections.

The following command examples create a new Serverless DB cluster by setting the `--engine-mode` option to `serverless`. The examples also specify values for the `--scaling-configuration` option.

Example for Aurora MySQL

The following commands create new MySQL-compatible Serverless DB clusters. Valid capacity values for Aurora MySQL are 1, 2, 4, 8, 16, 32, 64, 128, and 256.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora --engine-version 5.6.10a \
--engine-mode serverless --scaling-configuration
MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true \
--master-username username --master-user-password password

aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.07.1 \
--engine-mode serverless --scaling-configuration
MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true \
--master-username username --master-user-password password
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora --engine-version 5.6.10a ^
--engine-mode serverless --scaling-configuration
MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true ^
--master-username username --master-user-password password
```

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql --  
engine-version 5.7.mysql_aurora.2.07.1 ^  
--engine-mode serverless --scaling-configuration  
MinCapacity=4,MaxCapacity=32,SecondsUntilAutoPause=1000,AutoPause=true ^  
--master-username username --master-user-password password
```

Example for Aurora PostgreSQL

The following command creates a new PostgreSQL 10.12–compatible Serverless DB cluster. Valid capacity values for Aurora PostgreSQL are 2, 4, 8, 16, 32, 64, 192, and 384.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql  
--engine-version 10.12 ^  
--engine-mode serverless --scaling-configuration  
MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=1000,AutoPause=true ^  
--master-username username --master-user-password password
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql  
--engine-version 10.12 ^  
--engine-mode serverless --scaling-configuration  
MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=1000,AutoPause=true ^  
--master-username username --master-user-password password
```

RDS API

To create a new Aurora Serverless v1 DB cluster with the RDS API, run the [CreateDBCluster](#) operation and specify `serverless` for the `EngineMode` parameter.

You can optionally specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

Restoring an Aurora Serverless v1 DB cluster

You can configure an Aurora Serverless v1 DB cluster when you restore a provisioned DB cluster snapshot with the AWS Management Console, the AWS CLI, or the RDS API.

When you restore a snapshot to an Aurora Serverless v1 DB cluster, you can set the following specific values:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.
- **Timeout action** – The action to take when a capacity modification times out because it can't find a scaling point. Aurora Serverless v1 DB cluster can force your DB cluster to the new capacity settings if

set the **Force scaling the capacity to the specified values...** option. Or, it can roll back the capacity change to cancel it if you don't choose the option. For more information, see [Timeout action for capacity changes \(p. 154\)](#).

- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

For general information about restoring a DB cluster from a snapshot, see [Restoring from a DB cluster snapshot \(p. 497\)](#).

Console

You can restore a DB cluster snapshot to an Aurora DB cluster with the AWS Management Console.

To restore a DB cluster snapshot to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region that hosts your source DB cluster.
3. In the navigation pane, choose **Snapshots**, and choose the DB cluster snapshot that you want to restore.
4. For **Actions**, choose **Restore Snapshot**.
5. On the **Restore DB Cluster** page, choose **Serverless** for **Capacity type**.

The screenshot shows the 'Restore DB Cluster' wizard with the following details:

- Instance specifications**
- DB Engine**: Aurora MySQL
- DB Engine Version**: Aurora (MySQL)-5.6.10a (default)
- Capacity type**:
 - Provisioned**: You provision and manage the server instance sizes.
 - Serverless**: You specify the minimum and maximum of resources for a DB cluster. Aurora scales the capacity based on database load (currently available for Aurora MySQL 5.6).

6. In the **DB cluster identifier** field, type the name for your restored DB cluster, and complete the other fields.
7. In the **Capacity settings** section, modify the scaling configuration.

The screenshot shows the 'Capacity settings' section of the AWS console. It includes fields for 'Minimum Aurora capacity unit' (set to 1, 2GB RAM) and 'Maximum Aurora capacity unit' (set to 256, 488GB RAM). Below these are sections for 'Additional scaling configuration' and 'Pause compute capacity after consecutive minutes of inactivity'. The 'Pause compute capacity after consecutive minutes of inactivity' option is checked, and its settings are shown: 0 hours, 5 minutes, and 0 seconds. A note indicates a maximum of 24 hours.

You are only charged for database storage while the compute capacity is paused

0 ▾ hours 5 ▾ minutes 0 ▾ seconds

Max: 24 hours

8. Choose **Restore DB Cluster**.

To connect to an Aurora Serverless v1 DB cluster, use the database endpoint. For details, see the instructions in [Connecting to an Amazon Aurora DB cluster \(p. 281\)](#).

Note

If you encounter the following error message, your account requires additional permissions:
Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.
For more information, see [Using service-linked roles for Amazon Aurora \(p. 1783\)](#).

AWS CLI

You can configure an Aurora Serverless v1 DB cluster when you restore from a snapshot of another DB cluster. You can do so with the AWS CLI by using the `restore-db-cluster-from-snapshot` CLI command. With your command, you include the following required parameters:

- `--db-cluster-identifier mynewdbcluster`
- `--snapshot-identifier mydbclustersnapshot`
- `--engine-mode serverless`

To restore a snapshot to an Aurora Serverless v1 cluster with MySQL 5.7 compatibility, include the following additional parameters:

- `--engine aurora-mysql`

- **--engine-version 5.7**

The `--engine` and `--engine-version` parameters let you create a MySQL 5.7-compatible Aurora Serverless v1 cluster from a MySQL 5.6-compatible Aurora or Aurora Serverless v1 snapshot. The following example restores a snapshot from a MySQL 5.6-compatible cluster named `mydbclustersnapshot` to a MySQL 5.7-compatible Aurora Serverless v1 cluster named `mynewdbcluster`.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
--db-cluster-identifier mynewdbcluster \
--snapshot-identifier mydbclustersnapshot \
--engine-mode serverless \
--engine aurora-mysql \
--engine-version 5.7
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
--db-instance-identifier mynewdbcluster ^
--db-snapshot-identifier mydbclustersnapshot ^
--engine aurora-mysql ^
--engine-version 5.7
```

You can optionally specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In the following example, you restore from a previously created DB cluster snapshot named `mydbclustersnapshot` to a new DB cluster named `mynewdbcluster`. You set the `--scaling-configuration` so that the new Aurora Serverless DB cluster can scale from 8 ACUs to 64 ACUs (Aurora capacity units) as needed to process the workload. After processing completes and after 1000 seconds with no connections to support, the cluster shuts down until connection requests prompt it to restart.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
--db-cluster-identifier mynewdbcluster \
--snapshot-identifier mydbclustersnapshot \
--engine-mode serverless --scaling-configuration
MinCapacity=8,MaxCapacity=64,TimeoutAction='ForceApplyCapacityChange',SecondsUntilAutoPause=1000,AutoP
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
--db-instance-identifier mynewdbcluster ^
--db-snapshot-identifier mydbclustersnapshot ^
--engine-mode serverless --scaling-configuration
MinCapacity=8,MaxCapacity=64,TimeoutAction='ForceApplyCapacityChange',SecondsUntilAutoPause=1000,AutoP
```

RDS API

To configure an Aurora Serverless v1 DB cluster when you restore from a DB cluster using the RDS API, run the [RestoreDBClusterFromSnapshot](#) operation and specify `serverless` for the `EngineMode` parameter.

You can optionally specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

Modifying an Aurora Serverless v1 DB cluster

After you configure an Aurora Serverless v1 DB cluster, you can modify its scaling configuration with the AWS Management Console, the AWS CLI, or the RDS API.

You can set the minimum and maximum capacity for the DB cluster. Each capacity unit is equivalent to a specific compute and memory configuration. Aurora Serverless v1 automatically creates scaling rules for thresholds for CPU utilization, connections, and available memory. You can also set whether Aurora Serverless v1 pauses the database when there's no activity and then resumes when activity begins again.

You can set the following specific values:

- **Minimum Aurora capacity unit** – Aurora Serverless v1 can reduce capacity down to this capacity unit.
- **Maximum Aurora capacity unit** – Aurora Serverless v1 can increase capacity up to this capacity unit.
- **Autoscaling timeout and action** – This section specifies how long Aurora Serverless waits to find a scaling point before timing out. It also specifies the action to take when a capacity modification times out because it can't find a scaling point. Aurora can force the capacity change to set the capacity to the specified value as soon as possible. Or, it can roll back the capacity change to cancel it. For more information, see [Timeout action for capacity changes \(p. 154\)](#).
- **Pause after inactivity** – The amount of time with no database traffic to scale to zero processing capacity. When database traffic resumes, Aurora automatically resumes processing capacity and scales to handle the traffic.

Console

You can modify the scaling configuration of an Aurora DB cluster with the AWS Management Console.

To modify an Aurora Serverless v1 DB cluster

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v1 DB cluster that you want to modify.
4. For **Actions**, choose **Modify cluster**.
5. In the **Capacity settings** section, modify the scaling configuration.

Capacity settings

This billing estimate is based on published prices. [Learn more](#)

Minimum Aurora capacity unit Info	Maximum Aurora capacity unit Info
<input type="text" value="1"/> 2GB RAM	<input type="text" value="256"/> 488GB RAM

▼ Additional scaling configuration

Enable to force capacity scaling as soon as possible. Disable to cancel the capacity changes when a timeout is reached

Pause compute capacity after consecutive minutes of inactivity [Info](#)
You are only charged for database storage while the compute capacity is paused

<input type="text" value="0"/> hours	<input type="text" value="5"/> minutes	<input type="text" value="0"/> seconds
Max: 24 hours		

6. Choose **Continue**.
7. Choose **Modify cluster**.

The change is applied immediately.

AWS CLI

To modify the scaling configuration of an Aurora Serverless v1 DB cluster using the AWS CLI, run the [modify-db-cluster](#) AWS CLI command. Specify the `--scaling-configuration` option to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In this example, you modify the scaling configuration of an Aurora Serverless v1 DB cluster named `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster \
--scaling-configuration
MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=500,TimeoutAction='ForceApplyCapacityChange',AutoPa
```

For Windows:

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster ^
--scaling-configuration
MinCapacity=8,MaxCapacity=64,SecondsUntilAutoPause=500,TimeoutAction='ForceApplyCapacityChange',AutoPa
```

RDS API

You can modify the scaling configuration of an Aurora DB cluster with the [ModifyDBCluster API](#) operation. Specify the `ScalingConfiguration` parameter to configure the minimum capacity, maximum capacity, and automatic pause when there are no connections. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

Scaling Aurora Serverless v1 DB cluster capacity manually

Typically, Aurora Serverless v1 DB clusters scale seamlessly based on the workload. However, capacity might not always scale fast enough to meet sudden extremes, such as an exponential increase in transactions. In such cases you can initiate the scaling operation manually by setting a new capacity value. After you set the capacity explicitly, Aurora Serverless v1 automatically scales the DB cluster. It does so based on the cooldown period for scaling down.

You can explicitly set the capacity of an Aurora Serverless v1 DB cluster to a specific value with the AWS Management Console, the AWS CLI, or the RDS API.

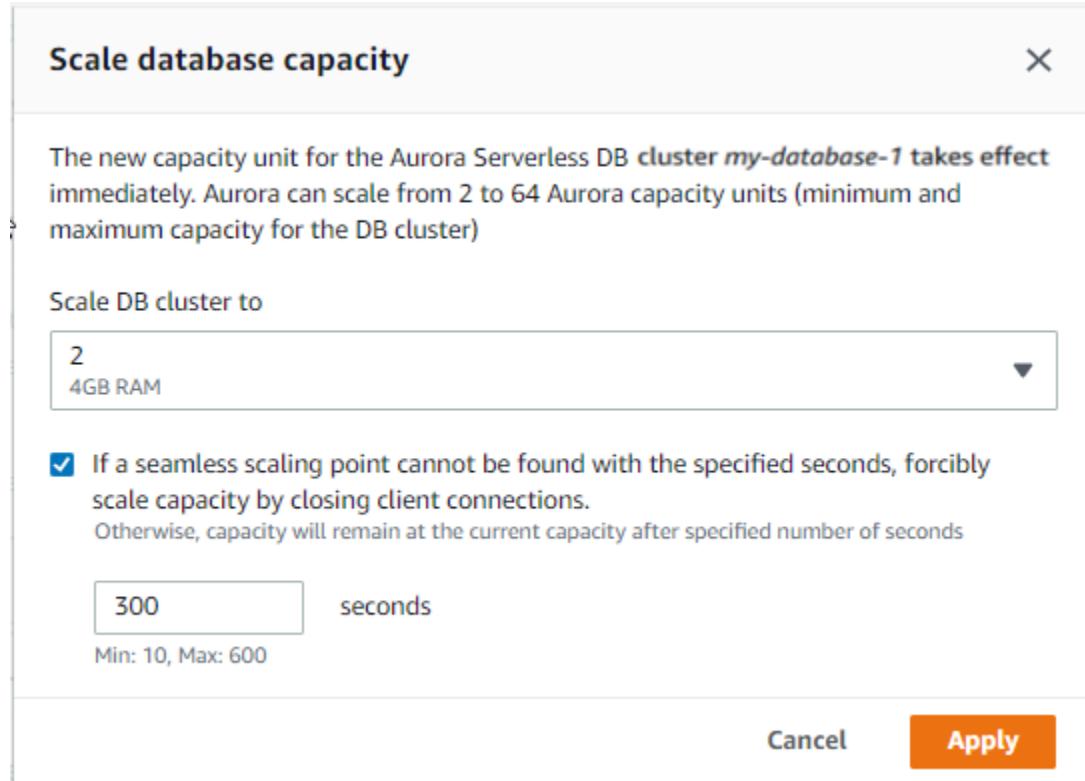

Console

You can set the capacity of an Aurora DB cluster with the AWS Management Console.

To modify an Aurora Serverless v1 DB cluster

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v1 DB cluster that you want to modify.
4. For **Actions**, choose **Set capacity**.
5. In the **Scale database capacity** window, choose the following:
 - a. For the **Scale DB cluster to** drop-down selector, choose the new capacity that you want for your DB cluster.
 - b. For the **If a seamless scaling point cannot be found...** checkbox, choose the behavior you want for your Aurora Serverless v1 DB cluster's `TimeoutAction` setting, as follows:
 - Uncheck this option if you want your capacity to remain unchanged if Aurora Serverless v1 can't find a scaling point before timing out.
 - Check this option if you want to force your Aurora Serverless v1 DB cluster change its capacity even if it can't find a scaling point before timing out. This option can result Aurora Serverless v1 dropping connections that prevent it from finding a scaling point.

- c. In the **seconds** field, enter the amount of time you want to allow your Aurora Serverless v1 DB cluster to look for a scaling point before timing out. You can specify anywhere from 60 seconds to 600 seconds (10 minutes). The default is five minutes (300 seconds). This following example forces the Aurora Serverless v1 DB cluster to scale down to 2 ACUs even if it can't find a scaling point within five minutes.

6. Choose **Apply**.

To learn more about scaling points, `TimeoutAction`, and cooldown periods, see [Autoscaling for Aurora Serverless v1 \(p. 153\)](#).

AWS CLI

To set the capacity of an Aurora Serverless v1 DB cluster using the AWS CLI, run the [modify-current-db-cluster-capacity](#) AWS CLI command, and specify the `--capacity` option. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

In this example, you set the capacity of an Aurora Serverless v1 DB cluster named `sample-cluster` to 64.

```
aws rds modify-current-db-cluster-capacity --db-cluster-identifier sample-cluster --capacity 64
```

RDS API

You can set the capacity of an Aurora DB cluster with the [ModifyCurrentDBClusterCapacity](#) API operation. Specify the **Capacity** parameter. Valid capacity values include the following:

- Aurora MySQL: 1, 2, 4, 8, 16, 32, 64, 128, and 256.
- Aurora PostgreSQL: 2, 4, 8, 16, 32, 64, 192, and 384.

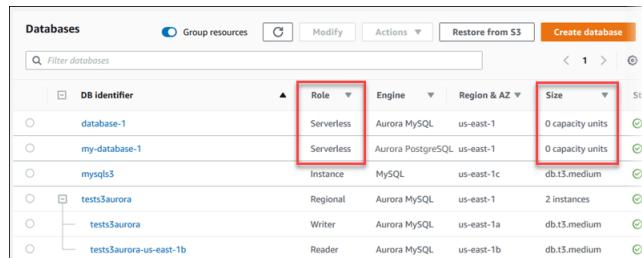

Viewing Aurora Serverless v1 DB clusters

After you create one or more Aurora Serverless v1 DB clusters, you can view which DB clusters are type **Serverless** and which are type **Instance**. You can also view the current number of Aurora capacity units (ACUs) each Aurora Serverless v1 DB cluster is using. Each ACU is a combination of processing (CPU) and memory (RAM) capacity.

To view your Aurora Serverless v1 DB clusters

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the Aurora Serverless v1 DB clusters.
3. In the navigation pane, choose **Databases**.

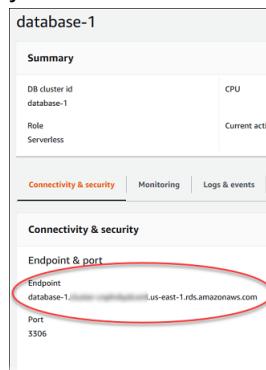

For each DB cluster, the DB cluster type is shown under **Role**. The Aurora Serverless v1 DB clusters show **Serverless** for the type. You can view an Aurora Serverless v1 DB cluster's current capacity under **Size**.

DB identifier	Role	Engine	Region & AZ	Size
database-1	Serverless	Aurora MySQL	us-east-1	0 capacity units
my-database-1	Serverless	Aurora PostgreSQL	us-east-1	0 capacity units
mysqls3	Instance	MySQL	us-east-1c	db.t3.medium
testsaurora	Regional	Aurora MySQL	us-east-1	2 instances
testsaurora	Writer	Aurora MySQL	us-east-1a	db.t3.medium
testsaurora-us-east-1b	Reader	Aurora MySQL	us-east-1b	db.t3.medium

4. Choose the name of an Aurora Serverless v1 DB cluster to display its details.

On the **Connectivity & security** tab, note the database endpoint. Use this endpoint to connect to your Aurora Serverless v1 DB cluster.

Summary	
DB cluster id	CPU
Role	Current activity

Connectivity & security	
Endpoint & port	Net:
Endpoint: database-1.us-east-1.rds.amazonaws.com	VPC: vpc-0
Port: 3306	Subnet: default
	Subnet: subn

Choose the **Configuration** tab to view the capacity settings.

Capacity settings

- Minimum Aurora capacity unit: 2 capacity units
- Maximum Aurora capacity unit: 16 capacity units
- Pause compute capacity after consecutive minutes of inactivity: 5 minutes

Force scaling the capacity to the specified values when the timeout is reached: Enabled

A *scaling event* is generated when the DB cluster scales up, scales down, pauses, or resumes. Choose the **Logs & events** tab to see recent events. The following image shows examples of these events.

Recent events (2)

Mon Aug 06 17:04:15 GMT-700 2018 The DB cluster has scaled from 8 capacity units to 4 capacity units.

Mon Aug 06 17:04:09 GMT-700 2018 Scaling DB cluster from 8 capacity units to 4 capacity units for this.

Monitoring capacity and scaling events for your Aurora Serverless v1 DB cluster

You can view your Aurora Serverless v1 DB cluster in CloudWatch to monitor the capacity allocated to the DB cluster with the `ServerlessDatabaseCapacity` metric. You can also monitor all of the standard Aurora CloudWatch metrics, such as `CPUUtilization`, `DatabaseConnections`, `Queries`, and so on.

You can have Aurora publish some or all database logs to CloudWatch. You select the logs to publish by enabling the [configuration parameters such as `general_log` and `slow_query_log` in the DB cluster parameter group \(p. 156\)](#) associated with the Aurora Serverless v1 cluster. Unlike provisioned clusters, Aurora Serverless v1 clusters don't require you to specify in the DB cluster settings which log types to upload to CloudWatch. Aurora Serverless v1 clusters automatically upload all the available logs. When you disable a log configuration parameter, publishing of the log to CloudWatch stops. You can also delete the logs in CloudWatch if they are no longer needed.

To get started with Amazon CloudWatch for your Aurora Serverless v1 DB cluster, see [Viewing Aurora Serverless v1 logs with Amazon CloudWatch \(p. 159\)](#). To learn more about how to monitor Aurora DB clusters through CloudWatch, see [Monitoring log events in Amazon CloudWatch \(p. 1020\)](#).

To connect to an Aurora Serverless v1 DB cluster, use the database endpoint. For more information, see [Connecting to an Amazon Aurora DB cluster \(p. 281\)](#).

Note

You can't connect directly to specific DB instances in your Aurora Serverless v1 DB clusters.

Deleting an Aurora Serverless v1 DB cluster

When you create an Aurora Serverless v1 DB cluster using the AWS Management Console, the **Enable default protection** option is enabled by default unless you deselect it. That means that you can't immediately delete an Aurora Serverless v1 DB cluster that has **Deletion protection** enabled. To delete Aurora Serverless v1 DB clusters that have deletion protection by using the AWS Management Console,

you first modify the cluster to remove this protection. For information about using the AWS CLI for this task, see [AWS CLI \(p. 177\)](#).

To disable deletion protection using the AWS Management Console

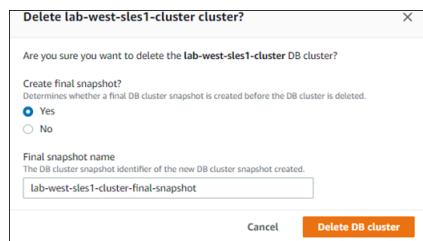

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **DB clusters**.
3. Choose your Aurora Serverless v1 DB cluster from the list.
4. Choose **Modify** to open your DB cluster's configuration. The Modify DB cluster page opens the Settings, Capacity settings, and other configuration details for your Aurora Serverless v1 DB cluster. Deletion protection is in the **Additional configuration** section.
5. Uncheck the **Enable deletion protection** option in the **Additional configuration** properties card.
6. Choose **Continue**. The **Summary of modifications** appears.
7. Choose **Modify cluster** to accept the summary of modifications. You can also choose **Back** to modify your changes or **Cancel** to discard your changes.

After deletion protection is no longer active, you can delete your Aurora Serverless v1 DB cluster by using the AWS Management Console.

Console

To delete an Aurora Serverless v1 DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the **Resources** section, choose **DB Clusters**.
3. Choose the Aurora Serverless v1 DB cluster that you want to delete.
4. For **Actions**, choose **Delete**. You're prompted to confirm that you want to delete your Aurora Serverless v1 DB cluster.
5. We recommend that you keep the preselected options:
 - **Yes for Create final snapshot?**
 - Your Aurora Serverless v1 DB cluster name plus `-final-snapshot` for **Final snapshot name**. However, you can change the name for your final snapshot in this field.

If you choose **No** for **Create final snapshot?** you can't restore your DB cluster using snapshots or point-in-time recovery.

6. Choose **Delete DB cluster**.

Aurora Serverless v1 deletes your DB cluster. If you chose to have a final snapshot, you see your Aurora Serverless v1 DB cluster's status change to "Backing-up" before it's deleted and no longer appears in the list.

AWS CLI

Before you begin, configure your AWS CLI with your AWS Access Key ID, AWS Secret Access Key, and the AWS Region where your Aurora Serverless v1 DB cluster resides. For more information, see [Configuration basics](#) in the AWS Command Line Interface User Guide.

You can't delete an Aurora Serverless v1 DB cluster until after you first disable deletion protection for clusters configured with this option. If you try to delete a cluster that has this protection option enabled, you see the following error message.

```
An error occurred (InvalidParameterCombination) when calling the DeleteDBCluster
operation: Cannot delete protected Cluster, please disable deletion protection and try
again.
```

You can change your Aurora Serverless v1 DB cluster's deletion-protection setting by using the [modify-db-cluster](#) AWS CLI command as shown in the following:

```
aws rds modify-db-cluster --db-cluster-identifier your-cluster-name --no-deletion-
protection
```

This command returns the revised properties for the specified DB cluster. You can now delete your Aurora Serverless v1 DB cluster.

We recommend that you always create a final snapshot whenever you delete an Aurora Serverless v1 DB cluster. The following example of using the AWS CLI [delete-db-cluster](#) shows you how. You provide the name of your DB cluster and a name for the snapshot.

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster --db-cluster-identifier \
your-cluster-name --no-skip-final-snapshot \
--final-db-snapshot-identifier name-your-snapshot
```

For Windows:

```
aws rds delete-db-cluster --db-cluster-identifier ^
your-cluster-name --no-skip-final-snapshot ^
--final-db-snapshot-identifier name-your-snapshot
```

Aurora Serverless v1 and Aurora database engine versions

Aurora Serverless v1 is available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For the current list of AWS Regions that support Aurora Serverless v1 and the specific Aurora MySQL and Aurora PostgreSQL versions available in each Region, see [Aurora Serverless v1 \(p. 29\)](#).

Aurora Serverless v1 uses its associated Aurora database engine to identify specific supported releases for each database engine supported, as follows:

- Aurora MySQL Serverless
- Aurora PostgreSQL Serverless

When minor releases of the database engines become available for Aurora Serverless v1, they are applied automatically in the various AWS Regions where Aurora Serverless v1 is available. In other words,

you don't need to upgrade your Aurora Serverless v1 DB cluster to get a new minor release for your cluster's DB engine when it's available for Aurora Serverless v1.

Aurora MySQL Serverless

If you want to use Aurora MySQL-Compatible Edition for your Aurora Serverless v1 DB cluster, you can choose between Aurora MySQL 5.6-compatible or Aurora MySQL 5.7-compatible versions. These two editions of Aurora MySQL differ significantly. We recommend that you compare their differences before creating your Aurora Serverless v1 DB cluster so that you make the right choice for your use case. To learn about enhancements and bug fixes for Aurora MySQL Serverless 5.6 and 5.7, see [Database engine updates for Aurora MySQL Serverless clusters \(p. 1247\)](#).

Aurora PostgreSQL Serverless

If you want to use Aurora PostgreSQL for your Aurora Serverless v1 DB cluster, you have a single version available to use. Minor releases for Aurora PostgreSQL-Compatible Edition include only changes that are backward-compatible. Your Aurora Serverless v1 DB cluster is transparently upgraded when an Aurora PostgreSQL minor release becomes available for Aurora Serverless v1 in your Region.

For example, the minor version Aurora PostgreSQL 10.14 release was transparently applied to all Aurora Serverless v1 DB clusters running the prior Aurora PostgreSQL version. For more information about the Aurora PostgreSQL version 10.14 update, see [PostgreSQL 10.14, Aurora PostgreSQL release 2.7 \(p. 1631\)](#).

Using the Data API for Aurora Serverless

By using the Data API for Aurora Serverless, you can work with a web-services interface to your Aurora Serverless DB cluster. The Data API doesn't require a persistent connection to the DB cluster. Instead, it provides a secure HTTP endpoint and integration with AWS SDKs. You can use the endpoint to run SQL statements without managing connections.

All calls to the Data API are synchronous. By default, a call times out if it's not finished processing within 45 seconds. However, you can continue running a SQL statement if the call times out by using the `continueAfterTimeout` parameter. For an example, see [Running a SQL transaction \(p. 198\)](#).

Users don't need to pass credentials with calls to the Data API, because the Data API uses database credentials stored in AWS Secrets Manager. To store credentials in Secrets Manager, users must be granted the appropriate permissions to use Secrets Manager, and also the Data API. For more information about authorizing users, see [Authorizing access to the Data API \(p. 179\)](#).

You can also use Data API to integrate Aurora Serverless with other AWS applications such as AWS Lambda, AWS AppSync, and AWS Cloud9. The API provides a more secure way to use AWS Lambda. It enables you to access your DB cluster without your needing to configure a Lambda function to access resources in a virtual private cloud (VPC). For more information, see [AWS Lambda, AWS AppSync, and AWS Cloud9](#).

You can enable the Data API when you create the Aurora Serverless cluster. You can also modify the configuration later. For more information, see [Enabling the Data API \(p. 182\)](#).

After you enable the Data API, you can also use the query editor for Aurora Serverless. For more information, see [Using the query editor for Aurora Serverless \(p. 204\)](#).

Topics

- [Data API availability \(p. 179\)](#)
- [Authorizing access to the Data API \(p. 179\)](#)
- [Enabling the Data API \(p. 182\)](#)
- [Creating an Amazon VPC endpoint for the Data API \(AWS PrivateLink\) \(p. 183\)](#)
- [Calling the Data API \(p. 186\)](#)

- [Using the Java client library for Data API \(p. 199\)](#)
- [Troubleshooting Data API issues \(p. 201\)](#)

Data API availability

The Data API can be enabled for Aurora Serverless DB clusters using specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see [Data API for Aurora Serverless \(p. 31\)](#).

The following table shows the AWS Regions where the Data API is currently available for Aurora Serverless. To access the Data API in these Regions, use the HTTPS protocol.

Region	Link
US East (Ohio)	rds-data.us-east-2.amazonaws.com
US East (N. Virginia)	rds-data.us-east-1.amazonaws.com
US West (N. California)	rds-data.us-west-1.amazonaws.com
US West (Oregon)	rds-data.us-west-2.amazonaws.com
Asia Pacific (Mumbai)	rds-data.ap-south-1.amazonaws.com
Asia Pacific (Seoul)	rds-data.ap-northeast-2.amazonaws.com
Asia Pacific (Singapore)	rds-data.ap-southeast-1.amazonaws.com
Asia Pacific (Sydney)	rds-data.ap-southeast-2.amazonaws.com
Asia Pacific (Tokyo)	rds-data.ap-northeast-1.amazonaws.com
Canada (Central)	rds-data.ca-central-1.amazonaws.com
Europe (Frankfurt)	rds-data.eu-central-1.amazonaws.com
Europe (Ireland)	rds-data.eu-west-1.amazonaws.com
Europe (London)	rds-data.eu-west-2.amazonaws.com
Europe (Paris)	rds-data.eu-west-3.amazonaws.com

If you require cryptographic modules validated by FIPS 140-2 when accessing the Data API through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-2](#).

Authorizing access to the Data API

Users can invoke Data API operations only if they are authorized to do so. You can give a user permission to use the Data API by attaching an AWS Identity and Access Management (IAM) policy that defines their privileges. You can also attach the policy to a role if you're using IAM roles. An AWS managed policy, `AmazonRDSDataFullAccess`, includes permissions for the RDS Data API.

The `AmazonRDSDataFullAccess` policy also includes permissions for the user to get the value of a secret from AWS Secrets Manager. Users need to use Secrets Manager to store secrets that they can use in their calls to the Data API. Using secrets means that users don't need to include database credentials for the resources that they target in their calls to the Data API. The Data API transparently calls Secrets Manager, which allows (or denies) the user's request for the secret. For information about setting up secrets to use with the Data API, see [Storing database credentials in AWS Secrets Manager \(p. 181\)](#).

The `AmazonRDSDataFullAccess` policy provides complete access (through the Data API) to resources. You can narrow the scope by defining your own policies that specify the Amazon Resource Name (ARN) of a resource.

For example, the following policy shows an example of the minimum required permissions for a user to access the Data API for the DB cluster identified by its ARN. The policy includes the needed permissions to access Secrets Manager and get authorization to the DB instance for the user.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "SecretsManagerDbCredentialsAccess",  
            "Effect": "Allow",  
            "Action": [  
                "secretsmanager:GetSecretValue"  
            ],  
            "Resource": "arn:aws:secretsmanager:*::secret:rds-db-credentials/*"  
        },  
        {  
            "Sid": "RDSDataserviceAccess",  
            "Effect": "Allow",  
            "Action": [  
                "rds-data:BatchExecuteStatement",  
                "rds-data:BeginTransaction",  
                "rds-data:CommitTransaction",  
                "rds-data:ExecuteStatement",  
                "rds-data:RollbackTransaction"  
            ],  
            "Resource": "arn:aws:rds:us-east-2:111122223333:cluster:prod"  
        }  
    ]  
}
```

We recommend that you use a specific ARN for the "Resources" element in your policy statements (as shown in the example) rather than a wildcard (*).

Working with tag-based authorization

The Data API and Secrets Manager both support tag-based authorization. *Tags* are key-value pairs that label a resource, such as an RDS cluster, with an additional string value, for example:

- `environment:production`
- `environment:development`

You can apply tags to your resources for cost allocation, operations support, access control, and many other reasons. (If you don't already have tags on your resources and you want to apply them, you can learn more at [Tagging Amazon RDS resources](#).) You can use the tags in your policy statements to limit access to the RDS clusters that are labeled with these tags. As an example, an Aurora DB cluster might have tags that identify its environment as either production or development.

The following example shows how you can use tags in your policy statements. This statement requires that both the cluster and the secret passed in the Data API request have an `environment:production` tag.

Here's how the policy gets applied: When a user makes a call using the Data API, the request is sent to the service. The Data API first verifies that the cluster ARN passed in the request is tagged with `environment:production`. It then calls Secrets Manager to retrieve the value of the user's secret in the request. Secrets Manager also verifies that the user's secret is tagged with

`environment:production`. If so, Data API then uses the retrieved value for the user's DB password. Finally, if that's also correct, the Data API request is invoked successfully for the user.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SecretsManagerDbCredentialsAccess",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue"
            ],
            "Resource": "arn:aws:secretsmanager:*::secret:rds-db-credentials/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/environment": [
                        "production"
                    ]
                }
            }
        },
        {
            "Sid": "RDSDataServiceAccess",
            "Effect": "Allow",
            "Action": [
                "rds-data:*
```

The example shows separate actions for `rds-data` and `secretsmanager` for the Data API and Secrets Manager. However, you can combine actions and define tag conditions in many different ways to support your specific use cases. For more information, see [Using identity-based policies \(IAM policies\) for Secrets Manager](#).

In the "Condition" element of the policy, you can choose tag keys from among the following:

- `aws:TagKeys`
- `aws:ResourceTag/${TagKey}`

To learn more about resource tags and how to use `aws:TagKeys`, see [Controlling access to AWS resources using resource tags](#).

Note

Both the Data API and AWS Secrets Manager authorize users. If you don't have permissions for all actions defined in a policy, you get an `AccessDeniedException` error.

Storing database credentials in AWS Secrets Manager

When you call the Data API, you can pass credentials for the Aurora Serverless DB cluster by using a secret in Secrets Manager. To pass credentials in this way, you specify the name of the secret or the Amazon Resource Name (ARN) of the secret.

To store DB cluster credentials in a secret

1. Use Secrets Manager to create a secret that contains credentials for the Aurora DB cluster.
For instructions, see [Creating a Basic Secret](#) in the *AWS Secrets Manager User Guide*.
2. Use the Secrets Manager console to view the details for the secret you created, or run the `aws secretsmanager describe-secret` AWS CLI command.

Note the name and ARN of the secret. You can use them in calls to the Data API.

For more information about using Secrets Manager, see the [AWS Secrets Manager User Guide](#).

To understand how Amazon Aurora manages identity and access management, see [How Amazon Aurora works with IAM](#).

For more information about creating an IAM policy, see [Creating IAM Policies](#) in the *IAM User Guide*. For information about adding an IAM policy to a user, see [Adding and Removing IAM Identity Permissions](#) in the *IAM User Guide*.

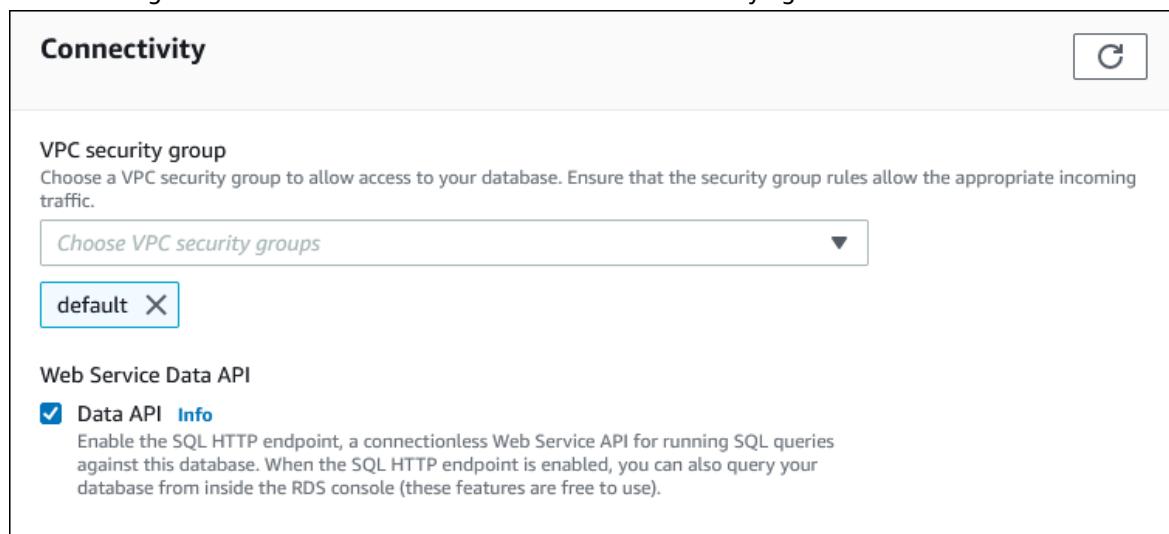

Enabling the Data API

To use the Data API, enable it for your Aurora Serverless DB cluster. You can enable the Data API when you create or modify the DB cluster.

Console

You can enable the Data API by using the RDS console when you create or modify an Aurora Serverless DB cluster. When you create or modify an Aurora Serverless DB cluster, you do so by enabling the Data API in the RDS console's **Connectivity** section.

The following screenshot shows the enabled **Data API** when modifying an Aurora Serverless DB cluster.

For instructions, see [Creating an Aurora Serverless v1 DB cluster \(p. 161\)](#) and [Modifying an Aurora Serverless v1 DB cluster \(p. 170\)](#).

AWS CLI

When you create or modify an Aurora Serverless DB cluster using AWS CLI commands, the Data API is enabled when you specify `--enable-http-endpoint`.

You can specify the `--enable-http-endpoint` using the following AWS CLI commands:

- [create-db-cluster](#)
- [modify-db-cluster](#)

The following example modifies `sample-cluster` to enable the Data API.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
  --db-cluster-identifier sample-cluster \
  --enable-http-endpoint
```

For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier sample-cluster ^
  --enable-http-endpoint
```

RDS API

When you create or modify an Aurora Serverless DB cluster using Amazon RDS API operations, you enable the Data API by setting the `EnableHttpEndpoint` value to `true`.

You can set the `EnableHttpEndpoint` value using the following API operations:

- [CreateDBCluster](#)
- [ModifyDBCluster](#)

Creating an Amazon VPC endpoint for the Data API (AWS PrivateLink)

Amazon VPC enables you to launch AWS resources, such as Aurora DB clusters and applications, into a virtual private cloud (VPC). AWS PrivateLink provides private connectivity between VPCs and AWS services with high security on the Amazon network. Using AWS PrivateLink, you can create Amazon VPC endpoints, which enable you to connect to services across different accounts and VPCs based on Amazon VPC. For more information about AWS PrivateLink, see [VPC Endpoint Services \(AWS PrivateLink\)](#) in the [Amazon Virtual Private Cloud User Guide](#).

You can call the Data API with Amazon VPC endpoints. Using an Amazon VPC endpoint keeps traffic between applications in your Amazon VPC and the Data API in the AWS network, without using public IP addresses. Amazon VPC endpoints can help you meet compliance and regulatory requirements related to limiting public internet connectivity. For example, if you use an Amazon VPC endpoint, you can keep traffic between an application running on an Amazon EC2 instance and the Data API in the VPCs that contain them.

After you create the Amazon VPC endpoint, you can start using it without making any code or configuration changes in your application.

To create an Amazon VPC endpoint for the Data API

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.

2. Choose **Endpoints**, and then choose **Create Endpoint**.
3. On the **Create Endpoint** page, for **Service category**, choose **AWS services**. For **Service Name**, choose **rds-data**.

The screenshot shows the 'Create Endpoint' wizard. In the 'Service category' section, 'AWS services' is selected. In the 'Service Name' field, 'com.amazonaws.eu-west-1.rds-data' is entered. Below this, a search results table lists various AWS services, with 'com.amazonaws.eu-west-1.rds-data' highlighted by a red box.

Service Name	Owner	Type
com.amazonaws.eu-west-1.elastic-infer...	amazon	Interface
com.amazonaws.eu-west-1.elasticfilesystem	amazon	Interface
com.amazonaws.eu-west-1.elasticfilesystem...	amazon	Interface
com.amazonaws.eu-west-1.elasticloadbal...	amazon	Interface
com.amazonaws.eu-west-1.elasticmapred...	amazon	Interface
com.amazonaws.eu-west-1.events	amazon	Interface
com.amazonaws.eu-west-1.execute-api	amazon	Interface
com.amazonaws.eu-west-1.glue	amazon	Interface
com.amazonaws.eu-west-1.kinesis-firehose	amazon	Interface
com.amazonaws.eu-west-1.kinesis-streams	amazon	Interface
com.amazonaws.eu-west-1.logs	amazon	Interface
com.amazonaws.eu-west-1.rds-data	amazon	Interface
com.amazonaws.eu-west-1.rekognition	amazon	Interface
com.amazonaws.eu-west-1.s3	amazon	Gateway

4. For **VPC**, choose the VPC to create the endpoint in.

Choose the VPC that contains the application that makes Data API calls.

5. For **Subnets**, choose the subnet for each Availability Zone (AZ) used by the AWS service that is running your application.

The screenshot shows the 'Subnets' configuration section. A VPC is selected ('vpc-c20d2da4'). Three subnets are listed: 'subnet-2c8ee364' (eu-west-1a), 'subnet-cefa2594' (eu-west-1b), and 'subnet-20c45946' (eu-west-1c). Each subnet is associated with a specific Availability Zone.

Availability Zone	Subnet ID
eu-west-1a (euw1-az2)	subnet-2c8ee364
eu-west-1b (euw1-az3)	subnet-cefa2594
eu-west-1c (euw1-az1)	subnet-20c45946

To create an Amazon VPC endpoint, specify the private IP address range in which the endpoint will be accessible. To do this, choose the subnet for each Availability Zone. Doing so restricts the VPC endpoint to the private IP address range specific to each Availability Zone and also creates an Amazon VPC endpoint in each Availability Zone.

6. For **Enable DNS name**, select **Enable for this endpoint**.

The screenshot shows the 'Enable DNS name' configuration section. A checkbox is checked for 'Enable for this endpoint'. A note below states: 'To use private DNS names, ensure that the attributes 'Enable DNS hostnames' and 'Enable DNS Support' are set to 'true' for your VPC (vpc-c20d2da4). Learn more.'

Private DNS resolves the standard Data API DNS hostname (<https://rds-data.region.amazonaws.com>) to the private IP addresses associated with the DNS hostname

specific to your Amazon VPC endpoint. As a result, you can access the Data API VPC endpoint using the AWS CLI or AWS SDKs without making any code or configuration changes to update the Data API endpoint URL.

7. For **Security group**, choose a security group to associate with the Amazon VPC endpoint.

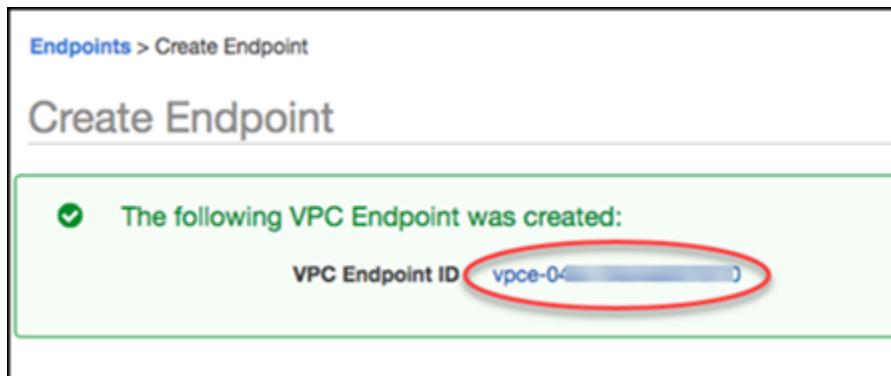

Choose the security group that allows access to the AWS service that is running your application. For example, if an Amazon EC2 instance is running your application, choose the security group that allows access to the Amazon EC2 instance. The security group enables you to control the traffic to the Amazon VPC endpoint from resources in your VPC.

8. For **Policy**, choose **Full Access** to allow anyone inside the Amazon VPC to access the Data API through this endpoint. Or choose **Custom** to specify a policy that limits access.

If you choose **Custom**, enter the policy in the policy creation tool.

9. Choose **Create endpoint**.

After the endpoint is created, choose the link in the AWS Management Console to view the endpoint details.

The endpoint **Details** tab shows the DNS hostnames that were generated while creating the Amazon VPC endpoint.

Endpoint: vpce-04ec15ecbab57bf10							
		Details	Subnets	Security Groups	Policy	Notifications	Tags
Endpoint ID	vpce-04ec15ecbab57bf10	VPC ID	vpce-04ec15ecbab57bf10				
Status	available	Status message					
Creation time	January 31, 2020 at 7:02:32 PM UTC-8	Service name	com.amazonaws.eu-west-1.rds-data				
Endpoint type	Interface	DNS names	vpce-04ec15ecbab57bf10.vpc.amazonaws.com	(redacted)	(redacted)	(redacted)	(redacted)
			vpce-04ec15ecbab57bf10.eu-west-1b.rds-data.eu-west-1.vpc.amazonaws.com	(redacted)	(redacted)	(redacted)	(redacted)
			vpce-04ec15ecbab57bf10.eu-west-1c.rds-data.eu-west-1.vpc.amazonaws.com	(redacted)	(redacted)	(redacted)	(redacted)
			vpce-04ec15ecbab57bf10.eu-west-1a.rds-data.eu-west-1.vpc.amazonaws.com	(redacted)	(redacted)	(redacted)	(redacted)
			rds-data.eu-west-1.amazonaws.com	(redacted)	(redacted)	(redacted)	(redacted)
Private DNS names enabled	true	Private DNS name	rds-data.eu-west-1.amazonaws.com				

You can use the standard endpoint (`rds-data.region.amazonaws.com`) or one of the VPC-specific endpoints to call the Data API within the Amazon VPC. The standard Data API endpoint automatically routes to the Amazon VPC endpoint. This routing occurs because the Private DNS hostname was enabled when the Amazon VPC endpoint was created.

When you use an Amazon VPC endpoint in a Data API call, all traffic between your application and the Data API remains in the Amazon VPCs that contain them. You can use an Amazon VPC endpoint for any type of Data API call. For information about calling the Data API, see [Calling the Data API \(p. 186\)](#).

Calling the Data API

With the Data API enabled on your Aurora Serverless DB cluster, you can run SQL statements on the Aurora DB cluster by using the Data API or the AWS CLI. The Data API supports the programming languages supported by the AWS SDKs. For more information, see [Tools to build on AWS](#).

Note

Currently, the Data API doesn't support arrays of Universal Unique Identifiers (UUIDs).

The Data API provides the following operations to perform SQL statements.

Data API operation	AWS CLI command	Description
<code>ExecuteStatement</code>	<code>rds-data execute-statement</code>	Runs a SQL statement on a database.
<code>BatchExecuteStatement</code>	<code>rds-data batch-execute-statement</code>	Runs a batch SQL statement over an array of data for bulk update and insert operations. You can run a data manipulation language (DML) statement with an array of parameter sets. A batch SQL statement can provide a significant performance improvement over individual insert and update statements.

You can use either operation to run individual SQL statements or to run transactions. For transactions, the Data API provides the following operations.

Data API operation	AWS CLI command	Description
<code>BeginTransaction</code>	<code>rds-data begin-transaction</code>	Starts a SQL transaction.
<code>CommitTransaction</code>	<code>rds-data commit-transaction</code>	Ends a SQL transaction and commits the changes.
<code>RollbackTransaction</code>	<code>rds-data rollback-transaction</code>	Performs a rollback of a transaction.

The operations for performing SQL statements and supporting transactions have the following common Data API parameters and AWS CLI options. Some operations support other parameters or options.

Data API operation parameter	AWS CLI command option	Required	Description
<code>resourceArn</code>	<code>--resource-arn</code>	Yes	The Amazon Resource Name (ARN) of the Aurora Serverless DB cluster.
<code>secretArn</code>	<code>--secret-arn</code>	Yes	The name or ARN of the secret that enables access to the DB cluster.

You can use parameters in Data API calls to `ExecuteStatement` and `BatchExecuteStatement`, and when you run the AWS CLI commands `execute-statement` and `batch-execute-statement`. To use

a parameter, you specify a name-value pair in the `SqlParameter` data type. You specify the value with the `Field` data type. The following table maps Java Database Connectivity (JDBC) data types to the data types that you specify in Data API calls.

JDBC data type	Data API data type
INTEGER, TINYINT, SMALLINT, BIGINT	LONG (or STRING)
FLOAT, REAL, DOUBLE	DOUBLE
DECIMAL	STRING
BOOLEAN, BIT	BOOLEAN
BLOB, BINARY, LONGVARBINARY, VARBINARY	BLOB
CLOB	STRING
Other types (including types related to date and time)	STRING

Note

You can specify the `LONG` or `STRING` data type in your Data API call for `LONG` values returned by the database. We recommend that you do so to avoid losing precision for extremely large numbers, which can happen when you work with JavaScript.

Certain types, such as `DECIMAL` and `TIME`, require a hint so that the Data API passes `String` values to the database as the correct type. To use a hint, include values for `typeHint` in the `SqlParameter` data type. The possible values for `typeHint` are the following:

- `DATE` – The corresponding `String` parameter value is sent as an object of `DATE` type to the database. The accepted format is `YYYY-MM-DD`.
- `DECIMAL` – The corresponding `String` parameter value is sent as an object of `DECIMAL` type to the database.
- `JSON` – The corresponding `String` parameter value is sent as an object of `JSON` type to the database.
- `TIME` – The corresponding `String` parameter value is sent as an object of `TIME` type to the database. The accepted format is `HH:MM:SS[.FFF]`.
- `TIMESTAMP` – The corresponding `String` parameter value is sent as an object of `TIMESTAMP` type to the database. The accepted format is `YYYY-MM-DD HH:MM:SS[.FFF]`.
- `UUID` – The corresponding `String` parameter value is sent as an object of `UUID` type to the database.

Note

For Amazon Aurora PostgreSQL, the Data API always returns the Aurora PostgreSQL data type `TIMESTAMPTZ` in UTC time zone.

Calling the Data API with the AWS CLI

You can call the Data API using the AWS CLI.

The following examples use the AWS CLI for the Data API. For more information, see [AWS CLI reference for the Data API](#).

In each example, replace the Amazon Resource Name (ARN) for the DB cluster with the ARN for your Aurora Serverless DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

Note

The AWS CLI can format responses in JSON.

Topics

- [Starting a SQL transaction \(p. 188\)](#)
- [Running a SQL statement \(p. 188\)](#)
- [Running a batch SQL statement over an array of data \(p. 191\)](#)
- [Committing a SQL transaction \(p. 193\)](#)
- [Rolling back a SQL transaction \(p. 193\)](#)

Starting a SQL transaction

You can start a SQL transaction using the `aws rds-data begin-transaction` CLI command. The call returns a transaction identifier.

Important

A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.

Data definition language (DDL) statements inside a transaction cause an implicit commit. We recommend that you run each DDL statement in a separate `execute-statement` command with the `--continue-after-timeout` option.

In addition to the common options, specify the `--database` option, which provides the name of the database.

For example, the following CLI command starts a SQL transaction.

For Linux, macOS, or Unix:

```
aws rds-data begin-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret"
```

For Windows:

```
aws rds-data begin-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret"
```

The following is an example of the response.

```
{  
    "transactionId": "ABC1234567890xyz"  
}
```

Running a SQL statement

You can run a SQL statement using the `aws rds-data execute-statement` CLI command.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction using the `aws rds-data commit-transaction` CLI command.

Important

If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.
- `--transaction-id` (optional) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
- `--parameters` (optional) – The parameters for the SQL statement.
- `--include-result-metadata` | `--no-include-result-metadata` (optional) – A value that indicates whether to include metadata in the results. The default is `--no-include-result-metadata`.
- `--database` (optional) – The name of the database.
- `--continue-after-timeout` | `--no-continue-after-timeout` (optional) – A value that indicates whether to continue running the statement after the call times out. The default is `--no-continue-after-timeout`.

For data definition language (DDL) statements, we recommend continuing to run the statement after the call times out to avoid errors and the possibility of corrupted data structures.

The DB cluster returns a response for the call.

Note

The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.

The maximum number of requests per second is 1,000.

For example, the following CLI command runs a single SQL statement and omits the metadata in the results (the default).

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "select * from mytable"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "select * from mytable"
```

The following is an example of the response.

```
{
    "numberOfRecordsUpdated": 0,
    "records": [
        [
            {
                "longValue": 1
            }
        ]
    ]
}
```

```

        },
        {
            "stringValue": "ValueOne"
        }
    ],
    [
        {
            "longValue": 2
        },
        {
            "stringValue": "ValueTwo"
        }
    ],
    [
        {
            "longValue": 3
        },
        {
            "stringValue": "ValueThree"
        }
    ]
}

```

The following CLI command runs a single SQL statement in a transaction by specifying the --transaction-id option.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "update mytable set quantity=5 where id=201" --transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "update mytable set quantity=5 where id=201" --transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{
    "numberOfRecordsUpdated": 1
}
```

The following CLI command runs a single SQL statement with parameters.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "insert into mytable values (:id, :val)" --parameters "[{\\"name\\": \"id\", \\"value\\": \\"longValue\\": 1}, {\\"name\\": \"val\", \\"value\\": {\"stringValue\": \"value1\"}}]"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "insert into mytable values (:id, :val)" --parameters "[{"name": "\id", "value": "\longValue": 1}, {"name": "\val", "value": {"stringValue": "\value1"}}]"
```

The following is an example of the response.

```
{  
    "numberOfRecordsUpdated": 1  
}
```

The following CLI command runs a data definition language (DDL) SQL statement. The DDL statement renames column `job` to column `role`.

Important

For DDL statements, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call times out, specify the `--continue-after-timeout` option.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "alter table mytable change column job role varchar(100)" --continue-after-timeout
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--sql "alter table mytable change column job role varchar(100)" --continue-after-timeout
```

The following is an example of the response.

```
{  
    "generatedFields": [],  
    "numberOfRecordsUpdated": 0  
}
```

Note

The `generatedFields` data isn't supported by Aurora PostgreSQL. To get the values of generated fields, use the `RETURNING` clause. For more information, see [Returning data from modified rows](#) in the PostgreSQL documentation.

Running a batch SQL statement over an array of data

You can run a batch SQL statement over an array of data by using the `aws rds-data batch-execute-statement` CLI command. You can use this command to perform a bulk import or update operation.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction by using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction by using the `aws rds-data commit-transaction` CLI command.

Important

If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.

Tip

For MySQL-compatible statements, don't include a semicolon at the end of the `--sql` parameter. A trailing semicolon might cause a syntax error.

- `--transaction-id` (optional) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
- `--parameter-set` (optional) – The parameter sets for the batch operation.
- `--database` (optional) – The name of the database.

The DB cluster returns a response to the call.

Note

There isn't a fixed upper limit on the number of parameter sets. However, the maximum size of the HTTP request submitted through the Data API is 4 MiB. If the request exceeds this limit, the Data API returns an error and doesn't process the request. This 4 MiB limit includes the size of the HTTP headers and the JSON notation in the request. Thus, the number of parameter sets that you can include depends on a combination of factors, such as the size of the SQL statement and the size of each parameter set.

The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.

The maximum number of requests per second is 1,000.

For example, the following CLI command runs a batch SQL statement over an array of data with a parameter set.

For Linux, macOS, or Unix:

```
aws rds-data batch-execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--sql "insert into mytable values (:id, :val)" \
--parameter-sets "[[{"name": "\id", "value": {"longValue": 1}}, {"name": "\val", "value": {"stringValue": "ValueOne"}}, {"name": "\id", "value": {"longValue": 2}}, {"name": "\val", "value": {"stringValue": "ValueTwo"}}, {"name": "\id", "value": {"longValue": 3}}, {"name": "\val", "value": {"stringValue": "ValueThree"}}]]"
```

For Windows:

```
aws rds-data batch-execute-statement --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--database "mydb" --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
```

```
--sql "insert into mytable values (:id, :val)" ^
--parameter-sets "[[{"name": "\$id", "value": {"longValue": 1}}, {"name": "\$val",
  "value": {"stringValue": "ValueOne"}}], [{"name": "\$id", "value": {"longValue": 2}}, {"name": "\$val", "value": {"stringValue": "ValueTwo"}}], [{"name": "\$id", "value": {"longValue": 3}}, {"name": "\$val", "value": {"stringValue": "ValueThree"}}]]"
```

Note

Don't include line breaks in the --parameter-sets option.

Committing a SQL transaction

Using the aws rds-data commit-transaction CLI command, you can end a SQL transaction that you started with aws rds-data begin-transaction and commit the changes.

In addition to the common options, specify the following option:

- **--transaction-id** (required) – The identifier of a transaction that was started using the begin-transaction CLI command. Specify the transaction ID of the transaction that you want to end and commit.

For example, the following CLI command ends a SQL transaction and commits the changes.

For Linux, macOS, or Unix:

```
aws rds-data commit-transaction --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" \
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data commit-transaction --resource-arn "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{  
    "transactionStatus": "Transaction Committed"  
}
```

Rolling back a SQL transaction

Using the aws rds-data rollback-transaction CLI command, you can roll back a SQL transaction that you started with aws rds-data begin-transaction. Rolling back a transaction cancels its changes.

Important

If the transaction ID has expired, the transaction was rolled back automatically. In this case, an aws rds-data rollback-transaction command that specifies the expired transaction ID returns an error.

In addition to the common options, specify the following option:

- **--transaction-id** (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to roll back.

For example, the following AWS CLI command rolls back a SQL transaction.

For Linux, macOS, or Unix:

```
aws rds-data rollback-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" \
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" \
--transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data rollback-transaction --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster" ^
--secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
--transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{  
    "transactionStatus": "Rollback Complete"  
}
```

Calling the Data API from a Python application

You can call the Data API from a Python application.

The following examples use the AWS SDK for Python (Boto). For more information about Boto, see the [AWS SDK for Python \(Boto 3\) documentation](#).

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora Serverless DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

Topics

- [Running a SQL query \(p. 194\)](#)
- [Running a DML SQL statement \(p. 195\)](#)
- [Running a SQL transaction \(p. 196\)](#)

Running a SQL query

You can run a `SELECT` statement and fetch the results with a Python application.

The following example runs a SQL query.

```
import boto3  
  
rdsData = boto3.client('rds-data')  
  
cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'  
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'  
  
response1 = rdsData.execute_statement(  
    resourceArn = cluster_arn,  
    secretArn = secret_arn,
```

```
        database = 'mydb',
        sql = 'select * from employees limit 3')

print (response1['records'])
[
    [
        {
            'longValue': 1
        },
        {
            'stringValue': 'ROSALEZ'
        },
        {
            'stringValue': 'ALEJANDRO'
        },
        {
            'stringValue': '2016-02-15 04:34:33.0'
        }
    ],
    [
        {
            'longValue': 1
        },
        {
            'stringValue': 'DOE'
        },
        {
            'stringValue': 'JANE'
        },
        {
            'stringValue': '2014-05-09 04:34:33.0'
        }
    ],
    [
        {
            'longValue': 1
        },
        {
            'stringValue': 'STILES'
        },
        {
            'stringValue': 'JOHN'
        },
        {
            'stringValue': '2017-09-20 04:34:33.0'
        }
    ]
]
```

Running a DML SQL statement

You can run a data manipulation language (DML) statement to insert, update, or delete data in your database. You can also use parameters in DML statements.

Important

If a call isn't part of a transaction because it doesn't include the `transactionID` parameter, changes that result from the call are committed automatically.

The following example runs an insert SQL statement and uses parameters.

```
import boto3

cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'
```

```
rdsData = boto3.client('rds-data')

param1 = {'name':'firstname', 'value':{'stringValue': 'JACKSON'}}
param2 = {'name':'lastname', 'value':{'stringValue': 'MATEO'}}
paramSet = [param1, param2]

response2 = rdsData.execute_statement(resourceArn=cluster_arn,
                                      secretArn=secret_arn,
                                      database='mydb',
                                      sql='insert into employees(first_name, last_name)
VALUES(:firstname, :lastname)',
                                      parameters = paramSet)

print (response2["numberOfRecordsUpdated"])
```

Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Python application.

Important

A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.
If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction that inserts a row in a table.

```
import boto3

rdsData = boto3.client('rds-data')

cluster_arn = 'arn:aws:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws:secretsmanager:us-east-1:123456789012:secret:mysecret'

tr = rdsData.begin_transaction(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb')

response3 = rdsData.execute_statement(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    database = 'mydb',
    sql = 'insert into employees(first_name, last_name) values('XIULAN', 'WANG')',
    transactionId = tr['transactionId'])

cr = rdsData.commit_transaction(
    resourceArn = cluster_arn,
    secretArn = secret_arn,
    transactionId = tr['transactionId'])

cr['transactionStatus']
'Transaction Committed'

response3['numberOfRecordsUpdated']
1
```

Note

If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished

running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call times out, set the `continueAfterTimeout` parameter to `true`.

Calling the Data API from a Java application

You can call the Data API from a Java application.

The following examples use the AWS SDK for Java. For more information, see the [AWS SDK for Java Developer Guide](#).

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora Serverless DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

Topics

- [Running a SQL query \(p. 197\)](#)
- [Running a SQL transaction \(p. 198\)](#)
- [Running a batch SQL operation \(p. 198\)](#)

Running a SQL query

You can run a `SELECT` statement and fetch the results with a Java application.

The following example runs a SQL query.

```
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;
import com.amazonaws.services.rdsdata.model.ExecuteStatementResult;
import com.amazonaws.services.rdsdata.model.Field;

import java.util.List;

public class FetchResultsExample {
    public static final String RESOURCE_ARN = "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster";
    public static final String SECRET_ARN = "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        ExecuteStatementRequest request = new ExecuteStatementRequest()
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withDatabase("mydb")
            .withSql("select * from mytable");

        ExecuteStatementResult result = rdsData.executeStatement(request);

        for (List<Field> fields: result.getRecords()) {
            String stringValue = fields.get(0).getStringValue();
            long numberValue = fields.get(1).getLongValue();

            System.out.println(String.format("Fetched row: string = %s, number = %d",
                stringValue, numberValue));
        }
    }
}
```

Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Java application.

Important

A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.
If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction.

```
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.BeginTransactionRequest;
import com.amazonaws.services.rdsdata.model.BeginTransactionResult;
import com.amazonaws.services.rdsdata.model.CommitTransactionRequest;
import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;

public class TransactionExample {
    public static final String RESOURCE_ARN = "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster";
    public static final String SECRET_ARN = "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        BeginTransactionRequest beginTransactionRequest = new BeginTransactionRequest()
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withDatabase("mydb");
        BeginTransactionResult beginTransactionResult =
        rdsData.beginTransaction(beginTransactionRequest);
        String transactionId = beginTransactionResult.getTransactionId();

        ExecuteStatementRequest executeStatementRequest = new ExecuteStatementRequest()
            .withTransactionId(transactionId)
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withSql("INSERT INTO test_table VALUES ('hello world!')");
        rdsData.executeStatement(executeStatementRequest);

        CommitTransactionRequest commitTransactionRequest = new CommitTransactionRequest()
            .withTransactionId(transactionId)
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN);
        rdsData.commitTransaction(commitTransactionRequest);
    }
}
```

Note

If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call times out, set the `continueAfterTimeout` parameter to `true`.

Running a batch SQL operation

You can run bulk insert and update operations over an array of data with a Java application. You can run a DML statement with array of parameter sets.

Important

If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a batch insert operation.

```
package com.amazonaws.rdsdata.examples;

import com.amazonaws.services.rdsdata.AWSRDSData;
import com.amazonaws.services.rdsdata.AWSRDSDataClient;
import com.amazonaws.services.rdsdata.model.BatchExecuteStatementRequest;
import com.amazonaws.services.rdsdata.model.Field;
import com.amazonaws.services.rdsdata.model.SqlParameter;

import java.util.Arrays;

public class BatchExecuteExample {
    public static final String RESOURCE_ARN = "arn:aws:rds:us-
east-1:123456789012:cluster:mydbcluster";
    public static final String SECRET_ARN = "arn:aws:secretsmanager:us-
east-1:123456789012:secret:mysecret";

    public static void main(String[] args) {
        AWSRDSData rdsData = AWSRDSDataClient.builder().build();

        BatchExecuteStatementRequest request = new BatchExecuteStatementRequest()
            .withDatabase("test")
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withSql("INSERT INTO test_table2 VALUES (:string, :number)")
            .withParameterSets(Arrays.asList(
                Arrays.asList(
                    new SqlParameter().withName("string").WithValue(new
Field().withStringValue("Hello")),
                    new SqlParameter().withName("number").WithValue(new
Field().withLongValue(1L))
                ),
                Arrays.asList(
                    new SqlParameter().withName("string").WithValue(new
Field().withStringValue("World")),
                    new SqlParameter().withName("number").WithValue(new
Field().withLongValue(2L))
                )
            ));
        rdsData.batchExecuteStatement(request);
    }
}
```

Using the Java client library for Data API

You can download and use a Java client library for the Data API. This Java client library provides an alternative way to use the Data API. Using this library, you can map your client-side classes to requests and responses of the Data API. This mapping support can ease integration with some specific Java types, such as Date, Time, and BigDecimal.

Downloading the Java client library for Data API

The Data API Java client library is open source in GitHub at the following location:

<https://github.com/awslabs/rds-data-api-client-library-java>

You can build the library manually from the source files, but the best practice is to consume the library using Apache Maven dependency management. Add the following dependency to your Maven POM file.

For version 2.x, which is compatible with AWS SDK 2.x, use the following:

```
<dependency>
    <groupId>software.amazon.rdsdata</groupId>
    <artifactId>rds-data-api-client-library-java</artifactId>
    <version>2.0.0</version>
</dependency>
```

For version 1.x, which is compatible with AWS SDK 1.x, use the following:

```
<dependency>
    <groupId>software.amazon.rdsdata</groupId>
    <artifactId>rds-data-api-client-library-java</artifactId>
    <version>1.0.8</version>
</dependency>
```

Java client library examples

Following, you can find some common examples of using the Data API Java client library. These examples assume that you have a table accounts with two columns: accountID and name. You also have the following data transfer object (DTO).

```
public class Account {
    int accountId;
    String name;
    // getters and setters omitted
}
```

The client library enables you to pass DTOs as input parameters. The following example shows how customer DTOs are mapped to input parameters sets.

```
var account1 = new Account(1, "John");
var account2 = new Account(2, "Mary");
client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)")
    .withParamSets(account1, account2)
    .execute();
```

In some cases, it's easier to work with simple values as input parameters. You can do so with the following syntax.

```
client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)")
    .withParameter("accountId", 3)
    .withParameter("name", "Zhang")
    .execute();
```

The following is another example that works with simple values as input parameters.

```
client.forSql("INSERT INTO accounts(accountId, name) VALUES(?, ?)", 4, "Carlos")
    .execute();
```

The client library provides automatic mapping to DTOs when a result is returned. The following examples show how the result is mapped to your DTOs.

```
List<Account> result = client.forSql("SELECT * FROM accounts")
    .execute()
    .mapToList(Account.class);

Account result = client.forSql("SELECT * FROM accounts WHERE account_id = 1")
    .execute()
    .mapToSingle(Account.class);
```

In many cases, the database result set contains only a single value. In order to simplify retrieving such results, the client library offers the following API:

```
int numberOfAccounts = client.forSql("SELECT COUNT(*) FROM accounts")
    .execute()
    .singleValue(Integer.class);
```

Troubleshooting Data API issues

Use the following sections, titled with common error messages, to help troubleshoot problems that you have with the Data API.

Topics

- [Transaction <transaction_ID> is not found \(p. 201\)](#)
- [Packet for query is too large \(p. 201\)](#)
- [Database response exceeded size limit \(p. 201\)](#)
- [HttpEndpoint is not enabled for cluster <cluster_ID> \(p. 202\)](#)

Transaction <transaction_ID> is not found

In this case, the transaction ID specified in a Data API call wasn't found. The cause for this issue is almost always one of the following:

- The specified transaction ID wasn't created by a [BeginTransaction](#) call.
- The specified transaction ID has expired.

A transaction expires if no call uses the transaction ID within three minutes.

To solve the issue, make sure that your call has a valid transaction ID. Also make sure that each transaction call runs within three minutes of the last one.

For information about running transactions, see [Calling the Data API \(p. 186\)](#).

Packet for query is too large

In this case, the result set returned for a row was too large. The Data API size limit is 64 KB per row in the result set returned by the database.

To solve this issue, make sure that each row in a result set is 64 KB or less.

Database response exceeded size limit

In this case, the size of the result set returned by the database was too large. The Data API limit is 1 MiB in the result set returned by the database.

To solve this issue, make sure that calls to the Data API return 1 MiB of data or less. If you need to return more than 1 MiB, you can use multiple [ExecuteStatement](#) calls with the `LIMIT` clause in your query.

For more information about the `LIMIT` clause, see [SELECT syntax](#) in the MySQL documentation.

HttpEndpoint is not enabled for cluster <cluster_ID>

The cause for this issue is almost always one of the following:

- The Data API isn't enabled for the Aurora Serverless DB cluster. To use the Data API with an Aurora Serverless DB cluster, the Data API must be enabled for the DB cluster.
- The DB cluster was renamed after the Data API was enabled for it.

If the Data API has not been enabled for the DB cluster, enable it.

If the DB cluster was renamed after the Data API was enabled for the DB cluster, disable the Data API and then enable it again.

For information about enabling the Data API, see [Enabling the Data API \(p. 182\)](#).

Logging Data API calls with AWS CloudTrail

Data API is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Data API. CloudTrail captures all API calls for Data API as events, including calls from the Amazon RDS console and from code calls to the Data API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Data API. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the data collected by CloudTrail, you can determine a lot of information. This information includes the request that was made to Data API, the IP address the request was made from, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#).

Working with Data API information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Data API, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing events with CloudTrail event history](#) in the [AWS CloudTrail User Guide](#).

For an ongoing record of events in your AWS account, including events for Data API, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in the [AWS CloudTrail User Guide](#):

- [Overview for creating a trail](#)
- [CloudTrail supported services and integrations](#)
- [Configuring Amazon SNS notifications for CloudTrail](#)
- [Receiving CloudTrail log files from multiple Regions](#) and [Receiving CloudTrail log files from multiple accounts](#)

All Data API operations are logged by CloudTrail and documented in the [Amazon RDS data service API reference](#). For example, calls to the `BatchExecuteStatement`, `BeginTransaction`, `CommitTransaction`, and `ExecuteStatement` operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity element](#).

Understanding Data API log file entries

A *trail* is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An *event* represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `ExecuteStatement` operation.

```
{  
    "eventVersion": "1.05",  
    "userIdentity": {  
        "type": "IAMUser",  
        "principalId": "AKIAIOSFODNN7EXAMPLE",  
        "arn": "arn:aws:iam::123456789012:user/johndoe",  
        "accountId": "123456789012",  
        "accessKeyId": "AKIAI44QH8DHBEEXAMPLE",  
        "userName": "johndoe"  
    },  
    "eventTime": "2019-12-18T00:49:34Z",  
    "eventSource": "rdsdata.amazonaws.com",  
    "eventName": "ExecuteStatement",  
    "awsRegion": "us-east-1",  
    "sourceIPAddress": "192.0.2.0",  
    "userAgent": "aws-cli/1.16.102 Python/3.7.2 Windows/10 botocore/1.12.92",  
    "requestParameters": {  
        "continueAfterTimeout": false,  
        "database": "*****",  
        "includeResultMetadata": false,  
        "parameters": [],  
        "resourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:my-database-1",  
        "schema": "*****",  
        "secretArn": "arn:aws:secretsmanager:us-east-1:123456789012:secret:dataapisecret-  
ABC123",  
        "sql": "*****"  
    },  
    "responseElements": null,  
    "requestID": "6ba9a36e-b3aa-4ca8-9a2e-15a9eada988e",  
    "eventID": "a2c7a357-ee8e-4755-a0d0-aed11ed4253a",  
    "eventType": "AwsApiCall",  
    "recipientAccountId": "123456789012"  
}
```

Excluding Data API events from an AWS CloudTrail trail

Most Data API users rely on the events in an AWS CloudTrail trail to provide a record of Data API operations. The trail can be a valuable source of data for auditing critical events, such as a SQL

statement that deleted rows in a table. In some cases, the metadata in a CloudTrail log entry can help you to avoid or resolve errors.

However, because the Data API can generate a large number of events, you can exclude Data API events from a CloudTrail trail. This per-trail setting excludes all Data API events. You can't exclude particular Data API events.

To exclude Data API events from a trail, do the following:

- In the CloudTrail console, choose the **Exclude Amazon RDS Data API events** setting when you [create a trail](#) or [update a trail](#).
- In the CloudTrail API, use the [PutEventSelectors](#) operation. Add the `ExcludeManagementEventSources` attribute to your event selectors with a value of `rdsdata.amazonaws.com`. For more information, see [Creating, updating, and managing trails with the AWS Command Line Interface](#) in the *AWS CloudTrail User Guide*.

Warning

Excluding Data API events from a CloudTrail log can obscure Data API actions. Be cautious when giving principals the `cloudtrail:PutEventSelectors` permission that is required to perform this operation.

You can turn off this exclusion at any time by changing the console setting or the event selectors for a trail. The trail will then start recording Data API events. However, it can't recover Data API events that occurred while the exclusion was effective.

When you exclude Data API events by using the console or API, the resulting CloudTrail `PutEventSelectors` API operation is also logged in your CloudTrail logs. If Data API events don't appear in your CloudTrail logs, look for a `PutEventSelectors` event with the `ExcludeManagementEventSources` attribute set to `rdsdata.amazonaws.com`.

For more information, see [Logging management events for trails](#) in the *AWS CloudTrail User Guide*.

Using the query editor for Aurora Serverless

With the query editor for Aurora Serverless, you can run SQL queries in the RDS console. You can run any valid SQL statement on the Aurora Serverless DB cluster, including data manipulation and data definition statements.

The query editor requires an Aurora Serverless DB cluster with the Data API enabled. For information about creating an Aurora Serverless DB cluster with the Data API enabled, see [Using the Data API for Aurora Serverless \(p. 178\)](#).

Availability of the query editor

The query editor is only available for the following Aurora Serverless DB clusters:

- Aurora with MySQL version 5.6 compatibility
- Aurora with MySQL version 5.7 compatibility
- Aurora with PostgreSQL version 10.7 compatibility

The query editor is currently available for Aurora Serverless in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)

- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)

Authorizing access to the query editor

A user must be authorized to run queries in the query editor. You can authorize a user to run queries in the query editor by adding the `AmazonRDSDataFullAccess` policy, a predefined AWS Identity and Access Management (IAM) policy, to that user.

You can also create an IAM policy that grants access to the query editor. After you create the policy, add it to each user that requires access to the query editor.

The following policy provides the minimum required permissions for a user to access the query editor.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "QueryEditor0",  
            "Effect": "Allow",  
            "Action": [  
                "secretsmanager:GetSecretValue",  
                "secretsmanager:PutResourcePolicy",  
                "secretsmanager:PutSecretValue",  
                "secretsmanager>DeleteSecret",  
                "secretsmanager:DescribeSecret",  
                "secretsmanager:TagResource"  
            ],  
            "Resource": "arn:aws:secretsmanager:*:secret:rds-db-credentials/*"  
        },  
        {  
            "Sid": "QueryEditor1",  
            "Effect": "Allow",  
            "Action": [  
                "secretsmanager:GetRandomPassword",  
                "tag:GetResources",  
                "secretsmanager>CreateSecret",  
                "secretsmanager>ListSecrets",  
                "dbqms>CreateFavoriteQuery",  
                "dbqms:DescribeFavoriteQueries",  
                "dbqms:UpdateFavoriteQuery",  
                "dbqms>DeleteFavoriteQueries",  
                "dbqms:GetQueryString",  
                "dbqms>CreateQueryHistory",  
                "dbqms:UpdateQueryHistory",  
                "dbqms:DeleteQueryHistory"  
            ]  
        }  
    ]  
}
```

```
        "dbqms>DeleteQueryHistory",
        "dbqms>DescribeQueryHistory",
        "rds-data:BatchExecuteStatement",
        "rds-data:BeginTransaction",
        "rds-data:CommitTransaction",
        "rds-data:ExecuteStatement",
        "rds-data:RollbackTransaction"
    ],
    "Resource": "*"
}
]
```

For information about creating an IAM policy, see [Creating IAM policies](#) in the *AWS Identity and Access Management User Guide*.

For information about adding an IAM policy to a user, see [Adding and removing IAM identity permissions](#) in the *AWS Identity and Access Management User Guide*.

Running queries in the query editor

You can run SQL statements on an Aurora Serverless DB cluster in the query editor.

To run a query in the query editor

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the Aurora Serverless DB clusters that you want to query.
3. In the navigation pane, choose **Databases**.
4. Choose the Aurora Serverless DB cluster that you want to run SQL queries against.
5. For **Actions**, choose **Query**. If you haven't connected to the database before, the **Connect to database** page opens.

Connect to database

You need to choose a database and enter the database credentials to use the query editor. We will be storing your credentials and the connection in the AWS Secrets Manager service. [Learn more](#)

Database instance or cluster

database-1

Database username

Add new database credentials

Enter database username

Enter database password

Enter the name of the database or schema (optional)

Enter the name for schemas collection

Enter database or schema name

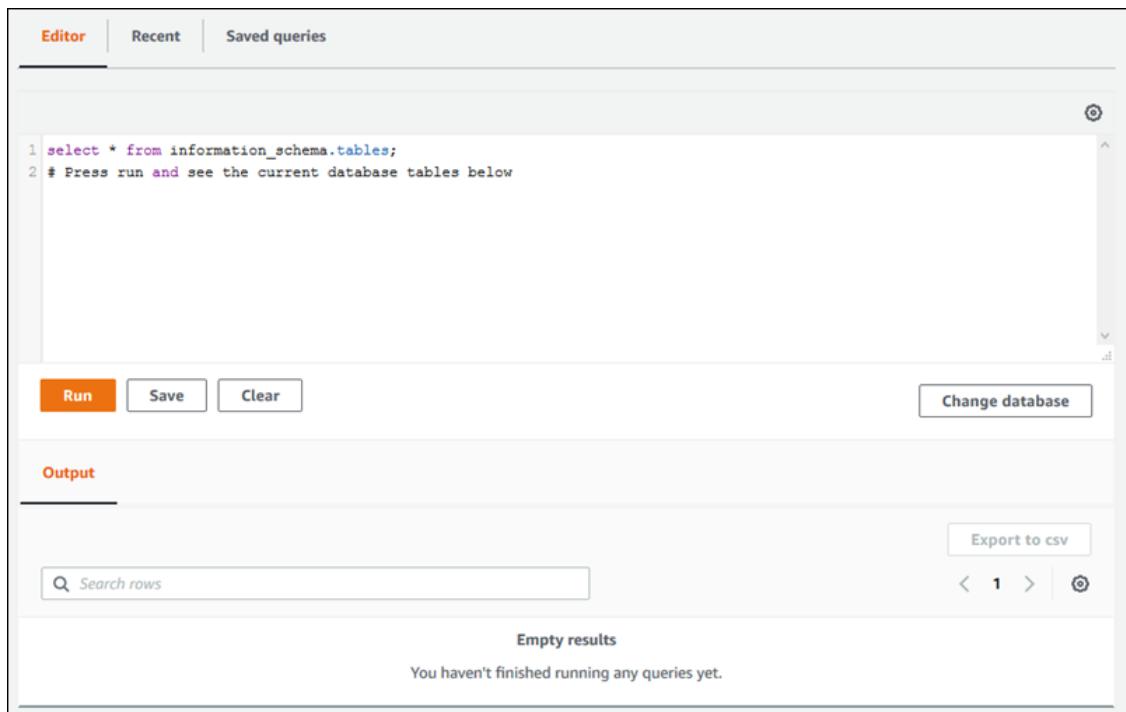

Cancel **Connect to database**

6. Enter the following information:
 - a. For **Database instance or cluster**, choose the Aurora Serverless DB cluster that you want to run SQL queries on.
 - b. For **Database username**, choose the user name of the database user to connect with, or choose **Add new database credentials**. If you choose **Add new database credentials**, enter the user name for the new database credentials in **Enter database username**.
 - c. For **Enter database password**, enter the password for the database user that you chose.
 - d. In the last box, enter the name of the database or schema that you want to use for the Aurora DB cluster.
 - e. Choose **Connect to database**.

Note

If your connection is successful, your connection and authentication information are stored in AWS Secrets Manager. You don't need to enter the connection information again.

7. In the query editor, enter the SQL query that you want to run on the database.

A screenshot of the Amazon Aurora Query Editor interface. At the top, there are three tabs: 'Editor' (which is selected), 'Recent', and 'Saved queries'. Below the tabs, a code editor contains the following SQL script:

```
1 select * from information_schema.tables;
2 # Press run and see the current database tables below
```

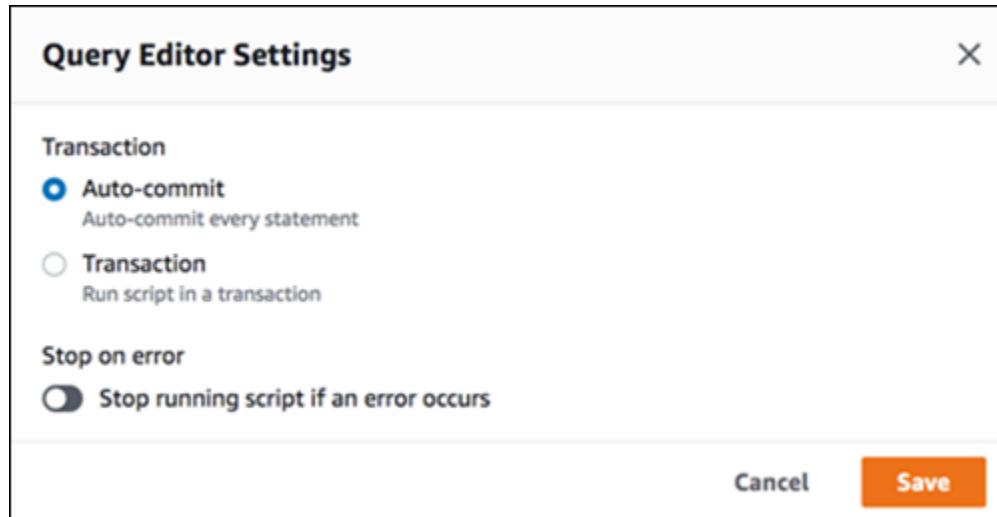

Below the code editor are four buttons: 'Run' (orange), 'Save', 'Clear', and 'Change database'. The 'Output' tab is selected, showing a search bar ('Search rows') and a message: 'Empty results' and 'You haven't finished running any queries yet.' There is also a 'Change database' button and an 'Export to csv' link.

Each SQL statement can commit automatically, or you can run SQL statements in a script as part of a transaction. To control this behavior, choose the gear icon above the query window.

A screenshot of the Amazon Aurora Query Editor interface, similar to the one above but with a red circle highlighting the gear icon located at the top right of the main window area.

The **Query Editor Settings** window appears.

If you choose **Auto-commit**, every SQL statement commits automatically. If you choose **Transaction**, you can run a group of statements in a script. Statements are automatically committed at the end of the script unless explicitly committed or rolled back before then. Also, you can choose to stop a running script if an error occurs by enabling **Stop on error**.

Note

In a group of statements, data definition language (DDL) statements can cause previous data manipulation language (DML) statements to commit. You can also include COMMIT and ROLLBACK statements in a group of statements in a script.

After you make your choices in the **Query Editor Settings** window, choose **Save**.

8. Choose **Run** or press Ctrl+Enter, and the query editor displays the results of your query.

After running the query, save it to **Saved queries** by choosing **Save**.

Export the query results to spreadsheet format by choosing **Export to csv**.

You can find, edit, and rerun previous queries. To do so, choose the **Recent** tab or the **Saved queries** tab, choose the query text, and then choose **Run**.

To change the database, choose **Change database**.

Database Query Metadata Service (DBQMS) API reference

The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.

The following DBQMS actions are supported:

Topics

- [CreateFavoriteQuery \(p. 210\)](#)
- [CreateQueryHistory \(p. 210\)](#)
- [CreateTab \(p. 210\)](#)
- [DeleteFavoriteQueries \(p. 210\)](#)
- [DeleteQueryHistory \(p. 210\)](#)
- [DeleteTab \(p. 210\)](#)

- [DescribeFavoriteQueries \(p. 210\)](#)
- [DescribeQueryHistory \(p. 210\)](#)
- [DescribeTabs \(p. 210\)](#)
- [GetQueryString \(p. 210\)](#)
- [UpdateFavoriteQuery \(p. 210\)](#)
- [UpdateQueryHistory \(p. 210\)](#)
- [UpdateTab \(p. 211\)](#)

CreateFavoriteQuery

Save a new favorite query. Each IAM user can create up to 1000 saved queries. This limit is subject to change in the future.

CreateQueryHistory

Save a new query history entry.

CreateTab

Save a new query tab. Each IAM user can create up to 10 query tabs.

DeleteFavoriteQueries

Delete one or more saved queries.

DeleteQueryHistory

Delete query history entries.

DeleteTab

Delete query tab entries.

DescribeFavoriteQueries

List saved queries created by an IAM user in a given account.

DescribeQueryHistory

List query history entries.

DescribeTabs

List query tabs created by an IAM user in a given account.

GetQueryString

Retrieve full query text from a query ID.

UpdateFavoriteQuery

Update the query string, description, name, or expiration date.

UpdateQueryHistory

Update the status of query history.

UpdateTab

Update the query tab name and query string.

Using Amazon Aurora Serverless v2 (preview)

Amazon Aurora Serverless v2 with MySQL compatibility is in preview release and is subject to change. Aurora Serverless v2 (preview) is not covered by the Amazon RDS service level agreement (SLA). Don't use Aurora Serverless v2 (preview) for production databases. All resources and data will be deleted when the preview ends.

Continuously monitoring and adjusting capacity for multiple databases so that you stay within budget can be a daunting task. You don't want to pay for more computing resources than you use. But you also can't afford to spend a lot of time reallocating resources to achieve a better price-performance ratio. For unpredictable workloads, multitenant, and distributed database environments that can have wide variances in consumption, this task is especially challenging.

By using Amazon Aurora Serverless v2 (Amazon Aurora Serverless version 2), now in preview, you can get optimal cost performance for your database clusters. Capacity is adjusted automatically based on application demand, and you're charged only for the resources that your DB clusters consume.

Topics

- [Limitations of Aurora Serverless v2 \(preview\) \(p. 215\)](#)
- [Creating an Aurora Serverless v2 \(preview\) DB cluster \(p. 216\)](#)
- [Creating a snapshot of an Aurora Serverless v2 \(preview\) DB cluster \(p. 219\)](#)
- [Modifying an Aurora Serverless v2 \(preview\) DB cluster \(p. 220\)](#)
- [Deleting an Aurora Serverless v2 \(preview\) DB cluster \(p. 222\)](#)
- [Restoring an Aurora Serverless v2 \(preview\) DB cluster to a point in time \(p. 223\)](#)

How Aurora Serverless v2 (preview) works

Amazon Aurora Serverless v2 with MySQL compatibility is in preview release and is subject to change. Aurora Serverless v2 (preview) is not covered by the Amazon RDS service level agreement (SLA). Don't use Aurora Serverless v2 (preview) for production databases. All resources and data will be deleted when the preview ends.

Amazon Aurora Serverless v2 (preview) has been architected from the ground up to support serverless DB clusters that are instantly scalable. The Aurora Serverless v2 (preview) architecture rests on a lightweight foundation that's engineered to provide the security and isolation needed in multitenant serverless cloud environments. This foundation has very little overhead so it can respond quickly. It's also powerful enough to meet dramatic increases in processing demand.

Instant autoscaling

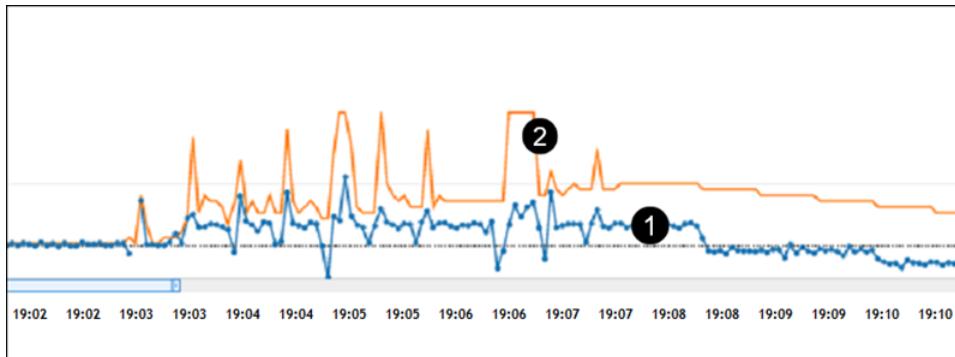

When you create your Aurora Serverless v2 (preview) DB cluster, you define its capacity as a range between minimum and maximum number of Aurora capacity units (ACUs):

- Minimum Aurora capacity units – The smallest number of ACUs down to which your Aurora Serverless v2 (preview) DB cluster can scale.
- Maximum Aurora capacity units – The largest number of ACUs up to which your Aurora Serverless v2 (preview) DB cluster can scale.

Each ACU provides 2 GiB (gibibytes) of memory (RAM) and associated virtual processor (vCPU) with networking.

Unlike Aurora Serverless v1, which scales by doubling ACUs each time the DB cluster reaches a threshold, Aurora Serverless v2 (preview) can increase ACUs incrementally. When your workload demand begins to reach the current resource capacity, your Aurora Serverless v2 (preview) DB cluster scales the number of ACUs. Your cluster scales ACUs in the increments required to provide the best performance for the resources consumed.

The following screenshot shows instant autoscaling in action. It's an extract from Amazon CloudWatch comparing processing load to the number of ACUs consumed by an Aurora Serverless v2 (preview) DB cluster over time for a simulated "flash sale" scenario. The simulation models an order system that processes about 10 orders per second (using 4 ACUs) during regular operations. A load testing tool generates various increases in orders mimicking a "flash sale," until the system is processing 275 orders per second (and 22 ACUs) at its peak.

In the screenshot, these numbers indicate this information:

1. Orders processed each second – Processing load as customers respond to a "flash sale" for a product. The line shows the number of orders being processed each second. Order processing involves multiple database actions. These include checking inventory, processing the new order, creating a shipment order, adjusting the inventory amount, and initiating shipping by notifying the warehouse system.
2. Aurora capacity units (ACUs) – Memory and CPU applied over time to increasing and decreasing demand. The line shows the surge of ACUs applied to the workload (line 1) when orders reach their highest point, about 275 per second.

An ACU is made up of both memory (RAM) and processor (CPU). Increases in CPU utilization respond immediately to workload demands. When the demand starts to decline from its peak, the scale down from the maximum ACU occurs more slowly, as memory is more gradually released (than CPU). This is a deliberate architectural choice. Aurora Serverless v2 (preview) releases memory more gradually as demand lessens to avoid affecting the workload.

Logging with Amazon CloudWatch

As with all Aurora DB clusters, error logs for Aurora Serverless v2 (preview) are enabled by default. However, unlike with provisioned Aurora DB clusters, you can't view the logs for Aurora Serverless v2 (preview) in the Amazon RDS console. Aurora Serverless v2 (preview) automatically uploads the error logs to Amazon CloudWatch.

Aurora Serverless v2 (preview) also uploads your Aurora MySQL log data to CloudWatch for the types of logs that you specify. You choose the logs for uploading by changing values for several log-related DB cluster parameters for your Aurora Serverless v2 (preview) DB cluster. As with any type of Aurora DB cluster, you can't modify the default DB cluster parameter group. Instead, create your own DB cluster parameter group based on a default parameter for your DB cluster and engine type. For Aurora Serverless v2 (preview) and Aurora Serverless v1, you use a DB cluster parameter group only.

We recommend that you create your custom DB cluster parameter group before creating your Aurora Serverless v2 (preview) DB cluster, so that it's available to choose when you create a database on the console.

You can also modify your Aurora Serverless v2 (preview) DB cluster later to use your custom DB cluster parameter group. For more information, see [Modifying your DB cluster to use a custom DB cluster parameter group \(p. 221\)](#).

For Aurora MySQL logging, you can activate the following parameters:

- `general_log` – Set to 1 to turn on the general log (default is off, or 0).
- `slow_query_log` – Set to 1 to turn on the slow query log. (default is off, or 0).
- `server_audit_logging` – Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the `server_audit_events` parameter.
- `server_audit_events` – The list of events to capture in the logs.

For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster \(p. 914\)](#).

After you apply your modified DB cluster parameter group to your Aurora Serverless v2 (preview) DB cluster, you can view the logs in CloudWatch.

To view logs for your Aurora Serverless v2 (preview) DB cluster

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose **US East (N. Virginia)** for the Region.
3. Choose **Log groups**.
4. Choose your Aurora Serverless v2 (preview) DB cluster log from the list. For error logs, the naming pattern is as follows.

```
/aws/rds/cluster/cluster-name/error
```

For more information on viewing details on your logs, see [Monitoring log events in Amazon CloudWatch \(p. 1020\)](#).

Monitoring capacity with Amazon CloudWatch

Aurora Serverless v2 (preview) introduces a new metric for monitoring Aurora DB cluster capacity, `ServerlessDatabaseCapacity`. You can use CloudWatch to view your DB cluster's capacity as it scales up and down. You can also compare `ServerlessDatabaseCapacity` to other metrics to see how changes in workloads affect resource consumption.

To monitor your Aurora Serverless v2 (preview) DB cluster's capacity

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose the US East (N. Virginia) Region.
3. Choose **Metrics**. All available metrics appear as cards in the console, grouped by service name.
4. Choose **RDS**.

You can also use the **Search** box to find `ServerlessDatabaseCapacity`.

We recommend that you set up a CloudWatch dashboard to monitor your Aurora Serverless v2 (preview) DB cluster capacity using this new metric. To learn how, see [Building dashboards with CloudWatch](#). You

can compare `ServerlessDatabaseCapacity` to `DatabaseUsedMemory`, `DatabaseConnections`, and `DMLThroughput` to assess how your DB cluster is responding during operations.

To learn more about using Amazon CloudWatch with Amazon Aurora, see [Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs \(p. 1017\)](#).

Limitations of Aurora Serverless v2 (preview)

Amazon Aurora Serverless v2 with MySQL compatibility is in preview release and is subject to change. Aurora Serverless v2 (preview) is not covered by the Amazon RDS service level agreement (SLA). Don't use Aurora Serverless v2 (preview) for production databases. All resources and data will be deleted when the preview ends.

The following limitations apply to Amazon Aurora Serverless v2 (preview):

- You can work with Amazon Aurora Serverless v2 (preview) in the preview environment only. You are limited to working with Aurora Serverless v2 (preview) in this environment. To use any of your other existing AWS services, such as Amazon EC2 and Amazon CloudWatch, access them through the AWS Management Console in the US East (N. Virginia) Region.
- You can work with Amazon Aurora Serverless v2 (preview) using the console only. AWS CLI commands and Amazon RDS API operations for creating and working Aurora Serverless v2 (preview) DB clusters aren't currently available.
- You can create only Aurora MySQL 5.7 (2.07) DB clusters using Aurora Serverless v2 (preview). Aurora PostgreSQL isn't currently available for Aurora Serverless v2 (preview).
- Aurora Serverless v2 (preview) clusters can be created in the Availability Zones with these zoneids only:
 - use1-az2
 - use1-az4
 - use1-az6
- Your Aurora Serverless v2 (preview) DB clusters have a default capacity that ranges from a minimum of 4 Aurora capacity units (ACUs) to 32 ACUs. Each ACU provides the equivalent of approximately 2 gibabytes (GiB) of RAM and associated CPU and networking.
- You can't give an Aurora Serverless v2 (preview) DB cluster a public IP address.
- You must create your Aurora Serverless v2 (preview) DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. You can access your Aurora Serverless v2 (preview) DB cluster only from within a VPC based on Amazon VPC.
- Aurora Serverless v2 (preview) databases are accessible only through port 3306. Aurora Serverless v2 (preview) assigns port 3306 to any Aurora MySQL DB instances that you create. You can't change the port number.
- Aurora Serverless v2 (preview) doesn't support the following Aurora features:
 - Amazon RDS Performance Insights
 - Amazon RDS Proxy
 - Aurora backtracking
 - Aurora cloning
 - Aurora global databases
 - Aurora multi-master clusters
 - Aurora Replicas
 - AWS Identity and Access Management (IAM) database authentication
 - Data API for Aurora Serverless v1
 - Exporting snapshots created from Aurora Serverless v2 (preview) DB clusters to Amazon S3 buckets

- Importing data from Amazon S3 into Aurora Serverless v2 (preview) DB cluster tables
- Invoking AWS Lambda functions from within your Aurora Serverless v2 (preview) database
- Query editor for Aurora Serverless v1
- Restoring snapshots from Aurora provisioned DB clusters

Creating an Aurora Serverless v2 (preview) DB cluster

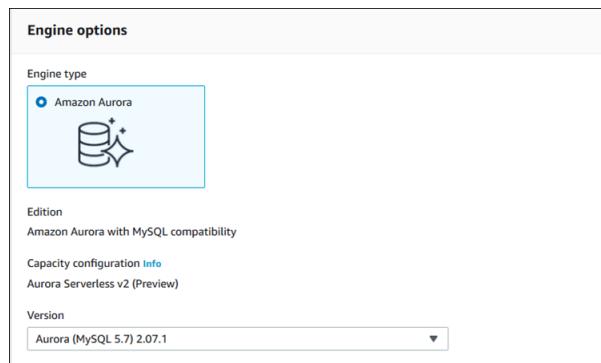

Amazon Aurora Serverless v2 with MySQL compatibility is in preview release and is subject to change. Aurora Serverless v2 (preview) is not covered by the Amazon RDS service level agreement (SLA). Don't use Aurora Serverless v2 (preview) for production databases. All resources and data will be deleted when the preview ends.

To work with Amazon Aurora Serverless v2 (preview), you must apply for access. For more information, see the [Aurora Serverless v2 \(preview\)](#) page.

After you're approved for access, you can sign in to the preview using the console. Currently, you can create an Amazon Aurora Serverless v2 (preview) DB cluster with the console only.

To create an Aurora Serverless v2 (preview) DB cluster

1. Sign in to the preview using the AWS Management Console and open the Amazon RDS console.
2. Choose **Create Database**. For this preview, you see the available choices preselected for **Engine options**:
 - Amazon Aurora for **Engine type**
 - Amazon Aurora with MySQL compatibility for **Edition**
 - Aurora Serverless v2 (preview) for **Capacity configuration**
 - Aurora (MySQL 5.7) 2.07.1 for **Version**

3. For **Settings**, do the following:
 - a. Accept the default DB cluster identifier or choose your own.
 - b. Enter your own password for the default `admin` account for the DB cluster, or have Aurora Serverless v2 (preview) generate one for you. If you choose **Auto generate a password**, you get an option to copy the password.

DB cluster identifier [Info](#)
Type a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Credentials Settings

Master username [Info](#)
Type a login ID for the master user of your DB instance.

1 to 16 alphanumeric characters. First character must be a letter
 Auto generate a password
Amazon RDS can generate a password for you, or you can specify your own password

Master password [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote)', "(double quote)" and @ (at sign).
Confirm password [Info](#)

- For **Capacity settings**, you can accept the default range (4 ACUs minimum to 32 ACUs maximum). Or you can choose other values for minimum and maximum capacity units.

For more information about Aurora Serverless v2 (preview) capacity units, see [Instant autoscaling \(p. 212\)](#).

Capacity settings [Info](#)
Specify the minimum and maximum values for the capacity range. Database capacity is measured in Aurora capacity units (ACUs). 1 ACU has approximately 2 GB of memory with corresponding CPU and networking, similar to what is used in Aurora user-provisioned instances.

Minimum Aurora capacity unit 8 GiB	Maximum Aurora capacity unit 64 GiB
<input type="text" value="4"/> ACUs	<input type="text" value="32"/> ACUs

- For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.

To use your own VPC, we recommend that you create it along with related subnets, subnet group, and security group in advance. If you do this, these are available for you to choose when you're creating your Aurora Serverless v2 (preview) DB cluster.

To learn how, see [How to create a VPC for use with Amazon Aurora](#).

Connectivity

Virtual private cloud (VPC) [Info](#)
VPC that defines the virtual networking environment for this DB cluster.

Only VPCs with a corresponding DB subnet group are listed.

After a database is created, you can't change the VPC selection.

Additional connectivity configuration

Subnet group [Info](#)
DB subnet group that defines which subnets and IP ranges the DB instance can use in the VPC you selected.

VPC security group
Choose one or more RDS security groups to allow access to your database. Ensure that the security group rules allow incoming traffic from EC2 instances and devices outside your VPC. (Security groups are required for publicly accessible databases.)

Choose existing
Choose existing VPC security groups

Create new
Create new VPC security group

Existing VPC security groups

6. For **Additional configuration**, enter a name for **Initial database name** to create a database for your Aurora Serverless v2 (preview) cluster.

If you created a custom DB cluster parameter group, choose it for **DB cluster parameter group**. If you want to view your Aurora MySQL logs in Amazon CloudWatch, make sure to use a custom DB cluster parameter group. For more information, see [Logging with Amazon CloudWatch \(p. 213\)](#).

Additional configuration
Database options, encryption enabled, backup enabled, backtrack disabled, delete protection enabled

Database options

Initial database name [Info](#)
 If you do not specify a database name, Amazon RDS does not create a database.

DB cluster parameter group [Info](#)

Backup
Creates a point-in-time snapshot of your database

Backup retention period [Info](#)
Choose the number of days that RDS should retain automatic backups for this instance.

Copy tags to snapshots

Encryption

Master key [Info](#)

Account

KMS key ID

Deletion protection

Enable deletion protection
Protects the database from being deleted accidentally. While this option is enabled, you can't delete the database.

The Aurora Serverless v2 (preview) cluster volume is always encrypted. You can't disable encryption, but you can choose your own encryption key. For more information, see [Encrypting Amazon Aurora resources](#).

7. Acknowledge the limited service agreement.

Aurora Serverless v2 is now available in preview
Aurora Serverless v2 is not covered by the Amazon RDS service level agreement (SLA), published at <https://aws.amazon.com/rds/sla/>.

I acknowledge this limited service agreement for Aurora Serverless v2 and I will not configure Aurora Serverless v2 for production databases.

You are responsible for ensuring that you have all of the necessary rights for any third-party products or services that you use with AWS services.

Create database

8. Choose **Create database** to create your Aurora Serverless v2 (preview) DB cluster.

You can connect to your Aurora Serverless v2 (preview) DB cluster by using its endpoint. The endpoint is listed on the **Connectivity & security** tab of the console, under **Endpoint & Port**. For more information about how to connect to Aurora DB clusters, see [Connecting to an Amazon Aurora DB cluster \(p. 281\)](#).

Aurora Serverless v2 (preview) creates your DB instance using port 3306. Make sure to configure the security group for your Aurora Serverless v2 (preview) DB cluster to allow access to the MySQL/Aurora port (3306).

However, you can't access the Amazon VPC configurations directly from the preview console.

To modify your security group settings

1. Sign in to your <https://console.aws.amazon.com/vpc/>.
2. Choose the US East (N. Virginia) Region.

3. For **Security Group**, choose the security group associated with your Aurora Serverless v2 (preview) DB cluster.
4. Edit values for **Inbound rules** and **Outbound rules** as needed.

To learn more about configuring your VPC for Aurora, see [Amazon Virtual Private Cloud VPCs and Amazon Aurora](#).

Creating a snapshot of an Aurora Serverless v2 (preview) DB cluster

Amazon Aurora Serverless v2 with MySQL compatibility is in preview release and is subject to change. Aurora Serverless v2 (preview) is not covered by the Amazon RDS service level agreement (SLA). Don't use Aurora Serverless v2 (preview) for production databases. All resources and data will be deleted when the preview ends.

Amazon Aurora Serverless v2 (preview) routinely creates snapshots of your DB cluster as backups. Unlike automated backups, manual snapshots aren't subject to the backup retention period. Snapshots don't expire. For more information about snapshots in general, see [Creating a DB cluster snapshot \(p. 495\)](#).

Currently, you can create an Aurora Serverless v2 (preview) DB cluster snapshot using the console only.

To create a DB cluster snapshot

1. Sign in to the preview using the AWS Management Console and open the Amazon RDS console.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora Serverless v2 (preview) DB cluster use for your snapshot.
4. Choose **Actions**, and then choose **Take snapshot**.

The **Take DB Snapshot** window appears.

5. For **Snapshot name**, enter the name of your Aurora Serverless v2 (preview) DB cluster.

Take DB Snapshot

Settings
To take a snapshot of this DB instance you must provide a name for the snapshot.

DB instance
The unique key that identifies a DB instance. This parameter isn't case-sensitive.
cluster5

Snapshot name
The Identifier for the DB Snapshot.

Cancel **Take Snapshot**

6. Choose **Take Snapshot**.

Modifying an Aurora Serverless v2 (preview) DB cluster

Amazon Aurora Serverless v2 with MySQL compatibility is in preview release and is subject to change. Aurora Serverless v2 (preview) is not covered by the Amazon RDS service level agreement (SLA). Don't use Aurora Serverless v2 (preview) for production databases. All resources and data will be deleted when the preview ends.

You can change configuration settings for your Aurora Serverless v2 (preview) DB cluster at any time, such as to do the following:

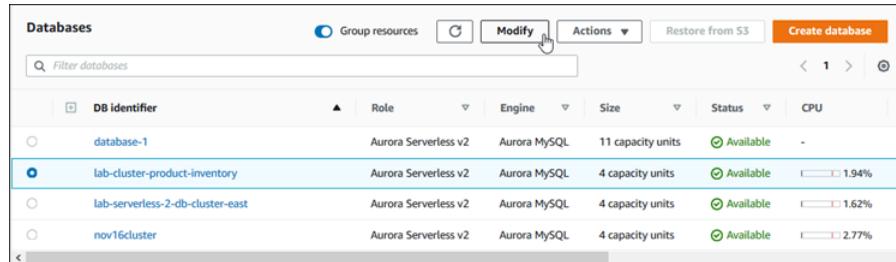

- Change your Aurora Serverless v2 (preview) DB cluster name.
- Turn on (or off) deletion protection for your Aurora Serverless v2 (preview) DB cluster.
- Modify your Aurora Serverless v2 (preview) DB cluster's capacity settings.
- Modify **Additional configuration** settings, such as choosing a custom DB cluster parameter group.

The only configuration option that you can't change for Aurora Serverless v2 (preview) DB cluster is its virtual private cloud (VPC) that you chose when you created it.

Use the following procedure to modify your Aurora Serverless v2 (preview) DB cluster's configuration by using the console.

To modify the configuration of your Aurora Serverless v2 (preview) DB cluster

1. Sign in to the preview using the AWS Management Console and open the Amazon RDS console.
2. In the navigation pane, choose **DB clusters**.
3. Choose your Aurora Serverless v2 (preview) DB cluster from the list.

DB identifier	Role	Engine	Size	Status	CPU
database-1	Aurora Serverless v2	Aurora MySQL	11 capacity units	Available	-
lab-cluster-product-inventory	Aurora Serverless v2	Aurora MySQL	4 capacity units	Available	1.94%
lab-serverless-2-db-cluster-east	Aurora Serverless v2	Aurora MySQL	4 capacity units	Available	1.62%
nov16cluster	Aurora Serverless v2	Aurora MySQL	4 capacity units	Available	2.77%

The configuration settings for your Aurora Serverless v2 (preview) DB cluster appear. Now you can change your cluster's name, password, credentials, and other settings.

Modifying Aurora Serverless v2 (preview) DB cluster capacity

Currently, you can modify the capacity of your Aurora Serverless v2 (preview) DB clusters with the console only.

To modify the capacity of your Aurora Serverless v2 (preview) DB cluster

1. Sign in to the preview using the AWS Management Console and open the Amazon RDS console.
2. In the navigation pane, choose **DB Clusters**.

3. Choose your Aurora Serverless v2 (preview) DB cluster from the list, and then choose **Modify** to open its configuration.

Capacity settings Info
Specify the minimum and maximum values for the capacity range. Database capacity is measured in Aurora capacity units (ACUs). 1 ACU has approximately 2 GiB of memory with corresponding CPU and networking, similar to what is used in Aurora user-provisioned instances.

Minimum Aurora capacity unit 8 GiB 4	ACUs	Maximum Aurora capacity unit 52 GiB 26	ACUs
--	------	--	------

4. For **Capacity settings**, change the minimum number of ACUs or the maximum number of ACUs that you now want for your Aurora Serverless v2 (preview) DB cluster.
5. Choose **Continue**. The **Summary of modifications** appears.

Modify DB cluster: lab-cluster-product-inventory

Summary of modifications
You are about to submit the following modifications. Only values that will change are displayed. Carefully verify your changes and click Modify Cluster.

Attribute	Current value	New value
Maximum Aurora capacity unit	32	26

Cancel Back **Modify cluster**

6. Choose **Modify cluster** to accept the summary of modifications. You can also choose **Back** to modify your changes or **Cancel** to discard your changes.

To learn more about ACUs and scaling for Aurora Serverless v2 (preview), see [Instant autoscaling \(p. 212\)](#).

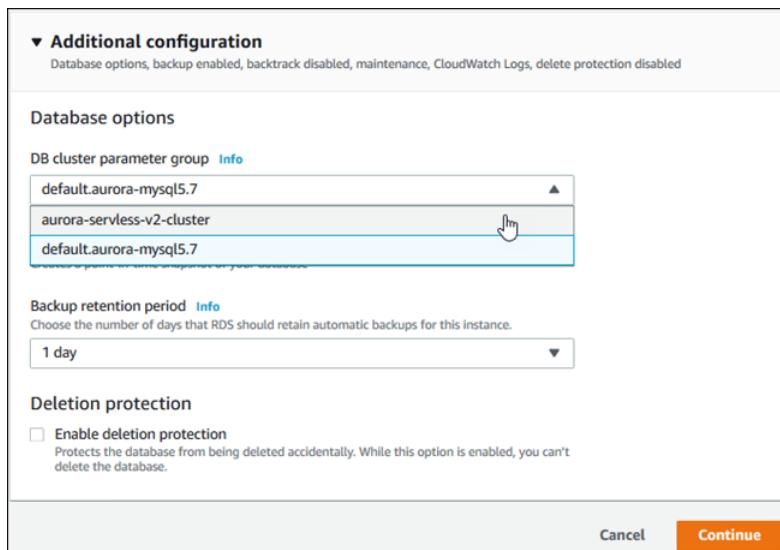

Modifying your DB cluster to use a custom DB cluster parameter group

To use a custom DB cluster parameter group after your Aurora Serverless v2 (preview) is running, modify your existing Aurora Serverless v2 (preview) DB cluster.

Before you can use the following procedure, your custom DB cluster parameter group must exist. To learn how to create a custom DB cluster parameter group, see [Parameter groups and Aurora Serverless v1 \(p. 156\)](#).

To modify your Aurora Serverless v2 (preview) DB cluster to use a custom DB cluster parameter group

1. Sign in to the preview using the AWS Management Console and open the Amazon RDS console.
2. In the navigation pane, choose **DB Clusters**.
3. Choose your Aurora Serverless v2 (preview) DB cluster from the list, and then choose **Modify**.
4. Under **Additional configuration**, choose your custom DB cluster parameter group.

5. Choose **Continue**. The **Summary of modifications** page appears.
6. Choose **Modify cluster** to accept the summary of modifications. Or choose **Back** to modify your changes or **Cancel** to discard your changes.

To learn more about creating custom DB cluster parameter groups, see [Parameter groups and Aurora Serverless v1 \(p. 156\)](#).

Deleting an Aurora Serverless v2 (preview) DB cluster

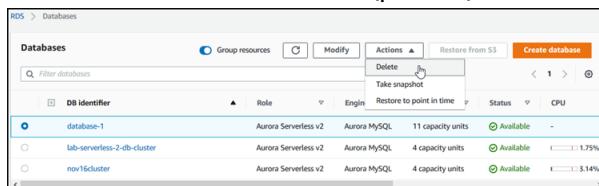

Amazon Aurora Serverless v2 with MySQL compatibility is in preview release and is subject to change. Aurora Serverless v2 (preview) is not covered by the Amazon RDS service level agreement (SLA). Don't use Aurora Serverless v2 (preview) for production databases. All resources and data will be deleted when the preview ends.

When you create your Aurora Serverless v2 (preview) DB clusters, you can choose to disable deletion protection or keep it as is. If the Aurora Serverless v2 (preview) DB cluster that you want to delete was created with deletion protection, make sure to modify your DB cluster to remove deletion protection. Otherwise, you can't delete it. To learn how do this, see [Modifying an Aurora Serverless v2 \(preview\) DB cluster \(p. 220\)](#).

Currently, you can delete an Amazon Aurora Serverless v2 (preview) DB cluster with the console only.

To delete an Aurora Serverless v2 (preview) DB cluster

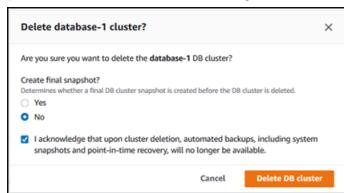

1. Sign in to the preview using the AWS Management Console and open the Amazon RDS console.
2. In the **Resources** section, choose **DB Clusters**.
3. Choose the Aurora Serverless v2 (preview) DB cluster that you want to delete.

4. For **Actions**, choose **Delete**. You're prompted to confirm that you want to delete your Aurora Serverless v2 (preview) DB cluster.
5. We recommend that you keep the preselected options:
 - Yes for **Create final snapshot?**
 - Your Aurora Serverless v2 (preview) DB cluster name plus **-final-snapshot** for **Final snapshot name**. However, you can change the name for your final snapshot in this field.

If you choose **No** for **Create final snapshot?** you can't restore your DB cluster using snapshots or point-in-time recovery.

6. Choose **Delete DB cluster**.

Aurora Serverless v2 (preview) deletes your DB cluster.

Restoring an Aurora Serverless v2 (preview) DB cluster to a point in time

Amazon Aurora Serverless v2 with MySQL compatibility is in preview release and is subject to change. Aurora Serverless v2 (preview) is not covered by the Amazon RDS service level agreement (SLA). Don't use Aurora Serverless v2 (preview) for production databases. All resources and data will be deleted when the preview ends.

You can create a new Aurora Serverless v2 (preview) DB cluster by restoring an existing DB cluster to a specific point in time. You can also use this approach to recover from a failure by recreating your Aurora Serverless v2 (preview) DB cluster from its most recent log files.

To restore your DB cluster to a specific point in time, Aurora creates a new DB cluster. It then applies all transactions from the logs of the existing DB cluster to the new cluster. Depending on the quantity and scope of transactions contained in the logs, this operation might take several hours to complete. For more information about point-in-time recovery, see [Restoring a DB cluster to a specified time \(p. 537\)](#).

Currently, you can restore your Aurora Serverless v2 (preview) DB cluster using the console only.

To restore an Aurora Serverless v2 (preview) DB cluster to a specified point in time

1. Sign in to the preview using the AWS Management Console and open the Amazon RDS console.
2. Choose **Databases**.

3. Choose the Aurora Serverless v2 (preview) DB cluster that you want to restore.
4. For **Actions**, choose **Restore to point in time**. The **Restore DB cluster** page appears.

Restore DB Cluster

You are creating a new DB instance from a source DB instance at a specified time. This new DB instance will have the default DB security group and DB parameter groups.

Restore time

Point in time to restore from

Latest restorable time
West Nov 25 2020 18:42:43 GMT-0800 (Pacific Standard Time)

Custom
Specify a custom date and time to restore from. The date must be before the latest restorable time for the DB instance.

Custom Date Start time
2020/11/22 12 : 00 : 00 UTC

Instance specifications

DB engine
Name of the database engine to be used for this instance.
Aurora MySQL

Source DB cluster
nov16cluster

DB cluster identifier
lab-restored-db-cluster-fiscal-year-end

5. Choose **Latest restorable time**. Or choose **Custom** and specify a date and time that is earlier than the latest restorable time.
6. For **Instance specifications**, keep Aurora MySQL selected for the database engine.
7. For **DB cluster identifier**, enter the name for your newly restored DB cluster.
8. In the **Capacity settings** section, choose the minimum and maximum values that you want for your restored Aurora Serverless v2 (preview) DB cluster.

Capacity settings Info

Specify the minimum and maximum values for the capacity range. Database capacity is measured in Aurora capacity units (ACUs). 1 ACU provides 2 GiB of memory, 1/4th of a vCPU and corresponding networking.

Minimum Aurora capacity unit
8 GiB
4 ACUs

Maximum Aurora capacity unit
44 GiB
22 ACUs

9. In the **Connectivity** section, accept the defaults.
10. For **Additional configuration**, choose the encryption key that you used for the DB cluster you're restoring. Choose the default key unless you used your own key when creating the DB cluster.
11. When you complete the settings on the page, choose **Restore DB Cluster**.

Using Amazon Aurora global databases

Amazon Aurora global databases span multiple AWS Regions, enabling low latency global reads and providing fast recovery from the rare outage that might affect an entire AWS Region. An Aurora global database has a primary DB cluster in one Region, and up to five secondary DB clusters in different Regions.

- [Using Amazon Aurora global databases with other AWS services \(p. 279\)](#)
- [Upgrading an Amazon Aurora global database \(p. 280\)](#)

Overview of Amazon Aurora global databases

By using an Amazon Aurora global database, you can run your globally distributed applications using a single Aurora database that spans multiple AWS Regions.

An Aurora global database consists of one *primary* AWS Region where your data is written, and up to five read-only *secondary* AWS Regions. You issue write operations directly to the primary DB cluster in the primary AWS Region. Aurora replicates data to the secondary AWS Regions using dedicated infrastructure, with latency typically under a second.

In the following diagram, you can find an example Aurora global database that spans two AWS Regions.

You can scale up each secondary cluster independently, by adding one or more Aurora Replicas (read-only Aurora DB instances) to serve read-only workloads.

Only the primary cluster performs write operations. Clients that perform write operations connect to the DB cluster endpoint of the primary DB cluster. As shown in the diagram, Aurora global database uses the cluster storage volume and not the database engine for replication. To learn more, see [Overview of Aurora storage \(p. 64\)](#).

Aurora global databases are designed for applications with a worldwide footprint. The read-only secondary DB clusters (AWS Regions) allow you to support read operations closer to application users. By using features such as write forwarding, you can also configure an Aurora MySQL-based global database so that secondary clusters send data to the primary. For more information, see [Using write forwarding in an Amazon Aurora global database \(p. 255\)](#).

An Aurora global database supports two different approaches to failover. To recover your Aurora global database after an outage in the primary Region, you use the *manual unplanned failover* process. With this process, you fail over your primary to another Region (cross-Region failover). For more information about this process, see [Recovering an Amazon Aurora global database from an unplanned outage \(p. 267\)](#).

For planned operational procedures such as maintenance, you use *managed planned failover*. With this feature, you can relocate the primary cluster of a healthy Aurora global database to one of its secondary Regions with no data loss. To learn more, see [Performing managed planned failovers for Amazon Aurora global databases \(p. 268\)](#).

Advantages of Amazon Aurora global databases

By using Aurora global databases, you can get the following advantages:

- **Global reads with local latency** – If you have offices around the world, you can use an Aurora global database to keep your main sources of information updated in the primary AWS Region. Offices in your other Regions can access the information in their own Region, with local latency.
- **Scalable secondary Aurora DB clusters** – You can scale your secondary clusters by adding more read-only instances (Aurora Replicas) to a secondary AWS Region. The secondary cluster is read-only, so it can support up to 16 read-only Aurora Replica instances rather than the usual limit of 15 for a single Aurora cluster.
- **Fast replication from primary to secondary Aurora DB clusters** – The replication performed by an Aurora global database has little performance impact on the primary DB cluster. The resources of the DB instances are fully devoted to serve application read and write workloads.
- **Recovery from Region-wide outages** – The secondary clusters allow you to make an Aurora global database available in a new primary AWS Region more quickly (lower RTO) and with less data loss (lower RPO) than traditional replication solutions.

Limitations of Amazon Aurora global databases

The following limitations currently apply to Aurora global databases:

- Aurora global databases are available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see [Aurora global databases \(p. 21\)](#).
- Aurora global databases have certain configuration requirements for supported Aurora DB instance classes, maximum number of AWS Regions, and so on. For more information, see [Configuration requirements of an Amazon Aurora global database \(p. 228\)](#).
- Managed planned failover for Aurora global databases requires one of the following Aurora database engines:
 - Aurora MySQL with MySQL 8.0 compatibility, version 3.01.0 and higher
 - Aurora MySQL with MySQL 5.7 compatibility, version 2.09.1 and higher
 - Aurora MySQL with MySQL 5.6 compatibility, version 1.23.1 and higher
 - Aurora PostgreSQL versions 13.3 and higher, 12.4 and higher, 11.9 and higher, and 10.14 and higher
- Aurora global databases currently don't support the following Aurora features:
 - Aurora multi-master clusters

- Aurora Serverless v1
- Backtracking in Aurora
- Amazon RDS Proxy
- Automatic minor version upgrade doesn't apply to Aurora MySQL and Aurora PostgreSQL clusters that are part of an Aurora global database. Note that you can specify this setting for a DB instance that is part of a global database cluster, but the setting has no effect.
- Aurora global databases currently don't support Aurora Auto Scaling for secondary DB clusters.
- You can start database activity streams on Aurora global databases running the following Aurora MySQL and Aurora PostgreSQL versions only.

Database engine	Primary AWS Region	Secondary AWS Regions
Aurora MySQL 5.7	version 2.08 and higher	version 2.08 and higher
Aurora PostgreSQL	version 13.3 and higher	version 13.3 and higher
	version 12.4 and higher	version 12.4 and higher
	version 11.7 and higher	version 11.9 and higher
	version 10.11 and higher	version 10.14 and higher

For information about database activity streams, see [Monitoring Amazon Aurora with Database Activity Streams \(p. 714\)](#).

- With an Aurora global database based on Aurora PostgreSQL, you can't perform a major version upgrade of the Aurora DB engine if the recovery point objective (RPO) feature is turned on. For information about the RPO feature, see [Managing RPOs for Aurora PostgreSQL-based global databases \(p. 272\)](#). For information about upgrading an Aurora global database, see [Upgrading an Amazon Aurora global database \(p. 280\)](#).
- You can't stop or start the Aurora DB clusters in your Aurora global database individually. To learn more, see [Stopping and starting an Amazon Aurora DB cluster \(p. 368\)](#).
- Aurora Replicas attached to the secondary Aurora DB cluster can restart under certain circumstances. If the primary AWS Region's writer DB instance restarts or fails over, Aurora Replicas in secondary Regions also restart. The secondary cluster is then unavailable until all replicas are back in sync with the primary DB cluster's writer instance. This behavior is expected, as documented in [Replication with Amazon Aurora \(p. 70\)](#). Be sure that you understand the impacts to your Aurora global database before making changes to your primary DB cluster. To learn more, see [Recovering an Amazon Aurora global database from an unplanned outage \(p. 267\)](#).
- Aurora PostgreSQL-based DB clusters running in an Aurora global database have the following limitations:
 - Cluster cache management isn't supported for Aurora PostgreSQL DB clusters that are part of Aurora global databases.
 - If the primary DB cluster of your Aurora global database is based on a replica of an Amazon RDS PostgreSQL instance, you can't create a secondary cluster. Don't attempt to create a secondary from that cluster using the AWS Management Console, the AWS CLI, or the `CreateDBCluster` API operation. Attempts to do so time out, and the secondary cluster isn't created.

We recommend that you create secondary DB clusters for your Aurora global databases by using the same version of the Aurora DB engine as the primary. For more information, see [Creating an Amazon Aurora global database \(p. 229\)](#).

Getting started with Amazon Aurora global databases

To get started with Aurora global databases, first decide which Aurora DB engine you want to use and in which AWS Regions. Only specific versions of the Aurora MySQL and Aurora PostgreSQL database engines in certain AWS Regions support Aurora global databases. For the complete list, see [Aurora global databases \(p. 21\)](#).

You can create an Aurora global database in one of the following ways:

- **Create a new Aurora global database with new Aurora DB clusters and Aurora DB instances** – You can do this by following the steps in [Creating an Amazon Aurora global database \(p. 229\)](#). After you create the primary Aurora DB cluster, you then add the secondary AWS Region by following the steps in [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).
- **Use an existing Aurora DB cluster that supports the Aurora global database feature and add an AWS Region to it** – You can do this only if your existing Aurora DB cluster uses a DB engine version that supports the Aurora global mode or is global-compatible. For some DB engine versions, this mode is explicit, but for others, it's not.

Check whether you can choose **Add region** for **Action** on the AWS Management Console when your Aurora DB cluster is selected. If you can, you can use that Aurora DB cluster for your Aurora global cluster. For more information, see [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).

Before creating an Aurora global database, we recommend that you understand all configuration requirements.

Topics

- [Configuration requirements of an Amazon Aurora global database \(p. 228\)](#)
- [Creating an Amazon Aurora global database \(p. 229\)](#)
- [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#)
- [Creating a headless Aurora DB cluster in a secondary Region \(p. 246\)](#)
- [Using a snapshot for your Amazon Aurora global database \(p. 248\)](#)

Configuration requirements of an Amazon Aurora global database

An Aurora global database spans at least two AWS Regions. The primary AWS Region supports an Aurora DB cluster that has one writer Aurora DB instance. A secondary AWS Region runs a read-only Aurora DB cluster made up entirely of Aurora Replicas. At least one secondary AWS Region is required, but an Aurora global database can have up to five secondary AWS Regions. The table lists the maximum Aurora DB clusters, Aurora DB instances, and Aurora Replicas allowed in an Aurora global database.

Description	Primary AWS Region	Secondary AWS Regions
Aurora DB clusters	1	5 (maximum)
Writer instances	1	0
Read-only instances (Aurora replicas), per Aurora DB cluster	15 (max)	16 (total)

Description	Primary AWS Region	Secondary AWS Regions
Read-only instances (max allowed, given actual number of secondary Regions)	15 - s	s = total number of secondary AWS Regions

The Aurora DB clusters that make up an Aurora global database have the following specific requirements:

- **DB instance class requirements** – An Aurora global database requires DB instance classes that are optimized for memory-intensive applications. For information about the memory optimized DB instance classes, see [DB instance classes](#). We recommend that you use a db.r5 or higher instance class.
- **AWS Region requirements** – An Aurora global database needs a primary Aurora DB cluster in one AWS Region, and at least one secondary Aurora DB cluster in a different Region. You can create up to five secondary (read-only) Aurora DB clusters, and each must be in a different Region. In other words, no two Aurora DB clusters in an Aurora global database can be in the same AWS Region.
- **Naming requirements** – The names you choose for each of your Aurora DB clusters must be unique, across all AWS Regions. You can't use the same name for different Aurora DB clusters even though they're in different Regions.

Before you can follow the procedures in this section, you need an AWS account. Complete the setup tasks for working with Amazon Aurora. For more information, see [Setting up your environment for Amazon Aurora \(p. 84\)](#). You also need to complete other preliminary steps for creating any Aurora DB cluster. To learn more, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

Creating an Amazon Aurora global database

In some cases, you might have an existing Aurora provisioned DB cluster running an Aurora database engine that's global-compatible. If so, you can add another AWS Region to it to create your Aurora global database. To do so, see [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).

To create an Aurora global database by using the AWS Management Console, the AWS CLI, or the RDS API, use the following steps.

Console

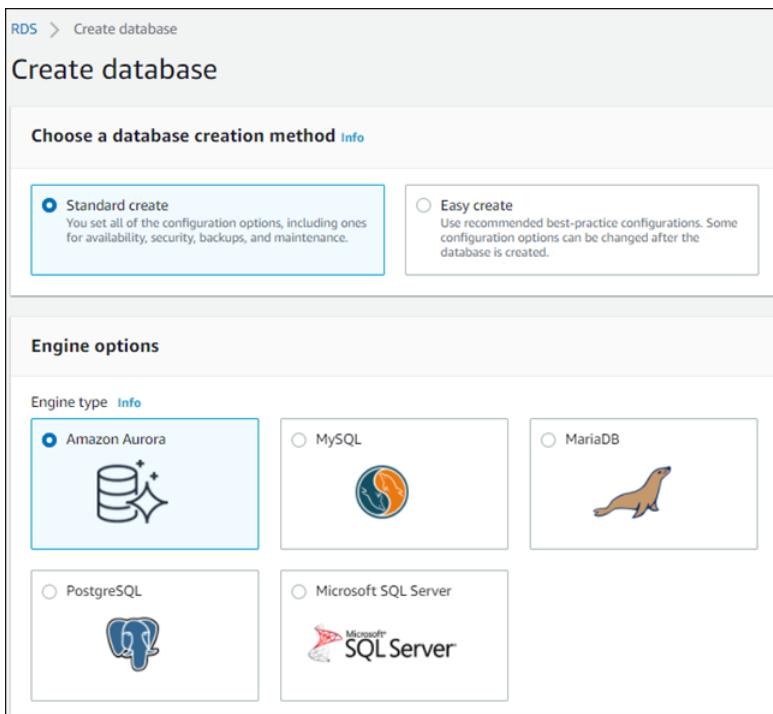

The steps for creating an Aurora global database begin by signing in to an AWS Region that supports the Aurora global database feature. For a complete list, see [Aurora global databases \(p. 21\)](#).

One of the following steps is choosing a virtual private cloud (VPC) based on Amazon VPC for your Aurora DB cluster. To use your own VPC, we recommend that you create it in advance so it's available for you to choose. At the same time, create any related subnets, and as needed a subnet group and security group. To learn how, see [How to create a VPC for use with Amazon Aurora](#).

For general information about creating an Aurora DB cluster, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

To create an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Create database**. On the **Create database** page, do the following:
 - For the database creation method, choose **Standard create**. (Don't choose Easy create.)
 - For **Engine type** in the **Engine options** section, choose **Amazon Aurora**.

Then choose **Amazon Aurora with MySQL compatibility** or **Amazon Aurora with PostgreSQL compatibility**, and continue creating your Aurora global database by using the steps from the following procedures.

Topics

- [Creating a global database using Aurora MySQL \(p. 230\)](#)
- [Creating a global database using Aurora PostgreSQL \(p. 234\)](#)

[Creating a global database using Aurora MySQL](#)

The following steps apply to all versions of Aurora MySQL except for Aurora MySQL 5.6.10a. To use Aurora MySQL 5.6.10a for your Aurora global database, see [Using Aurora MySQL 5.6.10a for an Aurora global database \(p. 233\)](#).

To create an Aurora global database using Aurora MySQL

Complete the **Create database** page.

1. For **Engine options**, choose the following:
 - a. For **Edition**, choose **Amazon Aurora with MySQL compatibility**.
 - b. For **Capacity type**, choose **Provisioned**.
 - c. Leave **Replication features** set to the default (single-master replication).
 - d. Turn on **Show versions that support the global database feature**.
 - e. For **Version**, choose the version of Aurora MySQL that you want to use for your Aurora global database.

Edition

- Amazon Aurora with MySQL compatibility
- Amazon Aurora with PostgreSQL compatibility

Capacity type [Info](#)

- Provisioned**
You provision and manage the server instance sizes.
- Serverless**
You specify the minimum and maximum amount of resources needed, and Aurora scales the capacity based on database load. This is a good option for intermittent or unpredictable workloads.

▶ Replication features [Info](#)
Single-master replication is currently selected

Engine version [Info](#)
View the engine versions that support the following database features.

- Show versions that support the global database feature
- Show versions that support the parallel query feature

Version

Aurora (MySQL 5.7) 2.07.2

To see more versions, modify the capacity types. [Info](#)

2. For **Templates**, choose **Production**. Or you can choose Dev/Test if appropriate for your use case. Don't use Dev/Test in production environments.
3. For **Settings**, do the following:
 - a. Enter a meaningful name for the DB cluster identifier. When you finish creating the Aurora global database, this name identifies the primary DB cluster.
 - b. Enter your own password for the **admin** user account for the DB instance, or have Aurora generate one for you. If you choose to autogenerated a password, you get an option to copy the password.

Settings

DB cluster identifier [Info](#)
Type a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

▼ Credentials Settings

Master username [Info](#)
Type a login ID for the master user of your DB instance.

1 to 16 alphanumeric characters. First character must be a letter

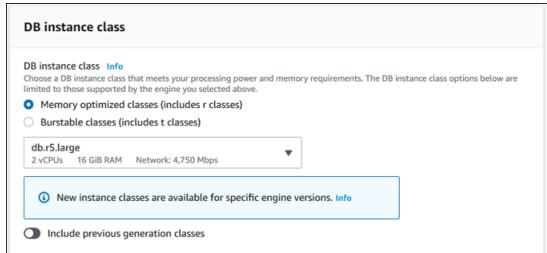

Auto generate a password
Amazon RDS can generate a password for you, or you can specify your own password

Master password [Info](#)

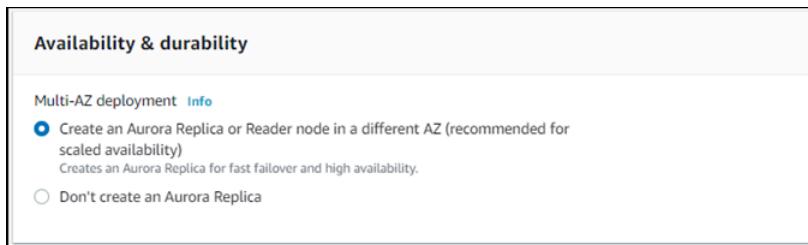

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

Confirm password [Info](#)

4. For **DB instance class**, choose **db.r5.large** or another memory optimized DB instance class. We recommend that you use a db.r5 or higher instance class.

- For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different Availability Zone (AZ) for you. If you don't create an Aurora Replica now, you need to do it later.

- For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.
- Complete the **Database authentication** settings. To simplify the process, you can choose **Password authentication** now and set up AWS Identity and Access Management (IAM) later.
- For **Additional configuration**, do the following:
 - Enter a name for **Initial database name** to create the primary Aurora DB instance for this cluster. This is the writer node for the Aurora primary DB cluster.

Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.

 - Clear the **Enable backtrack** check box if it's selected. Aurora global databases don't support backtracking. Otherwise, accept the other default settings for **Additional configuration**.
- Choose **Create database**.

It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. You can tell when the Aurora DB cluster is ready to use as the primary DB cluster in an Aurora global database by its status. When that's so, its status and that of the writer and replica node is **Available**, as shown following.

Databases						
	DB identifier	Role	Engine	Region & AZ	Size	Status
<input type="checkbox"/> Group resources <input type="button" value="Modify"/> <input type="button" value="Actions"/> <input type="button" value="Restore from S3"/> <input type="button" value="Create database"/>						
<input type="text" value="Filter databases"/>						
	lab-demo-db-cluster	Regional	Aurora PostgreSQL	us-west-1	1 instance	Available
	lab-west-db-cluster	Regional	Aurora MySQL	us-west-1	2 instances	Available
	lab-west-db-cluster-instance-1	Writer	Aurora MySQL	us-west-1b	db.r4.large	Available
	lab-west-db-cluster-instance-1-us-west-1c	Reader	Aurora MySQL	us-west-1c	db.r4.large	Available

When your primary DB cluster is available, create the Aurora global database by adding a secondary cluster to it. To do this, follow the steps in [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).

Using Aurora MySQL 5.6.10a for an Aurora global database

The following steps apply to the 5.6.10a version of Aurora MySQL only. For other versions of Aurora MySQL, see [Creating a global database using Aurora MySQL \(p. 230\)](#).

To create an Aurora global database using Aurora MySQL 5.6.10a

Complete the **Create database** page.

1. For **Engine options**, choose the following:
 - a. For **Edition**, choose **Amazon Aurora with MySQL compatibility**.
 - b. For **Capacity type**, choose **Provisioned**.
 - c. Leave **Replication features** set to the default (single-master replication).
 - d. Turn on **Show versions that support the global database feature**.
 - e. For **Version**, choose **Aurora (MySQL 5.6) global_10a**.
2. For **Templates**, choose **Production**.
3. For **Global database settings**, do the following:
 - a. For **Global database identifier**, enter a meaningful name.
 - b. For **Credentials Settings**, enter your own password for the `postgres` user account for the DB instance, or have Aurora generate one for you. If you choose Auto generate a password, you get an option to copy the password.

Global database settings

Settings

Global database identifier [Info](#)
Enter a name for your global database. The name must be unique across all global databases in your AWS account.
lab-ams5610a-global-database

The global database identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

▼ Credentials Settings

Master username [Info](#)
Type a login ID for the master user of your DB instance.
admin

1 to 16 alphanumeric characters. First character must be a letter

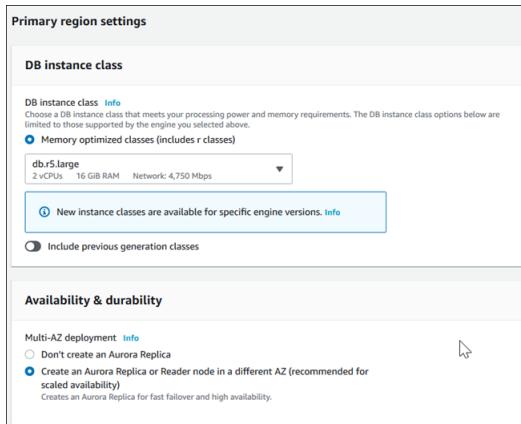

Auto generate a password
Amazon RDS can generate a password for you, or you can specify your own password

Master password [Info](#)
.....

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

Confirm password [Info](#)
.....

4. For **Encryption**, enable or disable encryption as needed.
5. The remaining sections of the **Create database** page configure the **Primary region settings**. Complete these as follows:
 - a. For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a `db.r5` or higher instance class.

- b. For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different AZ for you. If you don't create an Aurora Replica now, you need to do it later.
- c. For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.
- d. For **Encryption key**, choose the key to use. If you didn't choose **Encryption** earlier, disregard this option.
- e. Complete the **Database authentication** settings. To simplify the process, you can choose **Password authentication** now and set up IAM later.
- f. For **Additional configuration**, do the following:
 - i. For **DB instance identifier**, enter a name for the database instance, or use the default provided. This is the writer instance for the Aurora primary DB cluster for this Aurora global database.
 - ii. For **DB cluster identifier**, enter a meaningful name or accept the default provided.
 - iii. Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.
 - iv. You can accept all other default settings for **Additional configuration**.
- g. Choose **Create database**.

It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. You can tell when the Aurora DB cluster is ready to use as the primary DB cluster in an Aurora global database by its status. When that's so, its status and that of the writer and replica node is **Available**, as shown following.

		Global	Aurora MySQL	1 region	1 cluster
<input type="radio"/>	lab-ams5610a-global-database	Global	Aurora MySQL	1 region	1 cluster
<input type="radio"/>	lab-ams5610a-global-database-cluster-1	Primary	Aurora MySQL	us-west-1	2 instances
<input type="radio"/>	lab-ams5610a-global-database-instance-1	Reader	Aurora MySQL	us-west-1b	db.r4.large
<input type="radio"/>	lab-ams5610a-global-database-instance-1-us-west-1c	Reader	Aurora MySQL	us-west-1c	db.r4.large

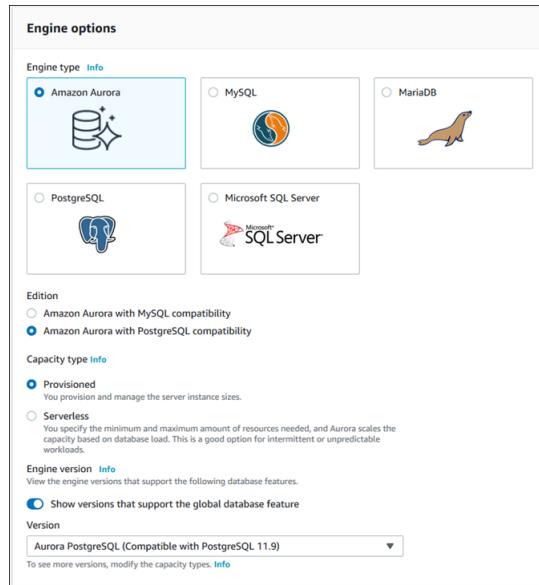

This Aurora global database still needs a secondary Aurora DB cluster. You can add that now, by following the steps in [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).

Creating a global database using Aurora PostgreSQL

To create an Aurora global database using Aurora PostgreSQL

Complete the **Create database** page.

1. For **Engine options**, choose the following:
 - a. For **Edition**, choose **Amazon Aurora with PostgreSQL compatibility**.
 - b. For **Capacity type**, choose **Provisioned**.
 - c. Turn on **Show versions that support the global database feature**.
 - d. For **Version**, choose the version of Aurora PostgreSQL that you want to use for your Aurora global database.

2. For **Templates**, choose **Production**. Or you can choose Dev/Test if appropriate. Don't use Dev/Test in production environments.
3. For **Settings**, do the following:
 - a. Enter a meaningful name for the DB cluster identifier. When you finish creating the Aurora global database, this name identifies the primary DB cluster.
 - b. Enter your own password for the default admin account for the DB cluster, or have Aurora generate one for you. If you choose Auto generate a password, you get an option to copy the password.

Settings

DB cluster identifier [Info](#)
Type a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Credentials Settings

Master username [Info](#)
Type a login ID for the master user of your DB instance.

1 to 16 alphanumeric characters. First character must be a letter

Auto generate a password
Amazon RDS can generate a password for you, or you can specify your own password

Master password [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), {single quote), "(double quote) and @ (at sign).

Confirm password [Info](#)

- For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a `db.r5` or higher instance class.

DB instance class

DB instance class [Info](#)
Choose a DB instance class that meets your processing power and memory requirements. The DB instance class options below are limited to those supported by the engine you selected above.

Memory optimized classes (includes r classes)
 Burstable classes (includes t classes)

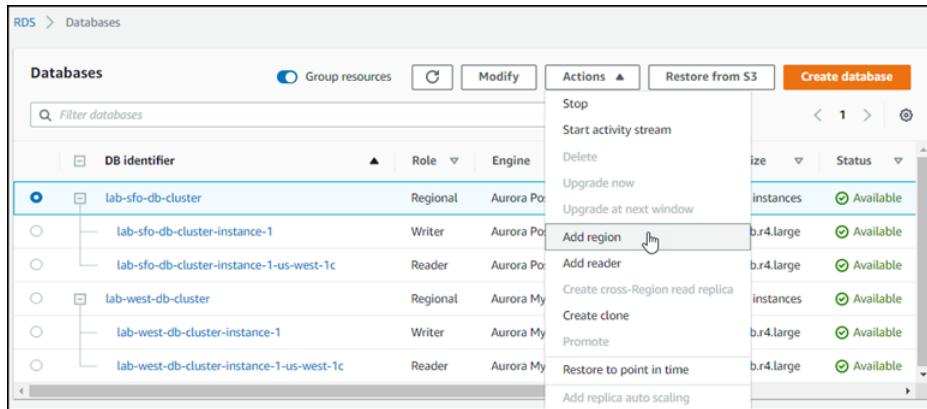

db.r5.large
2 vCPUs - 16 GiB RAM - Network: 4,750 Mbps

[New instance classes are available for specific engine versions. Info](#)

Include previous generation classes

- For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different AZ for you. If you don't create an Aurora Replica now, you need to do it later.
- For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.
- Complete the **Database authentication** settings. To simplify the process, you can choose **Password authentication** now and set up IAM or password and Kerberos authentication later.
- For **Additional configuration**, do the following:
 - Enter a name for **Initial database name** to create the primary Aurora DB instance for this cluster. This is the writer node for the Aurora primary DB cluster.
Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.
 - Accept all other default settings for **Additional configuration**, such as Monitoring, Log exports, and so on.
- Choose **Create database**.

It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. When the cluster is ready to use, the Aurora DB cluster and its writer and replica nodes display **Available** status. This becomes the primary DB cluster of your Aurora global database, after you add a secondary.

When your primary DB cluster is available, create one or more secondary clusters by following the steps in [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).

AWS CLI

The AWS CLI commands in the procedures following accomplish the following tasks:

1. Create an Aurora global database, giving it a name and specifying the Aurora database engine type that you plan to use.
2. Create an Aurora DB cluster for the Aurora global database.
3. Create the Aurora DB instance for the cluster.
4. Create an Aurora DB instance for the Aurora DB cluster.
5. Create a second DB instance for Aurora DB cluster. This is a reader to complete the Aurora DB cluster.
6. Create a second Aurora DB cluster in another Region and then add it to your Aurora global database, by following the steps in [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).

Follow the procedure for your Aurora database engine.

CLI examples

- [Creating a global database using Aurora MySQL \(p. 165\)](#)
- [Creating a global database using Aurora PostgreSQL \(p. 166\)](#)

[Creating a global database using Aurora MySQL](#)

To create an Aurora global database using Aurora MySQL

1. Use the `create-global-cluster` CLI command, passing the name of the AWS Region, Aurora database engine and version. Choose your parameters from those shown in the table for the version of Aurora MySQL that you want to use.

Other options for Aurora MySQL depend on the version of the Aurora MySQL database engine, as shown in the following table.

Parameter	Aurora MySQL version 1	Aurora MySQL version 2 and 3
<code>--engine</code>	<code>aurora</code>	<code>aurora-mysql</code>
<code>--engine-mode</code>	<code>global</code>	-

Parameter	Aurora MySQL version 1	Aurora MySQL version 2 and 3
--engine-version	5.6.10a, 5.6.mysql_aurora.1.22.0, 5.7.mysql_aurora.2.07.1, 5.6.mysql_aurora.1.22.1, 5.7.mysql_aurora.2.07.2, 5.6.mysql_aurora.1.22.2, 5.7.mysql_aurora.2.07.3, 5.6.mysql_aurora.1.22.3, 5.7.mysql_aurora.2.08.0, 5.6.mysql_aurora.1.23.0, 5.7.mysql_aurora.2.08.1, 5.6.mysql_aurora.1.23.1, 5.7.mysql_aurora.2.08.1, and later versions	5.7.mysql_aurora.2.07.0, 5.7.mysql_aurora.2.08.3, 5.7.mysql_aurora.2.09.0, 5.7.mysql_aurora.2.08.1, and later versions; 8.0.mysql_aurora.3.01.0 and later versions

For Linux, macOS, or Unix:

```
aws rds create-global-cluster --region primary_region \
    --global-cluster-identifier global_database_id \
    --engine aurora \
    --engine-version version # optional
```

For Windows:

```
aws rds create-global-cluster ^
    --global-cluster-identifier global_database_id ^
    --engine aurora ^
    --engine-version version # optional
```

This creates an "empty" Aurora global database, with just a name (identifier) and Aurora database engine. It can take a few minutes for the Aurora global database to be available. Before going to the next step, use the [describe-global-clusters](#) CLI command to see if it's available.

```
aws rds describe-global-clusters --region primary_region --global-cluster-
    identifier global_database_id
```

When the Aurora global database is available, you can create its primary Aurora DB cluster.

2. To create a primary Aurora DB cluster, use the [create-db-cluster](#) CLI command. Include the name of your Aurora global database by using the `--global-cluster-identifier`.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
    --region primary_region \
    --db-cluster-identifier db_cluster_id \
    --master-username userid \
    --master-user-password password \
    --engine { aurora | aurora-mysql } \
    --engine-mode global # Required for --engine-version 5.6.10a only \
    --engine-version version \
    --global-cluster-identifier global_database_id
```

For Windows:

```
aws rds create-db-cluster ^
--region primary_region ^
--db-cluster-identifier db_cluster_id ^
--master-username userid ^
--master-user-password password ^
--engine { aurora | aurora-mysql } ^
--engine-mode global # Required for --engine-version 5.6.10a only ^
--engine-version version ^
--global-cluster-identifier global_database_id
```

Other options for Aurora MySQL depend on the version of the Aurora MySQL database engine.

Use the [describe-db-clusters](#) AWS CLI command to confirm that the Aurora DB cluster is ready. To single out a specific Aurora DB cluster, use `--db-cluster-identifier` parameter. Or you can leave out the Aurora DB cluster name in the command to get details about all your Aurora DB clusters in the given Region.

```
aws rds describe-db-clusters --region primary_region --db-cluster-
identifier db_cluster_id
```

When the response shows "Status": "available" for the cluster, it's ready to use.

3. Create the DB instance for your primary Aurora DB cluster. To do so, use the [create-db-instance](#) CLI command. Give the command your Aurora DB cluster's name, and specify the configuration details for the instance. You don't need to pass the `--master-username` and `--master-user-password` parameters in the command, because it gets those from the Aurora DB cluster.

For the `--db-instance-class`, you can use only those from the memory optimized classes, such as `db.r5.large`. We recommend that you use a `db.r5` or higher instance class. For information about these classes, see [DB instance classes](#).

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-cluster-identifier db_cluster_id \
--db-instance-class instance_class \
--db-instance-identifier db_instance_id \
--engine { aurora | aurora-mysql } \
--engine-mode global # Required for --engine-version 5.6.10a only \
--engine-version version \
--region primary_region
```

For Windows:

```
aws rds create-db-instance ^
--db-cluster-identifier db_cluster_id ^
--db-instance-class instance_class ^
--db-instance-identifier db_instance_id ^
--engine { aurora | aurora-mysql } ^
--engine-mode global # Required for --engine-version 5.6.10a only ^
--engine-version version ^
--region primary_region
```

The `create-db-instance` operation might take some time to complete. Check the status to see if the Aurora DB instance is available before continuing.

```
aws rds describe-db-clusters --db-cluster-identifier sample_secondary_db_cluster
```

When the command returns a status of "available," you can create another Aurora DB instance for your primary DB cluster. This is the reader instance (the Aurora Replica) for the Aurora DB cluster.

4. To create another Aurora DB instance for the cluster, use the [create-db-instance](#) CLI command.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-cluster-identifier sample_secondary_db_cluster \
--db-instance-class instance_class \
--db-instance-identifier sample_replica_db \
--engine aurora
```

For Windows:

```
aws rds create-db-instance ^
--db-cluster-identifier sample_secondary_db_cluster ^
--db-instance-class instance_class ^
--db-instance-identifier sample_replica_db ^
--engine aurora
```

When the DB instance is available, replication begins from the writer node to the replica. Before continuing, check that the DB instance is available with the [describe-db-instances](#) CLI command.

At this point, you have an Aurora global database with its primary Aurora DB cluster containing a writer DB instance and an Aurora Replica. You can now add a read-only Aurora DB cluster in a different Region to complete your Aurora global database. To do so, follow the steps in [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).

Creating a global database using Aurora PostgreSQL

When you create Aurora objects for an Aurora global database by using the following commands, it can take a few minutes for each to become available. We recommend that after completing any given command, you check the specific Aurora object's status to make sure that the status is available.

To do so, use the [describe-global-clusters](#) CLI command.

```
aws rds describe-global-clusters --region primary_region
--global-cluster-identifier global_database_id
```

To create an Aurora global database using Aurora PostgreSQL

1. Use the [create-global-cluster](#) CLI command.

For Linux, macOS, or Unix:

```
aws rds create-global-cluster --region primary_region \
--global-cluster-identifier global_database_id \
--engine aurora-postgresql \
--engine-version version # optional
```

For Windows:

```
aws rds create-global-cluster ^
--global-cluster-identifier global_database_id ^
--engine aurora-postgresql ^
--engine-version version # optional
```

When the Aurora global database is available, you can create its primary Aurora DB cluster.

2. To create a primary Aurora DB cluster, use the [create-db-cluster](#) CLI command. Include the name of your Aurora global database by using the `--global-cluster-identifier`.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
  --region primary_region \
  --db-cluster-identifier db_cluster_id \
  --master-username userid \
  --master-user-password password \
  --engine aurora-postgresql \
  --engine-version version \
  --global-cluster-identifier global_database_id
```

For Windows:

```
aws rds create-db-cluster ^
  --region primary_region ^
  --db-cluster-identifier db_cluster_id ^
  --master-username userid ^
  --master-user-password password ^
  --engine aurora-postgresql ^
  --engine-version version ^
  --global-cluster-identifier global_database_id
```

Check that the Aurora DB cluster is ready. When the response from the following command shows "Status": "available" for the Aurora DB cluster, you can continue.

```
aws rds describe-db-clusters --region primary_region --db-cluster-
  identifier db_cluster_id
```

3. Create the DB instance for your primary Aurora DB cluster. To do so, use the [create-db-instance](#) CLI command.

- Pass the name of your Aurora DB cluster with the `--db-instance-identifier` parameter.

You don't need to pass the `--master-username` and `--master-user-password` parameters in the command, because it gets those from the Aurora DB cluster.

For the `--db-instance-class`, you can use only those from the memory optimized classes, such as `db.r5.large`. We recommend that you use a `db.r5` or higher instance class. For information about these classes, see [DB instance classes](#).

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-cluster-identifier db_cluster_id \
  --db-instance-class instance_class \
  --db-instance-identifier db_instance_id \
  --engine aurora-postgresql \
  --engine-version version \
  --region primary_region
```

For Windows:

```
aws rds create-db-instance ^
```

```
--db-cluster-identifier db_cluster_id ^
--db-instance-class instance_class ^
--db-instance-identifier db_instance_id ^
--engine aurora-postgresql ^
--engine-version version ^
--region primary_region
```

4. Check the status of the Aurora DB instance before continuing.

```
aws rds describe-db-clusters --db-cluster-identifier sample_secondary_db_cluster
```

If the response shows that Aurora DB instance status is "available," you can create another Aurora DB instance for your primary DB cluster.

5. To create an Aurora Replica for Aurora DB cluster, use the [create-db-instance](#) CLI command.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-cluster-identifier sample_secondary_db_cluster \
--db-instance-class instance_class \
--db-instance-identifier sample_replica_db \
--engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^
--db-cluster-identifier sample_secondary_db_cluster ^
--db-instance-class instance_class ^
--db-instance-identifier sample_replica_db ^
--engine aurora-postgresql
```

When the DB instance is available, replication begins from the writer node to the replica. Before continuing, check that the DB instance is available with the [describe-db-instances](#) CLI command.

Your Aurora global database exists, but it has only its primary Region with an Aurora DB cluster made up of a writer DB instance and an Aurora Replica. You can now add a read-only Aurora DB cluster in a different Region to complete your Aurora global database. To do so, follow the steps in [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).

RDS API

To create an Aurora global database with the RDS API, run the [CreateGlobalCluster](#) operation.

Adding an AWS Region to an Amazon Aurora global database

An Aurora global database needs at least one secondary Aurora DB cluster in a different AWS Region than the primary Aurora DB cluster. You can attach up to five secondary DB clusters to your Aurora global database. For each secondary DB cluster that you add to your Aurora global database, reduce the number of Aurora Replicas allowed to the primary DB cluster by one.

For example, if your Aurora global database has 5 secondary Regions, your primary DB cluster can have only 10 (rather than 15) Aurora Replicas. For more information, see [Configuration requirements of an Amazon Aurora global database \(p. 228\)](#).

The number of Aurora Replicas (reader instances) in the primary DB cluster determines the number of secondary DB clusters you can add. The total number of reader instances in the primary DB cluster

plus the number of secondary clusters can't exceed 15. For example, if you have 14 reader instances in the primary DB cluster and 1 secondary cluster, you can't add another secondary cluster to the global database.

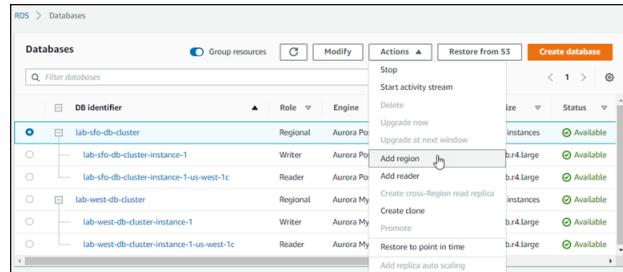

Note

For Aurora MySQL version 3, when you create a secondary cluster, make sure that the value of `lower_case_table_names` matches the value in the primary cluster. This setting is a database parameter that affects how the server handles identifier case sensitivity. For more information about database parameters, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#).

Console

To add an AWS Region to an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane of the AWS Management Console, choose **Databases**.
3. Choose the Aurora global database that needs a secondary Aurora DB cluster. Ensure that the primary Aurora DB cluster is Available.
4. For **Actions**, choose **Add region**.

5. On the **Add a region** page, choose the secondary AWS Region.

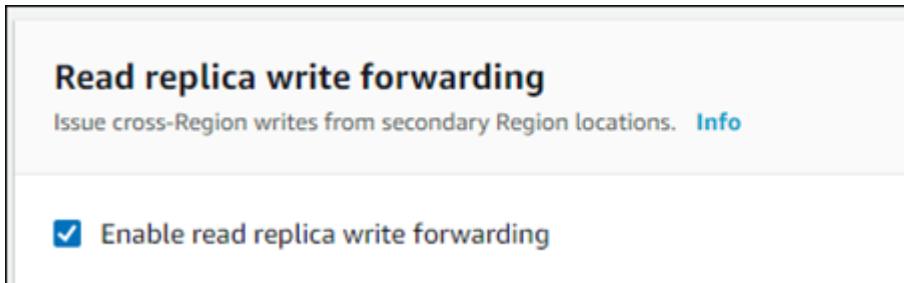

You can't choose an AWS Region that already has a secondary Aurora DB cluster for the same Aurora global database. Also, it can't be the same Region as the primary Aurora DB cluster.

The screenshot shows the 'Add a region' configuration page. It includes sections for 'Global database settings' and 'Region'.

- Global database settings:**
 - Global database identifier:** The input field contains 'lab-east-west-global'.
 - A note below states: 'The global database identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.'
- Region:**
 - Secondary region:** The dropdown menu shows 'US East (N. Virginia)'.

6. Complete the remaining fields for the secondary Aurora cluster in the new AWS Region. These are the same configuration options as for any Aurora DB cluster instance, except for the following option for Aurora MySQL-based Aurora global databases only:

- Enable read replica write forwarding – This optional setting lets your Aurora global database's secondary DB clusters forward write operations to the primary cluster. For more information, see [Using write forwarding in an Amazon Aurora global database \(p. 255\)](#).

7. Add region.

After you finish adding the Region to your Aurora global database, you can see it in the list of **Databases** in the AWS Management Console as shown in the screenshot.

Databases		Group resources		Modify	Actions ▾	Restore from S3
		Filter databases				
	DB identifier	Role	Engine	Region & AZ	Size	▼
○	lab-east-west-global	Global	Aurora PostgreSQL	2 regions	2 clusters	
○	lab-sfo-db-cluster	Primary	Aurora PostgreSQL	us-west-1	2 instances	
○	lab-sfo-db-cluster-instance-1	Writer	Aurora PostgreSQL	us-west-1b	db.r4.large	
○	lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large	
○	lab-east-coast-db-cluster	Secondary	Aurora PostgreSQL	us-east-1	2 instances	
○	lab-east-coast-db-instance	Reader	Aurora PostgreSQL	us-east-1b	db.r4.large	
○	lab-east-coast-db-instance-us-east-1c	Reader	Aurora PostgreSQL	us-east-1c	db.r4.large	

AWS CLI

To add a secondary AWS Region to an Aurora global database

1. Use the `create-db-cluster` CLI command with the name (`--global-cluster-identifier`) of your Aurora global database. For other parameters, do the following:
 2. For `--region`, choose a different AWS Region than that of your Aurora primary Region.
 3. Do one of the following:
 - For an Aurora global database based on Aurora MySQL 5.6.10a only, use the following parameters:
 - `--engine - aurora`
 - `--engine-mode - global`
 - `--engine-version - 5.6.10a`

- For an Aurora global database based on other Aurora DB engines, choose specific values for the `--engine` and `--engine-version` parameters. These values are the same as those for the primary Aurora DB cluster in your Aurora global database.

The following table displays current options.

Parameter	Aurora MySQL 5.6	Aurora MySQL 5.7	Aurora PostgreSQL
<code>--engine</code>	aurora	aurora-mysql	aurora-postgresql
<code>--engine-version</code>	5.6.mysql_aurora.1.22.0, 5.6.mysql_aurora.1.22.1, 5.6.mysql_aurora.1.22.2, 5.6.mysql_aurora.1.22.3, 5.6.mysql_aurora.1.23.0, 5.6.mysql_aurora.1.23.1	5.7.mysql_aurora.2.07.0, 5.7.mysql_aurora.2.07.1, 5.7.mysql_aurora.2.07.2, 5.7.mysql_aurora.2.07.3, 5.7.mysql_aurora.2.08.0, 5.7.mysql_aurora.2.08.1, 5.7.mysql_aurora.2.08.2, 5.7.mysql_aurora.2.08.3, 5.7.mysql_aurora.2.09.0 (and later)	10.11 (and later), 11.7 (and later), 12.4 (and later)

- For an encrypted cluster, specify your primary AWS Region as the `--source-region` for encryption.

The following example creates a new Aurora DB cluster and attaches it to an Aurora global database as a read-only secondary Aurora DB cluster. In the last step, an Aurora DB instance is added to the new Aurora DB cluster.

For Linux, macOS, or Unix:

```
aws rds --region secondary_region \
create-db-cluster \
--db-cluster-identifier secondary_cluster_id \
--global-cluster-identifier global_database_id \
--engine { aurora | aurora-mysql | aurora-postgresql } \
--engine-version version

aws rds --region secondary_region \
create-db-instance \
--db-instance-class instance_class \
--db-cluster-identifier secondary_cluster_id \
--db-instance-identifier db_instance_id \
--engine { aurora | aurora-mysql | aurora-postgresql }
```

For Windows:

```
aws rds --region secondary_region ^
create-db-cluster ^
--db-cluster-identifier secondary_cluster_id ^
--global-cluster-identifier global_database_id_id ^
--engine { aurora | aurora-mysql | aurora-postgresql } ^
--engine-version version

aws rds --region secondary_region ^
create-db-instance ^
--db-instance-class instance_class ^
--db-cluster-identifier secondary_cluster_id ^
--db-instance-identifier db_instance_id ^
--engine { aurora | aurora-mysql | aurora-postgresql }
```

RDS API

To add a new AWS Region to an Aurora global database with the RDS API, run the [CreateDBCluster](#) operation. Specify the identifier of the existing global database using the `GlobalClusterIdentifier` parameter.

Creating a headless Aurora DB cluster in a secondary Region

Although an Aurora global database requires at least one secondary Aurora DB cluster in a different AWS Region than the primary, you can use a *headless* configuration for the secondary cluster. A headless secondary Aurora DB cluster is one without a DB instance. This type of configuration can lower expenses for an Aurora global database. In an Aurora DB cluster, compute and storage are decoupled. Without the DB instance, you're not charged for compute, only for storage. If it's set up correctly, a headless secondary's storage volume is kept in-sync with the primary Aurora DB cluster.

You add the secondary cluster as you normally do when creating an Aurora global database. However, after the primary Aurora DB cluster begins replication to the secondary, you delete the Aurora read-only DB instance from the secondary Aurora DB cluster. This secondary cluster is now considered "headless" because it no longer has a DB instance. Yet, the storage volume is kept in sync with the primary Aurora DB cluster.

Warning

With Aurora PostgreSQL, to create a headless cluster in a secondary AWS Region, use the AWS CLI or RDS API to add the secondary AWS Region. Skip the step to create the reader DB instance for the secondary cluster. Currently, creating a headless cluster isn't supported in the RDS Console. For the CLI and API procedures to use, see [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).

Creating a reader DB instance in a secondary Region and subsequently deleting it could lead to an Aurora PostgreSQL vacuum issue on the primary Region's writer DB instance. If you encounter this issue, restart the primary Region's writer DB instance after you delete the secondary Region's reader DB instance.

To add a headless secondary Aurora DB cluster to your Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane of the AWS Management Console, choose **Databases**.
3. Choose the Aurora global database that needs a secondary Aurora DB cluster. Ensure that the primary Aurora DB cluster is Available.
4. For **Actions**, choose **Add region**.
5. On the **Add a region** page, choose the secondary AWS Region.

You can't choose an AWS Region that already has a secondary Aurora DB cluster for the same Aurora global database. Also, it can't be the same Region as the primary Aurora DB cluster.

6. Complete the remaining fields for the secondary Aurora cluster in the new AWS Region. These are the same configuration options as for any Aurora DB cluster instance.

For an Aurora MySQL-based Aurora global database, disregard the **Enable read replica write forwarding** option. This option has no function after you delete the reader instance.

7. **Add region.** After you finish adding the Region to your Aurora global database, you can see it in the list of **Databases** in the AWS Management Console as shown in the screenshot.

DB identifier	Role	Engine	Region & AZ	Size	Status
west-coast-global	Global	Aurora MySQL	2 regions	2 clusters	Available
ams57west	Primary	Aurora MySQL	us-west-1	2 instances	Available
ams57west-instance-1	Writer	Aurora MySQL	us-west-1b	db.r5.large	Available
ams57west-instance-1-us-west-1c	Reader	Aurora MySQL	us-west-1c	db.r5.large	Available
west-coast-global-cluster-1	Secondary	Aurora MySQL	us-west-2	1 instance	Available
west-coast-global-instance-1	Reader	Aurora MySQL	us-west-2a	db.r5.large	Available

- Check the status of the secondary Aurora DB cluster and its reader instance before continuing, by using the AWS Management Console or the AWS CLI. For example:

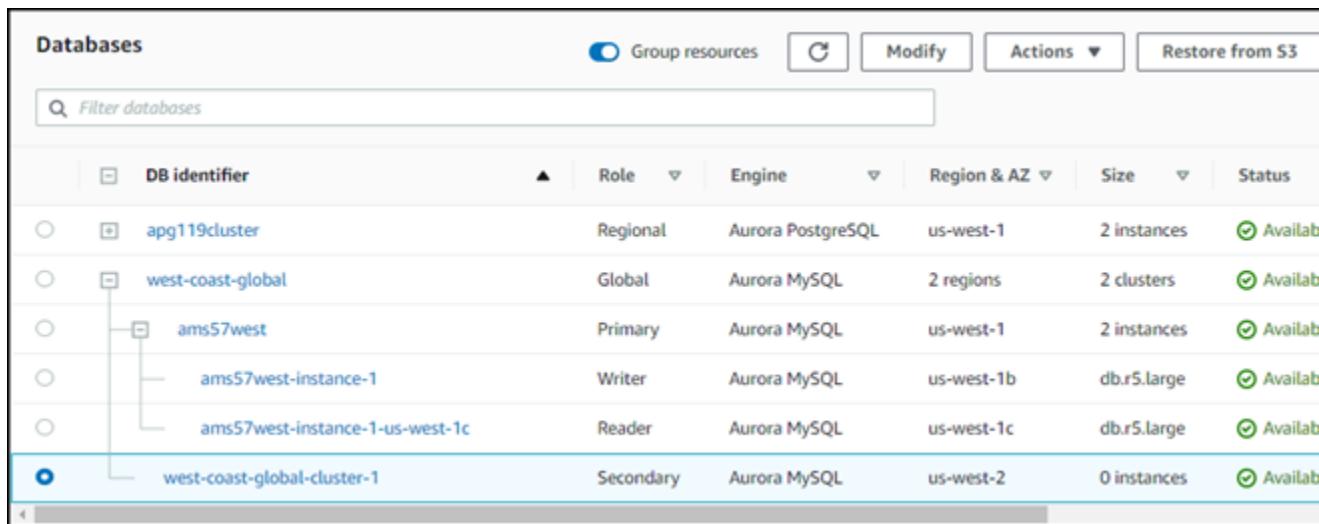

```
$ aws rds describe-db-clusters --db-cluster-identifier secondary-cluster-id --query '*[].[Status]' --output text
```

It can take several minutes for the status of a newly added secondary Aurora DB cluster to change from **creating** to **available**. When the Aurora DB cluster is available, you can delete the reader instance.

- Select the reader instance in the secondary Aurora DB cluster, and then choose **Delete**.

DB identifier	Role	Engine	Region & AZ	Size	Status
west-coast-global	Global	Aurora MySQL	2 regions	2 clusters	Available
ams57west	Primary	Aurora MySQL	us-west-1	2 instances	Available
west-coast-global-cluster-1	Secondary	Aurora MySQL	us-west-2	1 instance	Available
west-coast-global-instance-1	Reader	Aurora MySQL	us-west-2a	db.r5.large	Available

After deleting the reader instance, the secondary cluster remains part of the Aurora global database. It has no instance associated with it, as shown following.

DB identifier	Role	Engine	Region & AZ	Size	Status
apg119cluster	Regional	Aurora PostgreSQL	us-west-1	2 instances	Available
west-coast-global	Global	Aurora MySQL	2 regions	2 clusters	Available
ams57west	Primary	Aurora MySQL	us-west-1	2 instances	Available
ams57west-instance-1	Writer	Aurora MySQL	us-west-1b	db.r5.large	Available
ams57west-instance-1-us-west-1c	Reader	Aurora MySQL	us-west-1c	db.r5.large	Available
west-coast-global-cluster-1	Secondary	Aurora MySQL	us-west-2	0 instances	Available

You can use this headless secondary Aurora DB cluster to [manually recover your Amazon Aurora global database from an unplanned outage in the primary AWS Region \(p. 267\)](#) if such an outage occurs.

Using a snapshot for your Amazon Aurora global database

You can restore a snapshot of an Aurora DB cluster or from an Amazon RDS DB instance to use as the starting point for your Aurora global database. You restore the snapshot and create a new Aurora provisioned DB cluster at the same time. You then add another AWS Region to the restored DB cluster, thus turning it into an Aurora global database. Any Aurora DB cluster that you create using a snapshot in this way becomes the primary cluster of your Aurora global database.

The snapshot that you use can be from a provisioned or from a serverless Aurora DB cluster.

Note

You can't create a provisioned Aurora DB cluster from a snapshot made from an Aurora MySQL 5.6.10a-based global database. A snapshot from an Aurora MySQL 5.6.10a-based global database can only be restored as an Aurora global database.

During the restore process, choose the same DB engine type as the snapshot. For example, suppose that you want to restore a snapshot that was made from an Aurora Serverless v1 DB cluster running Aurora PostgreSQL. In this case, you create an Aurora PostgreSQL DB cluster using that same Aurora DB engine and version.

The restored DB cluster assumes the role of primary cluster for Aurora global database when you add an AWS Regions to it. All data contained in this primary cluster is replicated to any secondary clusters that you add to your Aurora global database.

RDS > Snapshots > Restore snapshot

Restore snapshot

You are creating a new DB Instance from a source DB Instance at a specified time. This new DB Instance will have the default DB Security group and DB Parameter groups.

DB specifications

Engine: Amazon Aurora with MySQL compatibility

Capacity type [Info](#)

- Provisioned
You provision and manage the server instance sizes.
- Serverless
You specify the minimum and maximum amount of resources needed, and Aurora scales the capacity based on database load. This is a good option for intermittent or unpredictable workloads.

► Replication features [Info](#)
Single-master replication is currently selected

Engine version [Info](#)
View the engine versions that support the following database features.

- Show versions that support the global database feature
- Show versions that support the parallel query feature

Version: Aurora (MySQL 5.6) 1.22.1

To see more versions, modify the capacity types. [Info](#)

Managing an Amazon Aurora global database

With the exception of the managed planned failover process, you perform most management operations on the individual clusters that make up an Aurora global database. When you choose **Group related resources** on the **Databases** page in the console, you see the primary cluster and secondary clusters grouped under the associated global database. To find the AWS Regions where a global database's DB clusters are running, its Aurora DB engine and version, and its identifier, use its **Configuration** tab.

The managed planned failover process is available to Aurora global database objects only, not for a single Aurora DB cluster. To learn more, see [Performing managed planned failovers for Amazon Aurora global databases \(p. 268\)](#).

To recover an Aurora global database from an unplanned outage in its primary Region, see [Using failover in an Amazon Aurora global database \(p. 266\)](#).

Topics

- [Modifying an Amazon Aurora global database \(p. 249\)](#)
- [Modifying parameters for an Aurora global database \(p. 250\)](#)
- [Removing a cluster from an Amazon Aurora global database \(p. 251\)](#)
- [Deleting an Amazon Aurora global database \(p. 253\)](#)

Modifying an Amazon Aurora global database

The **Databases** page in the AWS Management Console lists all your Aurora global databases, showing the primary cluster and secondary clusters for each one. The Aurora global database has its own

configuration settings. Specifically, it has AWS Regions associated with its primary and secondary clusters, as shown in the screenshot following.

DB identifier	Role	Engine	Region & AZ	Size	Status
lab-east-west-global	Global	Aurora PostgreSQL	2 regions	2 clusters	Available
lab-sfo-db-cluster	Primary	Aurora PostgreSQL	us-west-1	2 instances	Available
lab-sfo-db-cluster-instance-1	Writer	Aurora PostgreSQL	us-west-1b	db.r4.large	Available
lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large	Available
lab-east-coast-db-cluster	Secondary	Aurora PostgreSQL	us-east-1	2 instances	Available

When you make changes to the Aurora global database, you have a chance to cancel changes, as shown in the following screenshot.

Global database identifier
Enter a name for your global database. The name must be unique across all global databases in your AWS account.
lab-east-west-global-database-01

The global database identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Additional configuration

Encryption
Configure encryption keys by modifying member DB clusters.

Cancel **Continue**

When you choose **Continue**, you confirm the changes.

Modifying parameters for an Aurora global database

You can configure the Aurora DB cluster parameter groups independently for each Aurora cluster within the Aurora global database. Most parameters work the same as for other kinds of Aurora clusters. We recommend that you keep settings consistent among all the clusters in a global database. Doing this helps to avoid unexpected behavior changes if you promote a secondary cluster to be the primary.

For example, use the same settings for time zones and character sets to avoid inconsistent behavior if a different cluster takes over as the primary cluster.

The `aurora_enable_repl_bin_log_filtering` and `aurora_enable_replica_log_compression` configuration settings have no effect.

Removing a cluster from an Amazon Aurora global database

You can remove Aurora DB clusters from your Aurora global database for several different reasons. For example, you might want to remove an Aurora DB cluster from an Aurora global database if the primary cluster becomes degraded or isolated. It then becomes a standalone provisioned Aurora DB cluster that could be used to create a new Aurora global database. To learn more, see [Recovering an Amazon Aurora global database from an unplanned outage \(p. 267\)](#).

You also might want to remove Aurora DB clusters because you want to delete an Aurora global database that you no longer need. You can't delete the Aurora global database until after you remove (detach) all associated Aurora DB clusters, leaving the primary for last. For more information, see [Deleting an Amazon Aurora global database \(p. 253\)](#).

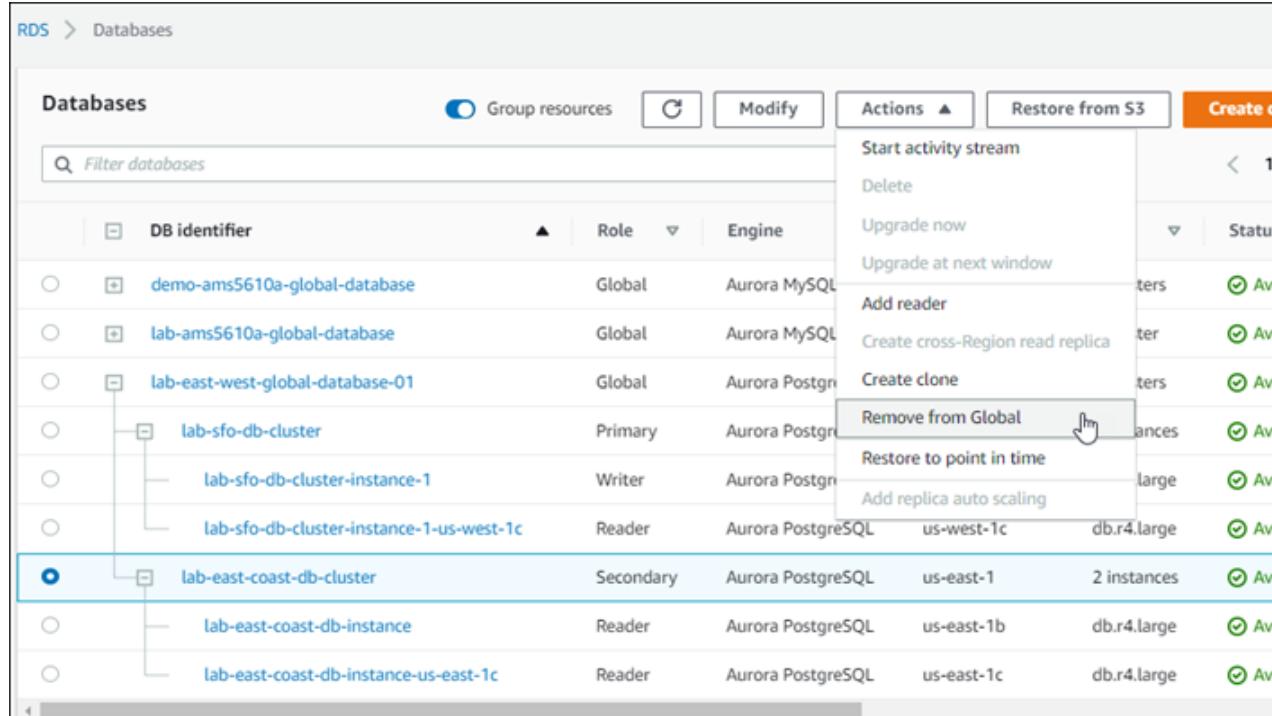

When an Aurora DB cluster is detached from the Aurora global database, it's no longer synchronized with the primary. It becomes a standalone provisioned Aurora DB cluster with full read/write capabilities.

You can remove Aurora DB clusters from your Aurora global database using the AWS Management Console, the AWS CLI, or the RDS API.

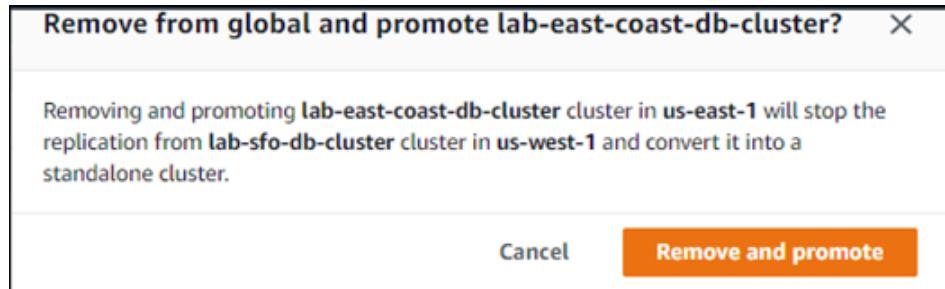

Console

To remove an Aurora cluster from an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the cluster on the **Databases** page.
3. For **Actions**, choose **Remove from Global**.

You see a prompt to confirm that you want to detach the secondary from the Aurora global database.

- Choose **Remove and promote** to remove the cluster from the global database.

The Aurora DB cluster is no longer serving as a secondary in the Aurora global database, and is no longer synchronized with the primary DB cluster. It is a standalone Aurora DB cluster with full read/write capability.

		Region	Aurora PostgreSQL	us-east-1	2 instances	
○	lab-east-coast-db-cluster	Regional	Aurora PostgreSQL	us-east-1	2 instances	
○	lab-east-coast-db-instance	Writer	Aurora PostgreSQL	us-east-1b	db.r4.large	
○	lab-east-coast-db-instance-us-east-1c	Reader	Aurora PostgreSQL	us-east-1c	db.r4.large	
○	lab-east-west-global-database-01	Global	Aurora PostgreSQL	1 region	1 cluster	
○	lab-sfo-db-cluster	Primary	Aurora PostgreSQL	us-west-1	2 instances	
○	lab-sfo-db-cluster-instance-1	Writer	Aurora PostgreSQL	us-west-1b	db.r4.large	
○	lab-sfo-db-cluster-instance-1-us-west-1c	Reader	Aurora PostgreSQL	us-west-1c	db.r4.large	

After you remove or delete all secondary clusters, then you can remove the primary cluster the same way. You can't detach (remove) the primary Aurora DB cluster from an Aurora global database until after you remove all secondary clusters.

The Aurora global database might remain in the **Databases** list, with zero Regions and AZs. You can delete if you no longer want to use this Aurora global database. For more information, see [Deleting an Amazon Aurora global database \(p. 253\)](#).

AWS CLI

To remove an Aurora cluster from an Aurora global database, run the [remove-from-global-cluster](#) CLI command with the following parameters:

- global-cluster-identifier** – The name (identifier) of your Aurora global database.
- db-cluster-identifier** – The name of each Aurora DB cluster to remove from the Aurora global database. Remove all secondary Aurora DB clusters before removing the primary.

The following examples first remove a secondary cluster and then the primary cluster from an Aurora global database.

For Linux, macOS, or Unix:

```
aws rds --region secondary_region \
    remove-from-global-cluster \
    --db-cluster-identifier secondary_cluster_ARN \
    --global-cluster-identifier global_database_id

aws rds --region primary_region \
```

```
remove-from-global-cluster \
--db-cluster-identifier primary_cluster_ARN \
--global-cluster-identifier global_database_id
```

Repeat the `remove-from-global-cluster --db-cluster-identifier secondary_cluster_ARN` command for each secondary AWS Region in your Aurora global database.

For Windows:

```
aws rds --region secondary_region ^
remove-from-global-cluster ^
--db-cluster-identifier secondary_cluster_ARN ^
--global-cluster-identifier global_database_id

aws rds --region primary_region ^
remove-from-global-cluster ^
--db-cluster-identifier primary_cluster_ARN ^
--global-cluster-identifier global_database_id
```

Repeat the `remove-from-global-cluster --db-cluster-identifier secondary_cluster_ARN` command for each secondary AWS Region in your Aurora global database.

RDS API

To remove an Aurora cluster from an Aurora global database with the RDS API, run the [RemoveFromGlobalCluster](#) action.

Deleting an Amazon Aurora global database

Because an Aurora global database typically holds business-critical data, you can't delete the global database and its associated clusters in a single step. To delete an Aurora global database, do the following:

- Remove all secondary DB clusters from the Aurora global database. Each cluster becomes a standalone Aurora DB cluster. To learn how, see [Removing a cluster from an Amazon Aurora global database \(p. 251\)](#).
- From each standalone Aurora DB cluster, delete all Aurora Replicas.
- Remove the primary DB cluster from the Aurora global database. This becomes a standalone Aurora DB cluster.
- From the Aurora primary DB cluster, first delete all Aurora Replicas, then delete the writer DB instance.

Deleting the writer instance from the newly standalone Aurora DB cluster also typically removes the Aurora DB cluster and the Aurora global database.

For more general information, see [Deleting a DB instance from an Aurora DB cluster \(p. 472\)](#).

To delete an Aurora global database, you can use the AWS Management Console, the AWS CLI, or the RDS API.

Console

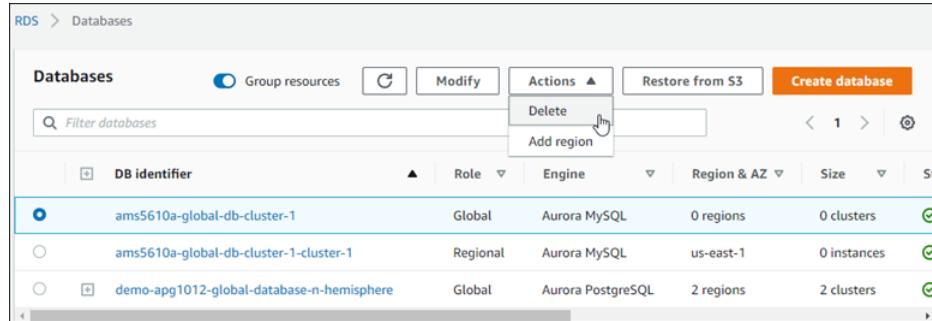

To delete an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases** and find the Aurora global database you want to delete in the listing.

3. Confirm that all clusters are removed from the Aurora global database. The Aurora global database should show 0 Regions and AZs and a size of 0 clusters.

If the Aurora global database contains any Aurora DB clusters, you can't delete it. If necessary, detach the primary and secondary Aurora DB clusters from the Aurora global database. For more information, see [Removing a cluster from an Amazon Aurora global database \(p. 251\)](#).

4. Choose your Aurora global database in the list, and then choose **Delete** from the Actions menu.

AWS CLI

To delete an Aurora global database, run the [delete-global-cluster](#) CLI command with the name of the AWS Region and the Aurora global database identifier, as shown in the following example.

For Linux, macOS, or Unix:

```
aws rds --region primary_region delete-global-cluster \
--global-cluster-identifier global_database_id
```

For Windows:

```
aws rds --region primary_region delete-global-cluster ^
--global-cluster-identifier global_database_id
```

RDS API

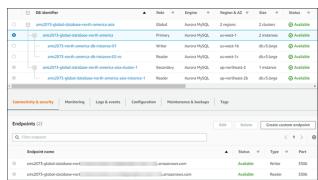

To delete a cluster that is part of an Aurora global database, run the [DeleteGlobalCluster](#) API operation.

Connecting to an Amazon Aurora global database

How you connect to an Aurora global database depends on whether you need to write to the database or read from the database:

- For read-only requests or queries, you connect to the reader endpoint for the Aurora cluster in your AWS Region.
- To run data manipulation language (DML) or data definition language (DDL) statements, you connect to the cluster endpoint for the primary cluster. This endpoint might be in a different AWS Region than your application.

When you view an Aurora global database in the console, you can see all the general-purpose endpoints associated with all of its clusters. The following screenshot shows an example. There is a single cluster endpoint associated with the primary cluster that you use for write operations. The primary cluster and each secondary cluster has a reader endpoint that you use for read-only queries. To minimize latency, choose whichever reader endpoint is in your AWS Region or the AWS Region closest to you. The following shows an Aurora MySQL example.

Using write forwarding in an Amazon Aurora global database

You can reduce the number of endpoints that you need to manage for applications running on your Aurora global database, by using *write forwarding*. This feature of Aurora MySQL lets secondary clusters in an Aurora global database forward SQL statements that perform write operations to the primary cluster. The primary cluster updates the source and then propagates resulting changes back to all secondary AWS Regions.

The write forwarding configuration saves you from implementing your own mechanism to send write operations from a secondary AWS Region to the primary Region. Aurora handles the cross-Region networking setup. Aurora also transmits all necessary session and transactional context for each statement. The data is always changed first on the primary cluster and then replicated to the secondary clusters in the Aurora global database. This way, the primary cluster is the source of truth and always has an up-to-date copy of all your data.

Note

Write forwarding requires Aurora MySQL version 2.08.1 or later.

Enabling write forwarding

By default, write forwarding isn't enabled when you add a secondary cluster to an Aurora global database.

To enable write forwarding using the AWS Management Console, choose the **Enable read replica write forwarding** option when you add a Region for a global database. For an existing secondary cluster, modify the cluster to use the **Enable read replica write forwarding** option. To turn off write forwarding, clear the **Enable read replica write forwarding** check box when adding the Region or modifying the secondary cluster.

To enable write forwarding using the AWS CLI, use the `--enable-global-write-forwarding` option. This option works when you create a new secondary cluster using the `create-db-cluster` command. It also works when you modify an existing secondary cluster using the `modify-db-cluster` command. It requires that the global database uses an Aurora version that supports write forwarding. You can turn write forwarding off by using the `--no-enable-global-write-forwarding` option with these same CLI commands.

To enable write forwarding using the Amazon RDS API, set the `EnableGlobalWriteForwarding` parameter to `true`. This parameter works when you create a new secondary cluster using the `CreateDBCluster` operation. It also works when you modify an existing secondary cluster using the `ModifyDBCluster` operation. It requires that the global database uses an Aurora version that supports write forwarding. You can turn write forwarding off by setting the `EnableGlobalWriteForwarding` parameter to `false`.

Note

For a database session to use write forwarding, you also specify a setting for the `aurora_replica_read_consistency` configuration parameter. Do this in every session that uses the write forwarding feature. For information about this parameter, see [Isolation and consistency for write forwarding \(p. 259\)](#).

The following CLI examples show how you can set up an Aurora global database with write forwarding enabled or disabled. The highlighted items represent the commands and options that are important to specify and keep consistent when setting up the infrastructure for an Aurora global database.

The following example creates an Aurora global database, a primary cluster, and a secondary cluster with write forwarding enabled. Substitute your own choices for the user name, password, and primary and secondary AWS Regions.

```
# Create overall global database.  
aws rds create-global-cluster --global-cluster-identifier write-forwarding-test \  
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \  
  --region us-east-1  
  
# Create primary cluster, in the same AWS Region as the global database.  
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \  
  --db-cluster-identifier write-forwarding-test-cluster-1 \  
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \  
  --master-username my_user_name --master-user-password my_password \  
  --region us-east-1  
  
aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-1 \  
  --db-instance-identifier write-forwarding-test-cluster-1-instance-1 \  
  --db-instance-class db.r5.large \  
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \  
  --region us-east-1  
  
aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-1 \  
  --db-instance-identifier write-forwarding-test-cluster-1-instance-2 \  
  --db-instance-class db.r5.large \  
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \  
  --region us-east-1  
  
# Create secondary cluster, in a different AWS Region than the global database,  
# with write forwarding enabled.  
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \  
  --db-cluster-identifier write-forwarding-test-cluster-2 \  
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \  
  --region us-east-2 \  
  --enable-global-write-forwarding  
  
aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \  
  --db-instance-identifier write-forwarding-test-cluster-2-instance-1 \  
  --db-instance-class db.r5.large \  
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \  
  --region us-east-2  
  
aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \  
  --db-instance-identifier write-forwarding-test-cluster-2-instance-2 \  
  --db-instance-class db.r5.large \  
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
```

```
--region us-east-2
```

The following example continues from the previous one. It creates a secondary cluster without write forwarding enabled, then enables write forwarding. After this example finishes, all secondary clusters in the global database have write forwarding enabled.

```
# Create secondary cluster, in a different AWS Region than the global database,
# without write forwarding enabled.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
--db-cluster-identifier write-forwarding-test-cluster-2 \
--engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
--region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
--db-instance-identifier write-forwarding-test-cluster-2-instance-1 \
--db-instance-class db.r5.large \
--engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
--region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
--db-instance-identifier write-forwarding-test-cluster-2-instance-2 \
--db-instance-class db.r5.large \
--engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
--region us-west-1

aws rds modify-db-cluster --db-cluster-identifier write-forwarding-test-cluster-2 \
--region us-east-2 \
--enable-global-write-forwarding
```

Checking if a secondary cluster has write forwarding enabled

To determine whether you can use write forwarding from a secondary cluster, you can check whether the cluster has the attribute "GlobalWriteForwardingStatus": "enabled".

In the AWS Management Console, you see Read replica write forwarding on the **Configuration** tab of the details page for the cluster. To see the status of the global write forwarding setting for all of your clusters, run the following AWS CLI command.

A secondary cluster shows the value "enabled" or "disabled" to indicate if write forwarding is turned on or off. A value of null indicates that write forwarding isn't available for that cluster. Either the cluster isn't part of a global database, or is the primary cluster instead of a secondary cluster. The value can also be "enabling" or "disabling" if write forwarding is in the process of being turned on or off.

Example

```
aws rds describe-db-clusters --query '*[].
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus}'
[
  {
    "GlobalWriteForwardingStatus": "enabled",
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
  },
  {
    "GlobalWriteForwardingStatus": "disabled",
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-2"
  },
  {
    "GlobalWriteForwardingStatus": null,
    "DBClusterIdentifier": "non-global-cluster"
  }
]
```

To find all secondary clusters that have global write forwarding enabled, run the following command. This command also returns the cluster's reader endpoint. You use the secondary cluster's reader endpoint to when you use write forwarding from the secondary to the primary in your Aurora global database.

Example

```
aws rds describe-db-clusters --query 'DBClusters[].  
{DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus,ReaderEndpoint:ReaderEndpoint  
| [?GlobalWriteForwardingStatus == `enabled`]}  
[  
 {  
     "GlobalWriteForwardingStatus": "enabled",  
     "ReaderEndpoint": "aurora-write-forwarding-test-replica-1.cluster-ro-cnpexample.us-west-2.rds.amazonaws.com",  
     "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"  
 }  
]
```

Application and SQL compatibility with write forwarding

Certain statements aren't allowed or can produce stale results when you use them in a global database with write forwarding. Thus, the `EnableGlobalWriteForwarding` setting is turned off by default for secondary clusters. Before turning it on, check to make sure that your application code isn't affected by any of these restrictions.

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as `INSERT`, `DELETE`, and `UPDATE`. There are some restrictions on the properties of these statements that you can use with write forwarding, as described following.
- `SELECT ... LOCK IN SHARE MODE` and `SELECT FOR UPDATE` statements.
- `PREPARE` and `EXECUTE` statements.

The following restrictions apply to the SQL statements you use with write forwarding. In some cases, you can use the statements on secondary clusters with write forwarding enabled at the cluster level. This approach works if write forwarding isn't turned on within the session by the `aurora_replica_read_consistency` configuration parameter. Trying to use a statement when it's not allowed because of write forwarding causes an error message with the following format.

```
ERROR 1235 (42000): This version of MySQL doesn't yet support 'operation with write forwarding'.
```

Data definition language (DDL)

Connect to the primary cluster to run DDL statements.

Updating a permanent table using data from a temporary table

You can use temporary tables on secondary clusters with write forwarding enabled. However, you can't use a DML statement to modify a permanent table if the statement refers to a temporary table. For example, you can't use an `INSERT ... SELECT` statement that takes the data from a temporary table. The temporary table exists on the secondary cluster and isn't available when the statement runs on the primary cluster.

XA transactions

You can't use the following statements on a secondary cluster when write forwarding is turned on within the session. You can use these statements on secondary clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting

is empty. Before turning on write forwarding within a session, check if your code uses these statements.

```
XA {START|BEGIN} xid [JOIN|RESUME]  
XA END xid [SUSPEND [FOR MIGRATE]]  
XA PREPARE xid  
XA COMMIT xid [ONE PHASE]  
XA ROLLBACK xid  
XA RECOVER [CONVERT XID]
```

LOAD statements for permanent tables

You can't use the following statements on a secondary cluster with write forwarding enabled.

```
LOAD DATA INFILE 'data.txt' INTO TABLE t1;  
LOAD XML LOCAL INFILE 'test.xml' INTO TABLE t1;
```

You can load data into a temporary table on a secondary cluster. However, make sure that you run any LOAD statements that refer to permanent tables only on the primary cluster.

Plugin statements

You can't use the following statements on a secondary cluster with write forwarding enabled.

```
INSTALL PLUGIN example SONAME 'ha_example.so';  
UNINSTALL PLUGIN example;
```

SAVEPOINT statements

You can't use the following statements on a secondary cluster when write forwarding is turned on within the session. You can use these statements on secondary clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is blank. Check if your code uses these statements before turning on write forwarding within a session.

```
SAVEPOINT t1_save;  
ROLLBACK TO SAVEPOINT t1_save;  
RELEASE SAVEPOINT t1_save;
```

Isolation and consistency for write forwarding

In sessions that use write forwarding, you can only use the `REPEATABLE READ` isolation level. Although you can also use the `READ COMMITTED` isolation level with read-only clusters in secondary AWS Regions, that isolation level doesn't work with write forwarding. For information about the `REPEATABLE READ` and `READ COMMITTED` isolation levels, see [Aurora MySQL isolation levels \(p. 1070\)](#).

You can control the degree of read consistency on a secondary cluster. The read consistency level determines how much waiting the secondary cluster does before each read operation to ensure that some or all changes are replicated from the primary cluster. You can adjust the read consistency level to ensure that all forwarded write operations from your session are visible in the secondary cluster before any subsequent queries. You can also use this setting to ensure that queries on the secondary cluster always see the most current updates from the primary cluster. This is so even for those submitted by other sessions or other clusters. To specify this type of behavior for your application, you choose a value for the session-level parameter `aurora_replica_read_consistency`.

Important

Always set the `aurora_replica_read_consistency` parameter for any session for which you want to forward writes. If you don't, Aurora doesn't enable write forwarding for that session. This parameter has an empty value by default, so choose a specific value when you use

this parameter. The `aurora_replica_read_consistency` parameter has an effect only on secondary clusters that have write forwarding enabled.

For the `aurora_replica_read_consistency` parameter, you can specify the values `EVENTUAL`, `SESSION`, and `GLOBAL`.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between AWS Regions. You can choose the balance between fast response time and ensuring that changes made in other locations are fully available before your queries run.

With the read consistency set to `EVENTUAL`, queries in a secondary AWS Region that uses write forwarding might see data that is slightly stale due to replication lag. Results of write operations in the same session aren't visible until the write operation is performed on the primary Region and replicated to the current Region. The query doesn't wait for the updated results to be available. Thus, it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag.

With the read consistency set to `SESSION`, all queries in a secondary AWS Region that uses write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated to the current Region. It doesn't wait for updated results from write operations performed in other Regions or in other sessions within the current Region.

With the read consistency set to `GLOBAL`, a session in a secondary AWS Region sees changes made by that session. It also sees all committed changes from both the primary AWS Region and other secondary AWS Regions. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the secondary cluster is up-to-date with all committed data from the primary cluster, as of the time that the query began.

For more information about all the parameters involved with write forwarding, see [Configuration parameters for write forwarding \(p. 262\)](#).

Examples of using write forwarding

In the following example, the primary cluster is in the US East (N. Virginia) Region. The secondary cluster is in the US East (Ohio) Region. The example shows the effects of running `INSERT` statements followed by `SELECT` statements. Depending on the value of the `aurora_replica_read_consistency` setting, the results might differ depending on the timing of the statements. To achieve higher consistency, you might wait briefly before issuing the `SELECT` statement. Or Aurora can automatically wait until the results finish replicating before proceeding with `SELECT`.

In this example, there is a read consistency setting of `eventual`. Running an `INSERT` statement immediately followed by a `SELECT` statement still returns the value of `COUNT(*)`. This value reflects the number of rows before the new row is inserted. Running the `SELECT` again a short time later does return the updated row count. The `SELECT` statements don't do any waiting.

```
mysql> set aurora_replica_read_consistency = 'eventual';
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|      5   |
+-----+
1 row in set (0.00 sec)
mysql> insert into t1 values (6); select count(*) from t1;
+-----+
| count(*) |
+-----+
|      5   |
+-----+
1 row in set (0.00 sec)
```

```
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|      6 |
+-----+
1 row in set (0.00 sec)
```

With a read consistency setting of `session`, a `SELECT` statement immediately after an `INSERT` does wait until the changes from the `INSERT` statement are visible. Subsequent `SELECT` statements don't do any waiting.

```
mysql> set aurora_replica_read_consistency = 'session';
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|      6 |
+-----+
1 row in set (0.01 sec)
mysql> insert into t1 values (6); select count(*) from t1; select count(*) from t1;
Query OK, 1 row affected (0.08 sec)
+-----+
| count(*) |
+-----+
|      7 |
+-----+
1 row in set (0.37 sec)
+-----+
| count(*) |
+-----+
|      7 |
+-----+
1 row in set (0.00 sec)
```

With the read consistency setting still set to `session`, introducing a brief wait after performing an `INSERT` statement makes the updated row count available by the time the next `SELECT` statement runs.

```
mysql> insert into t1 values (6); select sleep(2); select count(*) from t1;
Query OK, 1 row affected (0.07 sec)
+-----+
| sleep(2) |
+-----+
|      0 |
+-----+
1 row in set (2.01 sec)
+-----+
| count(*) |
+-----+
|      8 |
+-----+
1 row in set (0.00 sec)
```

With a read consistency setting of `global`, each `SELECT` statement waits to ensure that all data changes as of the start time of the statement are visible before performing the query. The amount of waiting for each `SELECT` statement varies, depending on the amount of replication lag between the primary and secondary clusters.

```
mysql> set aurora_replica_read_consistency = 'global';
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
```

```
+-----+
|     8 |
+-----+
1 row in set (0.75 sec)
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|     8 |
+-----+
1 row in set (0.37 sec)
mysql> select count(*) from t1;
+-----+
| count(*) |
+-----+
|     8 |
+-----+
1 row in set (0.66 sec)
```

Running multipart statements with write forwarding

A DML statement might consist of multiple parts, such as a `INSERT ... SELECT` statement or a `DELETE ... WHERE` statement. In this case, the entire statement is forwarded to the primary cluster and run there.

Transactions with write forwarding

Whether the transaction is forwarded to the primary cluster depends on the access mode of the transaction. You can specify the access mode for the transaction by using the `SET TRANSACTION` statement or the `START TRANSACTION` statement. You can also specify the transaction access mode by changing the value of the Aurora MySQL session variable `tx_read_only`. You can only change this session value while you're connected to a secondary cluster that has write forwarding enabled.

If a long-running transaction doesn't issue any statement for a substantial period of time, it might exceed the idle timeout period. This period has a default of one minute. You can increase it up to one day. A transaction that exceeds the idle timeout is canceled by the primary cluster. The next subsequent statement you submit receives a timeout error. Then Aurora rolls back the transaction.

This type of error can occur in other cases when write forwarding becomes unavailable. For example, Aurora cancels any transactions that use write forwarding if you restart the primary cluster or if you turn off the write forwarding configuration setting.

Configuration parameters for write forwarding

The Aurora cluster parameter groups include settings for the write forwarding feature. Because these are cluster parameters, all DB instances in each cluster have the same values for these variables. Details about these parameters are summarized in the following table, with usage notes after the table.

Name	Scope	Type	Default value	Valid values
<code>aurora_fwd_master_idle_timeout</code> (Aurora MySQL version 2)	Global	unsigned integer	60	1–86,400
<code>aurora_fwd_master_max_connections</code> (Aurora MySQL version 2)	Global	unsigned long integer	10	0–90
<code>aurora_fwd_writer_idle_timeout</code> (Aurora MySQL version 3)	Global	unsigned integer	60	1–86,400

Name	Scope	Type	Default value	Valid values
aurora_fwd_writer_max_connections_global (Aurora MySQL version 3)	Global	unsigned long integer	10	0–90
aurora_replica_read_consistency	Session	Enum	"	EVENTUAL, SESSION, GLOBAL

To control incoming write requests from secondary clusters, use these settings on the primary cluster:

- `aurora_fwd_master_idle_timeout`, `aurora_fwd_writer_idle_timeout`: The number of seconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster before closing it. If the session remains idle beyond this period, Aurora cancels the session.
- `aurora_fwd_master_max_connections_pct`, `aurora_fwd_writer_max_connections_pct`: The upper limit on database connections that can be used on a writer DB instance to handle queries forwarded from readers. It's expressed as a percentage of the `max_connections` setting for the writer DB instance in the primary cluster. For example, if `max_connections` is 800 and `aurora_fwd_master_max_connections_pct` or `aurora_fwd_writer_max_connections_pct` is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the `max_connections` setting.

This setting applies only on the primary cluster, when one or more secondary clusters have write forwarding enabled. If you decrease the value, existing connections aren't affected. Aurora takes the new value of the setting into account when attempting to create a new connection from a secondary cluster. The default value is 10, representing 10% of the `max_connections` value. If you enable query forwarding on any of the secondary clusters, this setting must have a nonzero value for write operations from secondary clusters to succeed. If the value is zero, the write operations receive the error code `ER_CON_COUNT_ERROR` with the message `Not enough connections on writer to handle your request`.

The `aurora_replica_read_consistency` parameter is a session-level parameter that enables write forwarding. You use it in each session. You can specify `EVENTUAL`, `SESSION`, or `GLOBAL` for read consistency level. To learn more about consistency levels, see [Isolation and consistency for write forwarding \(p. 259\)](#). The following rules apply to this parameter:

- This is a session-level parameter. The default value is " (empty).
- Write forwarding is available in a session only if `aurora_replica_read_consistency` is set to `EVENTUAL` or `SESSION` or `GLOBAL`. This parameter is relevant only in reader instances of secondary clusters that have write forwarding enabled and that are in an Aurora global database.
- You can't set this variable (when empty) or unset (when already set) inside a multistatement transaction. However, you can change it from one valid value (`EVENTUAL`, `SESSION`, or `GLOBAL`) to another valid value (`EVENTUAL`, `SESSION`, or `GLOBAL`) during such a transaction.
- The variable can't be `SET` when write forwarding isn't enabled on the secondary cluster.
- Setting the session variable on a primary cluster doesn't have any effect. If you try to modify this variable on a primary cluster, you receive an error.

Amazon CloudWatch metrics for write forwarding

The following Amazon CloudWatch metrics apply to the primary cluster when you use write forwarding on one or more secondary clusters. These metrics are all measured on the writer DB instance in the primary cluster.

CloudWatch Metric (Aurora MySQL status variable)	Units and description
ForwardingMasterDMLLatency (-)	Milliseconds. Average time to process each forwarded DML statement on the writer DB instance. It doesn't include the time for the secondary cluster to forward the write request. It also doesn't include the time to replicate changes back to the secondary cluster. For Aurora MySQL version 2.
ForwardingMasterOpenSessions (Aurora_fwd_master_open_sessions)	Count. Number of forwarded sessions on the writer DB instance. For Aurora MySQL version 2.
ForwardingMasterDMLThroughput (-)	Count, per second. Number of forwarded DML statements processed each second by this writer DB instance. For Aurora MySQL version 2.
- (Aurora_fwd_master_dml_stmt_duration)	Microseconds. Total duration of DML statements forwarded to this writer DB instance. For Aurora MySQL version 2.
- (Aurora_fwd_master_dml_stmt_count)	Count. Total number of DML statements forwarded to this writer DB instance. For Aurora MySQL version 2.
- (Aurora_fwd_master_select_stmt_duration)	Microseconds. Total duration of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 2.
- (Aurora_fwd_master_select_stmt_count)	Count. Total number of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 2.
ForwardingWriterDMLLatency (-)	Milliseconds. Average time to process each forwarded DML statement on the writer DB instance. It doesn't include the time for the secondary cluster to forward the write request. It also doesn't include the time to replicate changes back to the secondary cluster. For Aurora MySQL version 3 and higher.
ForwardingWriterOpenSessions (Aurora_fwd_writer_open_sessions)	Count. Number of forwarded sessions on the writer DB instance. For Aurora MySQL version 3 and higher.
ForwardingWriterDMLThroughput (-)	Count, per second. Number of forwarded DML statements processed each second by this writer DB instance. For Aurora MySQL version 3 and higher.
- (Aurora_fwd_writer_dml_stmt_duration)	Microseconds. Total duration of DML statements forwarded to this writer DB instance.
- (Aurora_fwd_writer_dml_stmt_count)	Count. Total number of DML statements forwarded to this writer DB instance. For Aurora MySQL version 3 and higher.

CloudWatch Metric	Units and description
(Aurora MySQL status variable)	
– (Aurora_fwd_writer_select_stmt_duration)	Microseconds. Total duration of <code>SELECT</code> statements forwarded to this writer DB instance. For Aurora MySQL version 3 and higher.
– (Aurora_fwd_writer_select_stmt_count)	Count. Total number of <code>SELECT</code> statements forwarded to this writer DB instance. For Aurora MySQL version 3 and higher.

The following CloudWatch metrics apply to each secondary cluster. These metrics are measured on each reader DB instance in a secondary cluster with write forwarding enabled.

CloudWatch Metric	Unit and description
(Aurora MySQL status variable)	
ForwardingReplicaDMLLatency (–)	Milliseconds. Average response time in milliseconds of forwarded DMLs on replica.
ForwardingReplicaReadWaitLatency (–)	Milliseconds. Average wait time in milliseconds that a <code>SELECT</code> statement on a reader DB instance waits to catch up to the primary cluster. The degree to which the reader DB instance waits before processing a query depends on the <code>aurora_replica_read_consistency</code> setting.
ForwardingReplicaDMLThroughput (–)	Count (per second). Number of forwarded DML statements processed each second.
ForwardingReplicaReadWaitThroughput (–)	Count (<code>SELECT</code> statements per second). Total number of <code>SELECT</code> statements processed each second in all sessions that are forwarding writes.
ForwardingReplicaOpenSessions (Aurora_fwd_replica_open_sessions)	Count. The number of sessions that are using write forwarding on a reader DB instance.
ForwardingReplicaSelectLatency (–)	Milliseconds. Forwarded <code>SELECT</code> latency, average over all forwarded <code>SELECT</code> statements within the monitoring period.
ForwardingReplicaSelectThroughput (–)	Count per second. Forwarded <code>SELECT</code> throughput, per second average within the monitoring period.
– (Aurora_fwd_replica_dml_stmt_count)	Count. Total number of DML statements forwarded from this reader DB instance.
– (Aurora_fwd_replica_dml_stmt_duration)	Microseconds. Total duration of all DML statements forwarded from this reader DB instance.

CloudWatch Metric (Aurora MySQL status variable)	Unit and description
– (Aurora_fwd_replica_select_stmt_duration)	Microseconds. Total duration of SELECT statements forwarded from this reader DB instance.
– (Aurora_fwd_replica_select_stmt_count)	Count. Total number of SELECT statements forwarded from this reader DB instance.
– (Aurora_fwd_replica_read_wait_duration)	Microseconds. Total duration of waits due to the read consistency setting on this reader DB instance.
– (Aurora_fwd_replica_read_wait_count)	Count. Total number of read-after-write waits on this reader DB instance.
– (Aurora_fwd_replica_errors_session_limit)	Count. Number of sessions rejected by the primary cluster due to the error conditions writer full or Too many forwarded statements in progress.

Using failover in an Amazon Aurora global database

An Aurora global database provides more comprehensive failover capabilities than the [failover provided by a default Aurora DB cluster \(p. 68\)](#). By using an Aurora global database, you can plan for and recover from disaster fairly quickly. Recovery from disaster is typically measured using values for RTO and RPO.

- **Recovery time objective (RTO)** – The time it takes a system to return to a working state after a disaster. In other words, RTO measures downtime. For an Aurora global database, RTO can be in the order of minutes.
- **Recovery point objective (RPO)** – The amount of data that can be lost (measured in time). For an Aurora global database, RPO is typically measured in seconds. With an Aurora PostgreSQL-based global database, you can use the `rds.global_db_rpo` parameter to set and track the upper bound on RPO, but doing so might affect transaction processing on the primary cluster's writer node. For more information, see [Managing RPOs for Aurora PostgreSQL-based global databases \(p. 272\)](#).

With an Aurora global database, there are two different approaches to failover depending on the scenario.

- **Manual unplanned failover ("detach and promote")** – To recover from an unplanned outage or to do disaster recovery (DR) testing, perform a cross-Region failover to one of the secondaries in your Aurora global database. The RTO for this manual process depends on how quickly you can perform the tasks listed in [Recovering an Amazon Aurora global database from an unplanned outage \(p. 267\)](#). The RPO is typically measured in seconds, but this depends on the Aurora storage replication lag across the network at the time of the failure.
- **Managed planned failover** – This feature is intended for controlled environments, such as operational maintenance and other planned operational procedures. By using managed planned failover, you can relocate the primary DB cluster of your Aurora global database to one of the secondary Regions. Because this feature synchronizes secondary DB clusters with the primary before making any other changes, RPO is 0 (no data loss). To learn more, see [Performing managed planned failovers for Amazon Aurora global databases \(p. 268\)](#).

Topics

- [Recovering an Amazon Aurora global database from an unplanned outage \(p. 267\)](#)
- [Performing managed planned failovers for Amazon Aurora global databases \(p. 268\)](#)
- [Managing RPOs for Aurora PostgreSQL-based global databases \(p. 272\)](#)

Recovering an Amazon Aurora global database from an unplanned outage

On very rare occasions, your Aurora global database might experience an unexpected outage in its primary AWS Region. If this happens, your primary Aurora DB cluster and its writer node aren't available, and the replication between the primary cluster and the secondaries ceases. To minimize both downtime (RTO) and data loss (RPO), you can work quickly to perform a cross-Region failover and reconstruct your Aurora global database.

Tip

We recommend that you understand this process before using it. Have a plan ready to quickly proceed at the first sign of a Region-wide issue. Be ready to identify the secondary Region with the least lag time. Use Amazon CloudWatch regularly to track lag times for the secondary clusters. Make sure to test your plan to check that your procedures are complete and accurate, and that staff are trained to perform a DR failover before it really happens.

To fail over to a secondary cluster after an unplanned outage in the primary Region

1. Stop issuing DML statements and other write operations to the primary Aurora DB cluster in the AWS Region with the outage.
2. Identify an Aurora DB cluster from a secondary AWS Region to use as a new primary DB cluster. If you have two or more secondary AWS Regions in your Aurora global database, choose the secondary cluster that has the least lag time.
3. Detach your chosen secondary DB cluster from the Aurora global database.

Removing a secondary DB cluster from an Aurora global database immediately stops the replication from the primary to this secondary and promotes it to a standalone provisioned Aurora DB cluster with full read/write capabilities. Any other secondary Aurora DB clusters associated with the primary cluster in the Region with the outage are still available and can accept calls from your application. They also consume resources. Because you're recreating the Aurora global database, remove the other secondary DB clusters before creating the new Aurora global database in the following steps. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (*split-brain* issues).

For detailed steps for detaching, see [Removing a cluster from an Amazon Aurora global database \(p. 251\)](#).

4. Reconfigure your application to send all write operations to this now standalone Aurora DB cluster using its new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the `-ro` from the cluster's endpoint string in your application.

For example, the secondary cluster's endpoint `my-global.cluster-ro-aaaaaabbbbb.us-west-1.rds.amazonaws.com` becomes `my-global.cluster-aaaaaabbbbb.us-west-1.rds.amazonaws.com` when that cluster is detached from the Aurora global database.

This Aurora DB cluster becomes the primary cluster of a new Aurora global database when you start adding Regions to it in the next step.

5. Add an AWS Region to the DB cluster. When you do this, the replication process from primary to secondary begins. For detailed steps to add a Region, see [Adding an AWS Region to an Amazon Aurora global database \(p. 242\)](#).

6. Add more AWS Regions as needed to recreate the topology needed to support your application.

Make sure that application writes are sent to the correct Aurora DB cluster before, during, and after making these changes. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (*split-brain* issues).

If you reconfigured in response to an outage in an AWS Region, you might be able to return your Aurora global database to its original primary AWS Region after the outage is resolved. In this case, you use the managed planned failover process. Your Aurora global database must use a version of Aurora PostgreSQL or Aurora MySQL that supports managed planned failovers. For more information, see [Performing managed planned failovers for Amazon Aurora global databases \(p. 268\)](#).

Performing managed planned failovers for Amazon Aurora global databases

By using managed planned failovers, you can relocate the primary cluster of your Aurora global database to a different AWS Region on a routine basis. This approach is intended for controlled environments, such as operational maintenance and other planned operational procedures.

As an example, say a financial institution headquartered in New York has branch offices located in San Francisco, the UK, and Europe. The organization's core business applications use an Aurora global database. Its primary cluster runs in the US East (Ohio) Region. It has secondary clusters running in the US West (N. California) Region, Europe (London) Region, and the Europe (Frankfurt) Region. Every quarter, it relocates the primary cluster from the (current) primary AWS Region to the secondary Region designated for that rotation.

Note

Managed *planned* failover is designed to be used on a healthy Aurora global database. To recover from an unplanned outage or to do disaster recovery (DR) testing, follow the "detach and promote" process detailed in [Recovering an Amazon Aurora global database from an unplanned outage \(p. 267\)](#).

During a managed planned failover, your primary cluster is failed over to your choice of secondary Region while your Aurora global database's existing replication topology is maintained. Before the managed planned failover process begins, Aurora global database synchronizes all secondary clusters with its primary cluster. After ensuring that all clusters are synchronized, the managed planned failover begins. The DB cluster in the primary Region becomes read-only. The chosen secondary cluster promotes one of its read-only nodes to full writer status, thus allowing the cluster to assume the role of primary cluster. Because all secondary clusters were synchronized with the primary at the beginning of the process, the new primary continues operations for the Aurora global database without losing any data. Your database is unavailable for a short time while the primary and selected secondary clusters are assuming their new roles.

To optimize application availability, we recommend that you do the following before using this feature:

- Perform this operation during nonpeak hours or at another time when writes to the primary DB cluster are minimal.
- Take applications offline to prevent writes from being sent to the primary cluster of Aurora global database.
- Check lag times for all secondary Aurora DB clusters in the Aurora global database. Choose the secondary with the least overall lag time for the managed planned failover. Use Amazon CloudWatch to view the `AuroraGlobalDBReplicationLag` metric for all secondaries. This metric tells you how far behind (in milliseconds) a secondary is to the primary DB cluster. Its value is directly proportional to the time it'll take for Aurora to complete failover. In other words, the larger the lag value, the longer the outage, so choose the Region with the least lag.

For more information about CloudWatch metrics for Aurora, see [Cluster-level metrics for Amazon Aurora \(p. 633\)](#).

During a managed planned failover, the chosen secondary DB cluster is promoted to its new role as primary. However, it doesn't inherit the various configuration options of the primary DB cluster. A mismatch in configuration can lead to performance issues, workload incompatibilities, and other anomalous behavior. To avoid such issues, we recommend that you resolve differences between your Aurora global database clusters for the following:

- **Configure Aurora DB cluster parameter group for the new primary, if necessary** – You can configure your Aurora DB cluster parameter groups independently for each Aurora cluster in your Aurora global database. That means that when you promote a secondary DB cluster to take over the primary role, the parameter group from the secondary might be configured differently than for the primary. If so, modify the promoted secondary DB cluster's parameter group to conform to your primary cluster's settings. To learn how, see [Modifying parameters for an Aurora global database \(p. 250\)](#).
- **Configure monitoring tools and options, such as Amazon CloudWatch Events and alarms** – Configure the promoted DB cluster with the same logging ability, alarms, and so on as needed for the global database. As with parameter groups, configuration for these features isn't inherited from the primary during the failover process. For more information about Aurora DB clusters and monitoring, see [Overview of monitoring Amazon Aurora](#).
- **Configure integrations with other AWS services** – If your Aurora global database integrates with AWS services, such as AWS Secrets Manager, AWS Identity and Access Management, Amazon S3, and AWS Lambda, you need to make sure these are configured as needed. For more information about integrating Aurora global databases with IAM, Amazon S3 and Lambda, see [Using Amazon Aurora global databases with other AWS services \(p. 279\)](#). To learn more about Secrets Manager, see [How to automate replication of secrets in AWS Secrets Manager across AWS Regions](#).

When the failover process completes, the promoted Aurora DB cluster can handle write operations for the Aurora global database. Make sure to change the endpoint for your application to use the new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the `-ro` from the promoted cluster's endpoint string in your application.

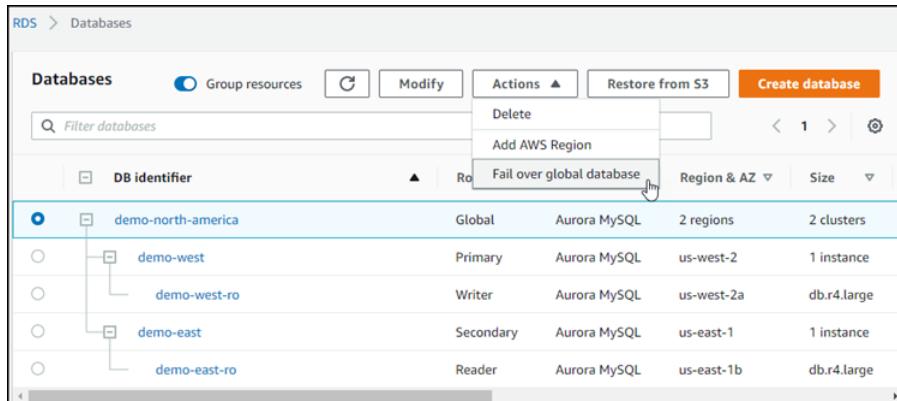

For example, the secondary cluster's endpoint `my-global.cluster-ro-aaaaaabbbbb.us-west-1.rds.amazonaws.com` becomes `my-global.cluster-aaaaaabbbbb.us-west-1.rds.amazonaws.com` when that cluster is promoted to primary.

You can fail over your Aurora global database using the AWS Management Console, the AWS CLI, or the RDS API.

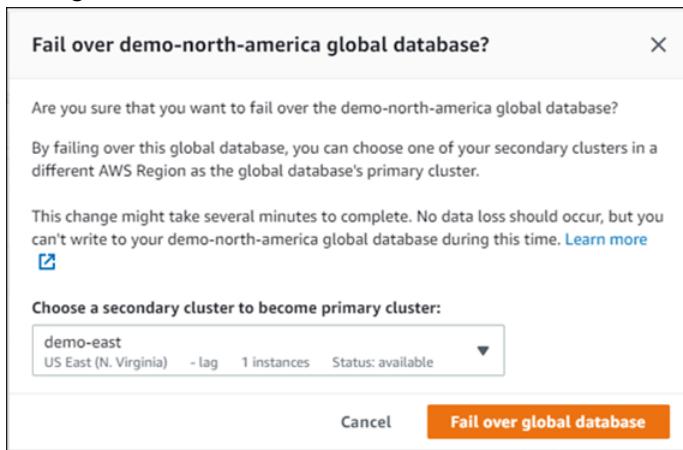

Console

To start the failover process on your Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases** and find the Aurora global database you want to fail over.
3. Choose **Fail over global database** from Actions menu. The failover process doesn't begin until after you choose the failover target in the next step. At this point, the failover is pending.

- Choose the secondary Aurora DB cluster that you want to promote to primary. The secondary DB cluster must be **available**. If you have more than one secondary DB cluster, you can compare the **lag** amount for all secondaries and choose the one with the smallest amount of lag.

- Choose **Fail over global database** to confirm your choice of secondary DB cluster and begin the failover process.

Tip

The failover process can take some time to complete. You can cancel once the process is underway, but it can take some time to return your Aurora global database to its original configuration.

DB identifier	Role	Engine	Region & AZ	Size
demo-north-america	Global	Aurora MySQL	2 regions	2 clusters
demo-west	Pending	Aurora MySQL	us-west-2	1 instance
demo-west-ro	Writer	Aurora MySQL	us-west-2a	db.r4.large
demo-east	Pending	Aurora MySQL	us-east-1	1 instance
demo-east-ro	Reader	Aurora MySQL	us-east-1b	db.r4.large

The **Status** column of the Databases list shows the state of each Aurora DB instance and Aurora DB cluster during the failover process.

DB identifier	Role	Engine	Region & AZ	Size	Status
demo-north-america	Global	Aurora MySQL	2 regions	2 clusters	Failing-over
demo-east	Pending	Aurora MySQL	us-east-1	1 instance	Modifying
demo-east-ro	Reader	Aurora MySQL	us-east-1b	db.r4.large	Modifying
demo-west	Pending	Aurora MySQL	us-west-2	1 instance	Modifying
demo-west-ro	Writer	Aurora MySQL	us-west-2a	db.r4.large	Modifying

The status bar at the top of the Console displays progress and provides a **Cancel failover** option. If you choose **Cancel failover**, you're given the option to proceed with the failover or to cancel the failover process.

Are you sure that you want to cancel the failover of the global database lab-operations?

If you do, these actions occur:

- The lab-test-operations cluster reverts to the primary cluster.
- The lab-operations-cluster-1 cluster reverts to a secondary cluster.

Close **Cancel failover**

Choose **Cancel failover** if you want to cancel the failover.

- Choose **Close** to continue failing over and dismiss the prompt.

When the failover completes, you can see the Aurora DB clusters and their current state in the **Databases** list, as shown following.

Databases					
	DB Identifier	Role	Engine	Region & AZ	Size
...	demo-north-america	Global	Aurora MySQL	2 regions	2 clusters
...	demo-east	Primary	Aurora MySQL	us-east-1	1 instance
...	demo-east-ro	Writer	Aurora MySQL	us-east-1b	db.r4.large
...	demo-west	Secondary	Aurora MySQL	us-west-2	1 instance
...	demo-west-ro	Reader	Aurora MySQL	us-west-2a	db.r4.large

AWS CLI

To fail over an Aurora global database

Use the [failover-global-cluster](#) CLI command to fail over your Aurora global database. With the command, pass values for the following parameters.

- **--region** – Specify the AWS Region where the primary DB cluster of the Aurora global database is running.
- **--global-cluster-identifier** – Specify the name of your Aurora global database.
- **--target-db-cluster-identifier** – Specify the Amazon Resource Name (ARN) of the Aurora DB cluster that you want to promote to be the primary for the Aurora global database.

For Linux, macOS, or Unix:

```
aws rds --region aws-Region \
    failover-global-cluster --global-cluster-identifier global_database_id \
    --target-db-cluster-identifier ARN-of-secondary-to-promote
```

For Windows:

```
aws rds --region aws-Region ^
    failover-global-cluster --global-cluster-identifier global_database_id ^
    --target-db-cluster-identifier ARN-of-secondary-to-promote
```

RDS API

To fail over an Aurora global database, run the [FailoverGlobalCluster](#) API operation.

Managing RPOs for Aurora PostgreSQL-based global databases

With an Aurora PostgreSQL-based global database, you can manage the recovery point objective (RPO) for your Aurora global database by using PostgreSQL's `rds.global_db_rpo` parameter. RPO represents maximum amount of data that can be lost in the event of an outage.

When you set an RPO for your Aurora PostgreSQL-based global database, Aurora monitors the *RPO lag time* of all secondary clusters to make sure that at least one secondary cluster stays within the target RPO window. RPO lag time is another time-based metric.

The RPO is used when your database resumes operations in a new AWS Region after a failover. Aurora evaluates RPO and RPO lag times to commit (or block) transactions on the primary as follows:

- Commits the transaction if at least one secondary DB cluster has an RPO lag time less than the RPO.

- Blocks the transaction if all secondary DB clusters have RPO lag times that are larger than the RPO. It also logs the event to the PostgreSQL log file and emits "wait" events that show the blocked sessions.

In other words, if all secondary clusters are behind the target RPO, Aurora pauses transactions on the primary cluster until at least one of the secondary clusters catches up. Paused transactions are resumed and committed as soon as the lag time of at least one secondary DB cluster becomes less than the RPO. The result is that no transactions can commit until the RPO is met.

If you set this parameter as outlined in the following, you can then also monitor the metrics that it generates. You can do so by using `psql` or another tool to query the Aurora global database's primary DB cluster and obtain detailed information about your Aurora PostgreSQL-based global database's operations. To learn how, see [Monitoring Aurora PostgreSQL-based Aurora global databases \(p. 277\)](#).

Topics

- [Setting the recovery point objective \(p. 273\)](#)
- [Viewing the recovery point objective \(p. 274\)](#)
- [Disabling the recovery point objective \(p. 275\)](#)

Setting the recovery point objective

The `rds.global_db_rpo` parameter controls the RPO setting for a PostgreSQL database. This parameter is supported by Aurora PostgreSQL. Valid values for `rds.global_db_rpo` range from 20 seconds to 2,147,483,647 seconds (68 years). Choose a realistic value to meet your business need and use case. For example, you might want to allow up to 10 minutes for your RPO, in which case you set the value to 600.

You can set this value for your Aurora PostgreSQL-based global database by using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To set the RPO

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the primary cluster of your Aurora global database and open the **Configuration** tab to find its DB cluster parameter group. For example, the default parameter group for a primary DB cluster running Aurora PostgreSQL 11.7 is `default.aurora-postgresql11`.

Parameter groups can't be edited directly. Instead, you do the following:

- Create a custom DB cluster parameter group using the appropriate default parameter group as the starting point. For example, create a custom DB cluster parameter group based on the `default.aurora-postgresql11`.
- On your custom DB parameter group, set the value of the `rds.global_db_rpo` parameter to meet your use case. Valid values range from 20 seconds up to the maximum integer value of 2,147,483,647 (68 years).
- Apply the modified DB cluster parameter group to your Aurora DB cluster.

For more information, see [Modifying parameters in a DB cluster parameter group \(p. 349\)](#).

AWS CLI

To set the `rds.global_db_rpo` parameter, use the `modify-db-cluster-parameter-group` CLI command. In the command, specify the name of your primary cluster's parameter group and values for RPO parameter.

The following example sets the RPO to 600 seconds (10 minutes) for the primary DB cluster's parameter group named `my_custom_global_parameter_group`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
--db-cluster-parameter-group-name my_custom_global_parameter_group \
--parameters "ParameterName=rds.global_db_rpo,ParameterValue=600,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
--db-cluster-parameter-group-name my_custom_global_parameter_group ^
--parameters "ParameterName=rds.global_db_rpo,ParameterValue=600,ApplyMethod=immediate"
```

RDS API

To modify the `rds.global_db_rpo` parameter, use the Amazon RDS [ModifyDBClusterParameterGroup](#) API operation.

Viewing the recovery point objective

The recovery point objective (RPO) of a global database is stored in the `rds.global_db_rpo` parameter for each DB cluster. You can connect to the endpoint for the secondary cluster you want to view and use `psql` to query the instance for this value.

```
db-name=>show rds.global_db_rpo;
```

If this parameter isn't set, the query returns the following:

```
rds.global_db_rpo
-----
-1
(1 row)
```

This next response is from a secondary DB cluster that has 1 minute RPO setting.

```
rds.global_db_rpo
-----
60
(1 row)
```

You can also use the CLI to get values for find out if `rds.global_db_rpo` is active on any of the Aurora DB clusters by using the CLI to get values of all user parameters for the cluster.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameters \
--db-cluster-parameter-group-name lab-test-apg-global \
--source user
```

For Windows:

```
aws rds describe-db-cluster-parameters ^
--db-cluster-parameter-group-name lab-test-apg-global *
```

```
--source user
```

The command returns output similar to the following for all `user` parameters that aren't default-engine or system DB cluster parameters.

```
{  
    "Parameters": [  
        {  
            "ParameterName": "rds.global_db_rpo",  
            "ParameterValue": "60",  
            "Description": "(s) Recovery point objective threshold, in seconds, that blocks user commits when it is violated.",  
            "Source": "user",  
            "ApplyType": "dynamic",  
            "DataType": "integer",  
            "AllowedValues": "20-2147483647",  
            "IsModifiable": true,  
            "ApplyMethod": "immediate",  
            "SupportedEngineModes": [  
                "provisioned"  
            ]  
        }  
    ]  
}
```

To learn more about viewing parameters of the cluster parameter group, see [Viewing parameter values for a DB cluster parameter group \(p. 360\)](#).

Disabling the recovery point objective

To disable the RPO, reset the `rds.global_db_rpo` parameter. You can reset parameters using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To disable the RPO

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose your primary DB cluster parameter group.
4. Choose **Edit parameters**.
5. Choose the box next to the `rds.global_db_rpo` parameter.
6. Choose **Reset**.
7. When the screen shows **Reset parameters in DB parameter group**, choose **Reset parameters**.

For more information on how to reset a parameter with the console, see [Modifying parameters in a DB cluster parameter group \(p. 349\)](#).

AWS CLI

To reset the `rds.global_db_rpo` parameter, use the `reset-db-cluster-parameter-group` command.

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group \  
  --db-cluster-parameter-group-name global_db_cluster_parameter_group \  
  \
```

```
--parameters "ParameterName=rds.global_db_rpo,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
--db-cluster-parameter-group-name global_db_cluster_parameter_group ^
--parameters "ParameterName=rds.global_db_rpo,ApplyMethod=immediate"
```

RDS API

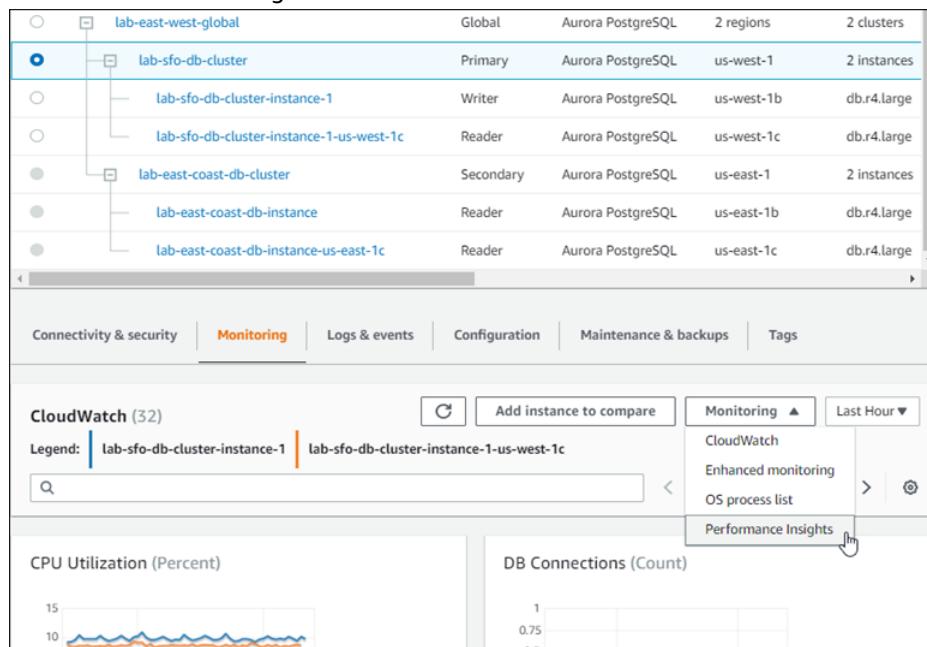

To reset the `rds.global_db_rpo` parameter, use the Amazon RDS API [ResetDBClusterParameterGroup](#) operation.

Monitoring an Amazon Aurora global database

When you create the Aurora DB clusters that make up your Aurora global database, you can choose many options that let you monitor your DB cluster's performance. These options include the following:

- Amazon RDS Performance Insights – Enables performance schema in the underlying Aurora database engine. To learn more about Performance Insights and Aurora global databases, see [Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights \(p. 277\)](#).
- Enhanced monitoring – Generates metrics for process or thread utilization on the CPU.
- Amazon CloudWatch Logs – Publishes specified log types to CloudWatch Logs. Error logs are published by default, but you can choose other logs specific to your Aurora database engine.
 - For Aurora MySQL-based Aurora DB clusters, you can export the audit log, general log, and slow query log.
 - For Aurora PostgreSQL-based Aurora DB clusters, you can export the Postgresql log.
- For Aurora PostgreSQL-based global databases, you can use certain functions to check status of your Aurora global database and its instances. To learn how, see [Monitoring Aurora PostgreSQL-based Aurora global databases \(p. 277\)](#).

The following screenshot shows some of the options available on the Monitoring tab of a primary Aurora DB cluster in an Aurora global database.

For more information, see [Monitoring metrics in an Amazon Aurora cluster \(p. 541\)](#).

Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights

You can use Amazon RDS Performance Insights for your Aurora global databases. You enable this feature individually, for each Aurora DB cluster in your Aurora global database. To do so, you choose **Enable Performance Insights** in the **Additional configuration** section of the Create database page. Or you can modify your Aurora DB clusters to use this feature after they are up and running. You can enable or turn off Performance Insights for each cluster that's part of your Aurora global database.

The reports created by Performance Insights apply to each cluster in the global database. When you add a new secondary AWS Region to an Aurora global database that's already using Performance Insights, be sure that you enable Performance Insights in the newly added cluster. It doesn't inherit the Performance Insights setting from the existing global database.

You can switch AWS Regions while viewing the Performance Insights page for a DB instance that's attached to a global database. However, you might not see performance information immediately after switching AWS Regions. Although the DB instances might have identical names in each AWS Region, the associated Performance Insights URL is different for each DB instance. After switching AWS Regions, choose the name of the DB instance again in the Performance Insights navigation pane.

For DB instances associated with a global database, the factors affecting performance might be different in each AWS Region. For example, the DB instances in each AWS Region might have different capacity.

To learn more about using Performance Insights, see [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 573\)](#).

Monitoring Aurora PostgreSQL-based Aurora global databases

To view the status of a global database, use the `aurora_global_db_status` and `aurora_global_db_instance_status` functions.

Note

Only Aurora PostgreSQL supports the `aurora_global_db_status` and `aurora_global_db_instance_status` functions.

To monitor an Aurora PostgreSQL-based global database

1. Connect to the global database primary cluster endpoint using a PostgreSQL utility such as `psql`. For more information about how to connect, see [Connecting to an Amazon Aurora global database \(p. 254\)](#).
2. Use the `aurora_global_db_status` function in a `psql` command to list the primary and secondary volumes. This shows the lag times of the global database secondary DB clusters.

```
postgres=> select * from aurora_global_db_status();
```

aws_region	highest_lsn_written	durability_lag_in_msec	rpo_lag_in_msec	last_lag_calculation_time	feedback_epoch	feedback_xmin
us-east-1	93763984222	-1	-1	1970-01-01 00:00:00+00	0	0
us-west-2	93763984222	900	1090	2020-05-12 22:49:14.328+00	2	3315479243

(2 rows)

The output includes a row for each DB cluster of the global database containing the following columns:

- **aws_region** – The AWS Region that this DB cluster is in. For tables listing AWS Regions by engine, see [Regions and Availability Zones](#).
- **highest_lsn_written** – The highest log sequence number (LSN) currently written on this DB cluster.

A *log sequence number (LSN)* is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.

- **durability_lag_in_msec** – The timestamp difference between the highest log sequence number written on a secondary DB cluster (**highest_lsn_written**) and the **highest_lsn_written** on the primary DB cluster.
- **rpo_lag_in_msec** – The recovery point objective (RPO) lag. This lag is the time difference between the most recent user transaction commit stored on a secondary DB cluster and the most recent user transaction commit stored on the primary DB cluster.
- **last_lag_calculation_time** – The timestamp when values were last calculated for **durability_lag_in_msec** and **rpo_lag_in_msec**.
- **feedback_epoch** – The epoch the secondary DB cluster uses when it generates hot standby information.

Hot standby is when a DB cluster can connect and query while the server is in recovery or standby mode. Hot standby feedback is information about the DB cluster when it's in hot standby. For more information, see [Hot standby](#) in the PostgreSQL documentation.

- **feedback_xmin** – The minimum (oldest) active transaction ID used by the secondary DB cluster.

3. Use the `aurora_global_db_instance_status` function to list all secondary DB instances for both the primary DB cluster and secondary DB clusters.

```
postgres=> select * from aurora_global_db_instance_status();
```

server_id	aws_region	durable_lsn	highest_lsn_rcvd	feedback_epoch	feedback_xmin	oldest_read_view_lsn	visibility_lag_in_msec	session_id
apg-global-db-rpo-mammothrw-elephantro-1-n1	us-east-1	93763985102						MASTER_SESSION_ID
apg-global-db-rpo-mammothrw-elephantro-1-n2	us-east-1	93763985099	93763985102		2		10	f38430cf-6576-479a-b296-dc06b1b1964a
apg-global-db-rpo-elephantro-mammothrw-n1	us-west-2	93763985095	93763985099		2		1017	0d9f1d98-04ad-4aa4-8fdd-e08674cbbbfe
								3315479243

(3 rows)

The output includes a row for each DB instance of the global database containing the following columns:

- **server_id** – The server identifier for the DB instance.
- **session_id** – A unique identifier for the current session.
- **aws_region** – The AWS Region that this DB instance is in. For tables listing AWS Regions by engine, see [Regions and Availability Zones](#).
- **durable_lsn** – The LSN made durable in storage.

- **highest_lsn_rcvd** – The highest LSN received by the DB Instance from the writer DB Instance.
- **feedback_epoch** – The epoch the DB instance uses when it generates hot standby information.

Hot standby is when a DB instance can connect and query while the server is in recovery or standby mode. Hot standby feedback is information about the DB instance when it's in hot standby. For more information, see the PostgreSQL documentation on [Hot standby](#).

- **feedback_xmin** – The minimum (oldest) active transaction ID used by the DB instance.
- **oldest_read_view_lsn** – The oldest LSN used by the DB instance to read from storage.
- **visibility_lag_in_msec** – How far this DB instance is lagging behind the writer DB instance.

To see how these values change over time, consider the following transaction block where a table insert takes an hour.

```
psql> BEGIN;
psql> INSERT INTO table1 SELECT Large_Data_That_Takes_1_Hr_To_Insert;
psql> COMMIT;
```

In some cases, there might be a network disconnect between the primary DB cluster and the secondary DB cluster after the `BEGIN` statement. If so, the secondary DB cluster's `replication_lag_in_msec` value starts increasing. At the end of the `INSERT` statement, the `replication_lag_in_msec` value is 1 hour. However, the `rpo_lag_in_msec` value is 0 because all the user data committed between the primary DB cluster and secondary DB cluster are still the same. As soon as the `COMMIT` statement completes, the `rpo_lag_in_msec` value increases.

Using Amazon Aurora global databases with other AWS services

You can use your Aurora global databases with other AWS services, such as Amazon S3 and AWS Lambda. Doing so requires that all Aurora DB clusters in your global database have the same privileges, external functions, and so on in the respective AWS Regions. Because a read-only Aurora secondary DB cluster in an Aurora global database can be promoted to the role of primary, we recommend that you set up write privileges ahead of time, on all Aurora DB clusters for any services you plan to use with your Aurora global database.

The following procedures summarize the actions to take for each AWS service.

To invoke AWS Lambda functions from an Aurora global database

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster \(p. 1010\)](#).
2. For each cluster in the Aurora global database, set the (ARN) of the new IAM (IAM) role.
3. To permit database users in an Aurora global database to invoke Lambda functions, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 991\)](#) with each cluster in the Aurora global database.
4. Configure each cluster in the Aurora global database to allow outbound connections to Lambda. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services \(p. 996\)](#).

To load data from Amazon S3

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket \(p. 997\)](#).

2. For each Aurora cluster in the global database, set either the `aurora_load_from_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_load_from_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.
3. To permit database users in an Aurora global database to access S3, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 991\)](#) with each Aurora cluster in the global database.
4. Configure each Aurora cluster in the global database to allow outbound connections to S3. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services \(p. 996\)](#).

To save queried data to Amazon S3

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket \(p. 1004\)](#).
2. For each Aurora cluster in the global database, set either the `aurora_select_into_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_select_into_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.
3. To permit database users in an Aurora global database to access S3, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 991\)](#) with each Aurora cluster in the global database.
4. Configure each Aurora cluster in the global database to allow outbound connections to S3. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services \(p. 996\)](#).

Upgrading an Amazon Aurora global database

Upgrading an Aurora global database follows the same procedures as upgrading Aurora DB clusters. However, following are some important differences to take note of before you start the process.

Major version upgrades

When you perform a major version upgrade of an Amazon Aurora global database, you upgrade the global database cluster instead the individual clusters that it contains.

To learn how to upgrade an Aurora PostgreSQL global database to a higher major version, see [In-place major upgrades for global databases \(p. 1687\)](#). To learn how to upgrade an Aurora MySQL global database to a higher major version, see [In-place major upgrades for global databases \(p. 1101\)](#).

Note

With an Aurora global database based on Aurora PostgreSQL, you can't perform a major version upgrade of the Aurora DB engine if the recovery point objective (RPO) feature is turned on.

Minor version upgrades

For a minor upgrade on an Aurora global database, you upgrade all of the secondary clusters before you upgrade the primary cluster.

To learn how to upgrade an Aurora PostgreSQL global database to a higher minor version, see [Manually upgrading the Aurora PostgreSQL engine \(p. 1686\)](#). To learn how to upgrade an Aurora MySQL global database to a higher minor version, see [Upgrading Aurora MySQL by modifying the engine version \(p. 1088\)](#).

Connecting to an Amazon Aurora DB cluster

You can connect to an Aurora DB cluster using the same tools that you use to connect to a MySQL or PostgreSQL database. You specify a connection string with any script, utility, or application that connects to a MySQL or PostgreSQL DB instance. You use the same public key for Secure Sockets Layer (SSL) connections.

In the connection string, you typically use the host and port information from special endpoints associated with the DB cluster. With these endpoints, you can use the same connection parameters regardless of how many DB instances are in the cluster. You also use the host and port information from a specific DB instance in your Aurora DB cluster for specialized tasks, such as troubleshooting.

Note

For Aurora Serverless v1 DB clusters, you connect to the database endpoint rather than to the DB instance. You can find the database endpoint for an Aurora Serverless v1 DB cluster on the **Connectivity & security** tab of the AWS Management Console. For more information, see [Using Amazon Aurora Serverless v1 \(p. 147\)](#).

Regardless of the Aurora DB engine and specific tools you use to work with the DB cluster or instance, the endpoint must be accessible. An Amazon Aurora DB cluster can be created only in a virtual private cloud (VPC) based on the Amazon VPC service. That means that you access the endpoint from either inside the VPC or outside the VPC using one of the following approaches.

- **Access the Amazon Aurora DB cluster inside the VPC** – Enable access to the Amazon Aurora DB cluster through the VPC. You do so by editing the Inbound rules on the Security group for the VPC to allow access to your specific Aurora DB cluster. To learn more, including how to configure your VPC for different Aurora DB cluster scenarios, see [Amazon Virtual Private Cloud VPCs and Amazon Aurora](#).
- **Access the Amazon Aurora DB cluster outside the VPC** – To access an Amazon Aurora DB cluster from outside the VPC, use the public endpoint address of the Amazon Aurora DB cluster. You can also connect to an Amazon Aurora DB cluster that's inside a VPC from an Amazon EC2 instance that's not in the VPC by using ClassicLink. For more information, see [A DB instance in a VPC accessed by an EC2 instance not in a VPC \(p. 1803\)](#).

For more information, see [Troubleshooting Aurora connection failures \(p. 287\)](#).

Topics

- [Connecting to an Amazon Aurora MySQL DB cluster \(p. 281\)](#)
- [Connecting to an Amazon Aurora PostgreSQL DB cluster \(p. 285\)](#)
- [Troubleshooting Aurora connection failures \(p. 287\)](#)

Connecting to an Amazon Aurora MySQL DB cluster

To authenticate to your Aurora MySQL DB cluster, you can use either MySQL user name and password authentication or AWS Identity and Access Management (IAM) database authentication. For more information on using MySQL user name and password authentication, see [Access control and account management](#) in the MySQL documentation. For more information on using IAM database authentication, see [IAM database authentication \(p. 1743\)](#).

When you have a connection to your Amazon Aurora DB cluster with MySQL 8.0 compatibility, you can run SQL commands that are compatible with MySQL version 8.0. The minimum compatible version is MySQL 8.0.23. For more information about MySQL 8.0 SQL syntax, see the [MySQL 8.0 reference manual](#). For information about limitations that apply to Aurora MySQL version 3, see [Comparison of Aurora MySQL version 3 and community MySQL 8.0 \(p. 756\)](#).

When you have a connection to your Amazon Aurora DB cluster with MySQL 5.7 compatibility, you can run SQL commands that are compatible with MySQL version 5.7. For more information about MySQL 5.7 SQL syntax, see the [MySQL 5.7 reference manual](#). For information about limitations that apply to Aurora MySQL 5.7, see [Aurora MySQL version 2 compatible with MySQL 5.7 \(p. 773\)](#).

When you have a connection to your Amazon Aurora DB cluster with MySQL 5.6 compatibility, you can run SQL commands that are compatible with MySQL version 5.6. For more information about MySQL 5.6 SQL syntax, see the [MySQL 5.6 reference manual](#).

Note

For a helpful and detailed guide on connecting to an Amazon Aurora MySQL DB cluster, you can see the [Aurora connection management](#) handbook.

In the details view for your DB cluster, you can find the cluster endpoint, which you can use in your MySQL connection string. The endpoint is made up of the domain name and port for your DB cluster. For example, if an endpoint value is `mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com:3306`, then you specify the following values in a MySQL connection string:

- For host or host name, specify `mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com`
- For port, specify 3306 or the port value you used when you created the DB cluster

The cluster endpoint connects you to the primary instance for the DB cluster. You can perform both read and write operations using the cluster endpoint. Your DB cluster can also have up to 15 Aurora Replicas that support read-only access to the data in your DB cluster. The primary instance and each Aurora Replica has a unique endpoint that is independent of the cluster endpoint and allows you to connect to a specific DB instance in the cluster directly. The cluster endpoint always points to the primary instance. If the primary instance fails and is replaced, then the cluster endpoint points to the new primary instance.

To view the cluster endpoint (writer endpoint), choose **Databases** on the Amazon RDS console and choose the name of the DB cluster to show the DB cluster details.

The screenshot shows the AWS RDS console for an Aurora MySQL cluster named "aurora-cl-mysql". The cluster has three instances: dbinstance4 (Writer), dbinstance1 (Reader), and dbinstance2 (Reader). The "Connectivity & security" tab is selected, showing two endpoints: "aurora-cl-mysql.cluster-ro" (Available, Reader) and "aurora-cl-mysql.cluster" (Available, Writer, port 3306), which is highlighted with a red border.

Endpoint name	Status	Type	Port
aurora-cl-mysql.cluster-ro.us-east-1.rds.amazonaws.com	Available	Reader	3306
aurora-cl-mysql.cluster.us-east-1.rds.amazonaws.com	Available	Writer	3306

Connection utilities for Aurora MySQL

Some connection utilities you can use are the following:

- **Command line** – You can connect to an Amazon Aurora DB cluster by using tools like the MySQL command line utility. For more information on using the MySQL utility, see [mysql - the MySQL command line tool](#) in the MySQL documentation.
- **GUI** – You can use the MySQL Workbench utility to connect by using a UI interface. For more information, see the [Download MySQL workbench](#) page.
- **Applications** – You can use the MariaDB Connector/J utility to connect your applications to your Aurora DB cluster. For more information, see the [MariaDB Connector/J download](#) page.

Note

If you use the MariaDB Connector/J utility with an Aurora Serverless v1 DB cluster, use the prefix `jdbc:mariadb:aurora://` in your connection string. The `mariadb:aurora` parameter avoids the automatic DNS scan for failover targets. That scanning is not needed with Aurora Serverless v1 DB clusters and causes a delay in establishing the connection.

You can use SSL encryption on connections to an Aurora MySQL DB instance. For information, see [Using SSL/TLS with Aurora MySQL DB clusters \(p. 775\)](#).

Connecting with SSL for Aurora MySQL

To connect using SSL, use the MySQL utility as described in the following procedure. If you are using IAM database authentication, you must use an SSL connection. For information, see [IAM database authentication \(p. 1743\)](#).

Note

To connect to the cluster endpoint using SSL, your client connection utility must support Subject Alternative Names (SAN). If your client connection utility doesn't support SAN, you can connect directly to the instances in your Aurora DB cluster. For more information on Aurora endpoints, see [Amazon Aurora connection management \(p. 32\)](#).

To connect to a DB cluster with SSL using the MySQL utility

1. Download the public key for the Amazon RDS signing certificate.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1714\)](#).

2. Type the following command at a command prompt to connect to the primary instance of a DB cluster with SSL using the MySQL utility. For the `-h` parameter, substitute the endpoint DNS name for your primary instance. For the `-u` parameter, substitute the user ID of a database user account. For the `--ssl-ca` parameter, substitute the SSL certificate file name as appropriate. Type the master user password when prompted.

```
mysql -h mycluster-primary.123456789012.us-east-1.rds.amazonaws.com -u
admin_user -p --ssl-ca=[full path]rds-combined-ca-bundle.pem --ssl-verify-
server-cert
```

You should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 350
Server version: 5.6.10-log MySQL Community Server (GPL)

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

For general instructions on constructing RDS for MySQL connection strings and finding the public key for SSL connections, see [Connecting to a DB instance running the MySQL database engine](#).

Connecting with the Amazon Web Services JDBC Driver for MySQL (preview)

This is preview documentation for Amazon Web Services JDBC Driver for MySQL. It is subject to change.

The AWS JDBC Driver for MySQL (preview) is a client driver designed for the high availability of Aurora MySQL. The AWS JDBC Driver for MySQL is drop-in compatible with the MySQL Connector/J driver.

The AWS JDBC Driver for MySQL takes full advantage of the failover capabilities of Aurora MySQL. The AWS JDBC Driver for MySQL fully maintains a cache of the DB cluster topology and each DB instance's

role, either primary DB instance or Aurora Replica. It uses this topology to bypass the delays caused by DNS resolution so that a connection to the new primary DB instance is established as fast as possible.

For more information about the AWS JDBC Driver for MySQL and complete instructions for using it, see the [AWS JDBC Driver for MySQL GitHub repository](#).

Connecting to an Amazon Aurora PostgreSQL DB cluster

You can connect to a DB instance in your Amazon Aurora PostgreSQL DB cluster using the same tools that you use to connect to a PostgreSQL database. As part of this, you use the same public key for Secure Sockets Layer (SSL) connections. You can use the endpoint and port information from the primary instance or Aurora Replicas in your Aurora PostgreSQL DB cluster in the connection string of any script, utility, or application that connects to a PostgreSQL DB instance. In the connection string, specify the DNS address from the primary instance or Aurora Replica endpoint as the host parameter. Specify the port number from the endpoint as the port parameter.

When you have a connection to a DB instance in your Amazon Aurora PostgreSQL DB cluster, you can run any SQL command that is compatible with PostgreSQL.

In the details view for your Aurora PostgreSQL DB cluster you can find the cluster endpoint name, status, type, and port number. You use the endpoint and port number in your PostgreSQL connection string. For example, if an endpoint value is `mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com`, then you specify the following values in a PostgreSQL connection string:

- For host or host name, specify `mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com`
- For port, specify 5432 or the port value you used when you created the DB cluster

The cluster endpoint connects you to the primary instance for the DB cluster. You can perform both read and write operations using the cluster endpoint. Your DB cluster can also have up to 15 Aurora Replicas that support read-only access to the data in your DB cluster. Each DB instance in the Aurora cluster (that is, the primary instance and each Aurora Replica) has a unique endpoint that is independent of the cluster endpoint. This unique endpoint allows you to connect to a specific DB instance in the cluster directly. The cluster endpoint always points to the primary instance. If the primary instance fails and is replaced, the cluster endpoint points to the new primary instance.

To view the cluster endpoint (writer endpoint), choose **Databases** on the Amazon RDS console and choose the name of the DB cluster to show the DB cluster details.

The screenshot shows the AWS RDS console interface for managing databases. The top navigation bar includes 'RDS' and 'Databases' with the specific database name 'aurora-cl-postgresql'. Below the navigation is the database name 'aurora-cl-postgresql' with 'Modify' and 'Actions' buttons. A 'Related' section with a search bar follows. The main content area displays a table for 'DB identifier' with columns: DB identifier, Role, Engine, Region & AZ, and Size. It lists three entries: 'aurora-cl-postgresql' (Regional, Aurora PostgreSQL, us-east-1, 2 instances), 'aurora-cl-postgresql-instance-1' (Writer, Aurora PostgreSQL, us-east-1a, db.r5.large), and 'aurora-cl-postgresql-instance-1-us-east-1b' (Reader, Aurora PostgreSQL, us-east-1b, db.r5.large). Below the table are tabs for 'Connectivity & security' (selected), 'Monitoring', 'Logs & events', 'Configuration', 'Maintenance & backups', and 'Tags'. The 'Endpoints (2)' section shows two endpoints: 'aurora-cl-postgresql.cluster-ro...' (us-east-1.rds.amazonaws.com) and 'aurora-cl-postgresql.cluster...' (us-east-1.rds.amazonaws.com). The second endpoint is highlighted with a red border. Buttons for 'Edit', 'Delete', and 'Create custom endpoint' are available. A 'Manage IAM roles' button is also present.

DB identifier	Role	Engine	Region & AZ	Size
aurora-cl-postgresql	Regional	Aurora PostgreSQL	us-east-1	2 instances
aurora-cl-postgresql-instance-1	Writer	Aurora PostgreSQL	us-east-1a	db.r5.large
aurora-cl-postgresql-instance-1-us-east-1b	Reader	Aurora PostgreSQL	us-east-1b	db.r5.large

Connection utilities for Aurora PostgreSQL

Some connection utilities you can use are the following:

- **Command line** – You can connect to an Amazon Aurora PostgreSQL DB instance by using tools like `psql`, the PostgreSQL interactive terminal. For more information on using the PostgreSQL interactive terminal, see [psql](#) in the PostgreSQL documentation.
- **GUI** – You can use the pgAdmin utility to connect to a PostgreSQL DB instance by using a UI interface. For more information, see the [Download](#) page from the pgAdmin website.
- **Applications** – You can use the PostgreSQL JDBC driver to connect your applications to your PostgreSQL DB instance. For more information, see the [Download](#) page from the PostgreSQL JDBC driver website.

Connecting with the Amazon Web Services JDBC Driver for PostgreSQL (preview)

This is preview documentation for Amazon Web Services JDBC Driver for PostgreSQL. It is subject to change.

The AWS JDBC Driver for PostgreSQL (preview) is a client driver designed for the high availability of Aurora PostgreSQL. The AWS JDBC Driver for PostgreSQL is drop-in compatible with the PostgreSQL JDBC Driver.

The AWS JDBC Driver for PostgreSQL takes full advantage of the failover capabilities of Aurora PostgreSQL. The AWS JDBC Driver for PostgreSQL fully maintains a cache of the DB cluster topology and each DB instance's role, either primary DB instance or Aurora Replica. It uses this topology to bypass the delays caused by DNS resolution so that a connection to the new primary DB instance is established as fast as possible.

For more information about the AWS JDBC Driver for PostgreSQL and complete instructions for using it, see the [AWS JDBC Driver for PostgreSQL GitHub repository](#).

Troubleshooting Aurora connection failures

Common causes of connection failures to a new Aurora DB cluster include the following:

- **Security group in the VPC doesn't allow access** – Your VPC needs to allow connections from your device or from an Amazon EC2 instance by proper configuration of the Security group in the VPC. To resolve, modify your VPC's Security group Inbound rules to allow connections. For an example, see [Create a VPC and subnets \(p. 1793\)](#).
- **Port blocked by firewall rules** – Check the value of the port configured for your Aurora DB cluster. If a firewall rule blocks that port, you can re-create the instance using a different port.
- **Incomplete or incorrect IAM configuration** – If you created your Aurora DB instance to use IAM-based authentication, make sure that it's properly configured. For more information, see [IAM database authentication \(p. 1743\)](#).

For more information about troubleshooting Aurora DB connection issues, see [Can't connect to Amazon RDS DB instance \(p. 1814\)](#).

Using Amazon RDS Proxy

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. By using RDS Proxy, you can also enforce AWS Identity and Access Management (IAM) authentication for databases, and securely store credentials in AWS Secrets Manager.

Note

RDS Proxy is fully compatible with MySQL and PostgreSQL. You can enable RDS Proxy for most applications with no code changes.

Using RDS Proxy, you can handle unpredictable surges in database traffic that otherwise might cause issues due to oversubscribing connections or creating new connections at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool without the memory and CPU overhead of opening a new database connection each time. To protect the database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can't be served immediately from the pool of connections. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that can be served with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

Topics

- [Supported engines and Region availability for RDS Proxy \(p. 288\)](#)

Supported engines and Region availability for RDS Proxy

For information about database engine version support and availability of RDS Proxy in a given AWS Region, see [Amazon RDS Proxy](#).

Quotas and limitations for RDS Proxy

The following quotas and limitations apply to RDS Proxy:

- You can have up to 20 proxies for each AWS account ID. If your application requires more proxies, you can request additional proxies by opening a ticket with the AWS Support organization.
- Each proxy can have up to 200 associated Secrets Manager secrets. Thus, each proxy can connect to up to 200 different user accounts at any given time.
- You can create, view, modify, and delete up to 20 endpoints for each proxy. These endpoints are in addition to the default endpoint that's automatically created for each proxy.
- In an Aurora cluster, all of the connections using the default proxy endpoint are handled by the Aurora writer instance. To perform load balancing for read-intensive workloads, you can create a read-only endpoint for a proxy. That endpoint passes connections to the reader endpoint of the cluster. That way, your proxy connections can take advantage of Aurora read scalability. For more information, see [Overview of proxy endpoints \(p. 315\)](#).

For RDS DB instances in replication configurations, you can associate a proxy only with the writer DB instance, not a read replica.

- You can't use RDS Proxy with Aurora Serverless clusters.
- Using RDS Proxy with Aurora clusters that are part of an Aurora global database isn't currently supported.
- Your RDS Proxy must be in the same virtual private cloud (VPC) as the database. The proxy can't be publicly accessible, although the database can be. For example, if you're prototyping on a local host, you can't connect to your RDS Proxy unless you set up dedicated networking. This is the case because your local host is outside of the proxy's VPC.

Note

For Aurora DB clusters, you can turn on cross-VPC access. To do this, create an additional endpoint for a proxy and specify a different VPC, subnets, and security groups with that endpoint. For more information, see [Accessing Aurora and RDS databases across VPCs \(p. 319\)](#).

- You can't use RDS Proxy with a VPC that has its tenancy set to dedicated.
- If you use RDS Proxy with an RDS DB instance or Aurora DB cluster that has IAM authentication enabled, make sure that all users who connect through a proxy authenticate through user names and passwords. See [Setting up AWS Identity and Access Management \(IAM\) policies \(p. 297\)](#) for details about IAM support in RDS Proxy.
- You can't use RDS Proxy with custom DNS.
- RDS Proxy is available for the MySQL and PostgreSQL engine families.
- Each proxy can be associated with a single target DB instance or cluster. However, you can associate multiple proxies with the same DB instance or cluster.

The following RDS Proxy limitations apply to MySQL:

- RDS Proxy doesn't support the MySQL sha256_password and caching_sha2_password authentication plugins. These plugins implement SHA-256 hashing for user account passwords.
- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
- You can't use RDS Proxy with an RDS for MySQL DB instance that has the read_only parameter in its DB parameter group set to 1.
- Proxies don't support MySQL compressed mode. For example, they don't support the compression used by the --compress or -C options of the mysql command.
- Some SQL statements and functions can change the connection state without causing pinning. For the most current pinning behavior, see [Avoiding pinning \(p. 312\)](#).

The following RDS Proxy limitations apply to PostgreSQL:

- Currently, all proxies listen on port 5432 for PostgreSQL.
- For PostgreSQL, RDS Proxy doesn't currently support canceling a query from a client by issuing a `CancelRequest`. This is the case for example, when you cancel a long-running query in an interactive `psql` session by using `Ctrl+C`.
- The results of the PostgreSQL function `lastval` aren't always accurate. As a work-around, use the `INSERT` statement with the `RETURNING` clause.
- RDS Proxy doesn't multiplex connections when your client application drivers use the PostgreSQL extended query protocol.

Planning where to use RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

- Any DB instance or cluster that encounters "too many connections" errors is a good candidate for associating with a proxy. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB instance or cluster.
- For DB instances or clusters that use smaller AWS instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
- You can monitor certain Amazon CloudWatch metrics to determine whether a DB instance or cluster is approaching certain types of limit. These limits are for the number of connections and the memory associated with connection management. You can also monitor certain CloudWatch metrics to determine whether a DB instance or cluster is handling many short-lived connections. Opening and closing such connections can impose performance overhead on your database. For information about the metrics to monitor, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 324\)](#).
- AWS Lambda functions can also be good candidates for using a proxy. These functions make frequent short database connections that benefit from connection pooling offered by RDS Proxy. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- Applications that use languages and frameworks such as PHP and Ruby on Rails are typically good candidates for using a proxy. Such applications typically open and close large numbers of database connections, and don't have built-in connection pooling mechanisms.
- Applications that keep a large number of connections open for long periods are typically good candidates for using a proxy. Applications in industries such as software as a service (SaaS) or ecommerce often minimize the latency for database requests by leaving connections open. With RDS Proxy, an application can keep more connections open than it can when connecting directly to the DB instance or cluster.
- You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting up such authentication for all DB instances and clusters. If so, you can leave the existing authentication methods in place and delegate the authentication to a proxy. The proxy can enforce the authentication policies for client connections for particular applications. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). To ensure overall high availability for your database, deploy your Amazon RDS DB instance or Aurora cluster in a Multi-AZ configuration.

RDS Proxy concepts and terminology

You can simplify connection management for your Amazon RDS DB instances and Amazon Aurora DB clusters by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an active way first by understanding the database protocol. It then adjusts its behavior based on the SQL operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database. The database needs less memory and CPU resources when applications open many simultaneous connections. It also doesn't require logic in your applications to close and reopen connections that stay idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). The computation, memory, and storage for RDS Proxy are independent of your RDS DB instances and Aurora DB clusters. This separation helps lower overhead on your database servers, so that they can devote their resources to serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling based on your database workload.

Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described in the sections that follow. You see the proxies represented in the RDS console on the [Proxies](#) page.

Each proxy handles connections to a single RDS DB instance or Aurora DB cluster. The proxy automatically determines the current writer instance for RDS Multi-AZ DB instances and Aurora provisioned clusters. For Aurora multi-master clusters, the proxy connects to one of the writer instances and uses the other writer instances as hot standby targets.

The connections that a proxy keeps open and available for your database application to use make up the *connection pool*.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called *multiplexing*. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called *borrowing* the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called *pinning*.

A proxy has a default endpoint. You connect to this endpoint when you work with an RDS DB instance or Aurora DB cluster, instead of connecting to the read/write endpoint that connects directly to the instance or cluster. The special-purpose endpoints for an Aurora cluster remain available for you to use. For Aurora DB clusters, you can also create additional read/write and read-only endpoints. For more information, see [Overview of proxy endpoints \(p. 315\)](#).

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within an Aurora cluster. If you are using other AWS services such as AWS Lambda to connect to RDS databases, you change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This *target group* embodies the RDS DB instance or Aurora DB cluster that the proxy can connect to. For an Aurora cluster, by default the target group is associated with all the DB instances in that cluster. That way, the proxy can connect to whichever Aurora DB instance is promoted to be the writer instance in the cluster. The RDS DB instance associated with a proxy, or the Aurora DB cluster and its instances, are called the *targets* of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An *engine family* is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

Connection pooling

Each proxy performs connection pooling for the writer instance of its associated RDS or Aurora database. *Connection pooling* is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one, such as Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With *multiplexing*, RDS Proxy performs all the operations for a transaction using one underlying database connection, then can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of "too many connections" errors.

RDS Proxy security

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and AWS Identity and Access Management (IAM). For general information about those security features, see [Security in Amazon Aurora \(p. 1706\)](#). If you aren't familiar with how RDS and Aurora work with authentication, authorization, and other areas of security, make sure to familiarize yourself with how RDS and Aurora work with those areas first.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.2, even if the underlying DB instance supports only TLS 1.0 or 1.1. You can connect to the proxy using an IAM role, even if the proxy connects to the database using the native user and password authentication method. By using this technique, you can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.

You store the database credentials used by RDS Proxy in AWS Secrets Manager. Each database user for the RDS DB instance or Aurora DB cluster accessed by a proxy must have a corresponding secret in Secrets Manager. You can also set up IAM authentication for users of RDS Proxy. By doing so, you can enforce IAM authentication for database access even if the databases use native password authentication. We recommend using these security features instead of embedding database credentials in your application code.

Using TLS/SSL with RDS Proxy

You can connect to RDS Proxy using the TLS/SSL protocol.

Note

RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you use RDS Proxy, when you rotate your TLS/SSL certificate you don't need to update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting **Require Transport Layer Security** when you create or modify a proxy.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For RDS for MySQL and Aurora MySQL, specify the requirement on the client side with the `--ssl-mode` parameter when you run the `mysql` command.
- For Amazon RDS PostgreSQL and Aurora PostgreSQL, specify `sslmode=require` as part of the `conninfo` string when you run the `psql` command.

RDS Proxy supports TLS protocol version 1.0, 1.1, and 1.2. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the `--ssl-mode` option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

PREFERRED

SSL is the first choice, but it isn't required.

DISABLED

No SSL is allowed.

REQUIRED

Enforce SSL.

VERIFY_CA

Enforce SSL and verify the certificate authority (CA).

VERIFY_IDENTITY

Enforce SSL and verify the CA and CA hostname.

Note

You can use the SSL mode `VERIFY_IDENTITY` when connecting to the default proxy endpoint. You can't use that SSL mode when you connect to proxy endpoints that you create.

When using a client with `--ssl-mode VERIFY_CA` or `VERIFY_IDENTITY`, specify the `--ssl-ca` option pointing to a CA in `.pem` format. For a `.pem` file that you can use, download the [Amazon root CA 1 trust store](#) from Amazon Trust Services.

RDS Proxy uses wildcard certificates, which apply to both a domain and its subdomains. If you use the `mysql` client to connect with SSL mode `VERIFY_IDENTITY`, currently you must use the MySQL 8.0-compatible `mysql` command.

Failover

Failover is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to RDS DB instances in a Multi-AZ configuration, and Aurora DB clusters with one or more reader instances in addition to the writer instance.

Connecting through a proxy makes your application more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. Doing so helps to speed up and simplify the failover process. The result is faster failover that's less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on that database. Any existing database connections are disrupted and your application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted to take the place of the one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection rates and more open connections. It offloads the expensive overhead of frequent reconnects from the database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This approach is particularly important for TLS connections, where setup costs are significant.

Transactions

All the statements within a single transaction always use the same underlying database connection. The connection becomes available for use by a different session when the transaction ends. Using the transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the RDS for MySQL or Aurora MySQL `autocommit` setting is enabled.
- Conversely, when the `autocommit` setting is disabled, the first statement you issue in a session begins a new transaction. Thus, if you enter a sequence of `SELECT`, `INSERT`, `UPDATE`, and other data manipulation language (DML) statements, connection reuse doesn't happen until you issue a `COMMIT`, `ROLLBACK`, or otherwise end the transaction.
- Entering a data definition language (DDL) statement causes the transaction to end after that statement completes.

RDS Proxy detects when a transaction ends through the network protocol used by the database client application. Transaction detection doesn't rely on keywords such as `COMMIT` or `ROLLBACK` appearing in the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session to a different connection. In these cases, it turns off multiplexing for that connection the remainder of your session. The same rule applies if RDS Proxy can't be certain that multiplexing is practical for the session. This operation is called *pinning*. For ways to detect and minimize pinning, see [Avoiding pinning \(p. 312\)](#).

Getting started with RDS Proxy

In the following sections, you can find how to set up RDS Proxy. You can also find how to set the related security options that control who can access each proxy and how each proxy connects to DB instances.

Topics

- [Setting up network prerequisites \(p. 295\)](#)
- [Setting up database credentials in AWS Secrets Manager \(p. 296\)](#)
- [Setting up AWS Identity and Access Management \(IAM\) policies \(p. 297\)](#)
- [Creating an RDS Proxy \(p. 299\)](#)
- [Viewing an RDS Proxy \(p. 302\)](#)
- [Connecting to a database through RDS Proxy \(p. 304\)](#)

Setting up network prerequisites

Using RDS Proxy requires you to have a common virtual private cloud (VPC) between your Aurora DB cluster or RDS DB instance and RDS Proxy. This VPC should have a minimum of two subnets that are in different Availability Zones. Your account can either own these subnets or share them with other accounts. For information about VPC sharing, see [Work with shared VPCs](#). Your client application resources such as Amazon EC2, Lambda, or Amazon ECS can be in the same VPC or in a separate VPC from the proxy. Note that if you've successfully connected to any RDS DB instances or Aurora DB clusters, you already have the required network resources.

If you're just getting started with RDS or Aurora, you can learn the basics of connecting to a database by following the procedures in [Setting up your environment for Amazon Aurora \(p. 84\)](#). You can also follow the tutorial in [Getting started with Amazon Aurora \(p. 89\)](#).

The following Linux example shows AWS CLI commands that examine the VPCs and subnets owned by your AWS account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*[].[VpcId,SubnetId]' --output text | sort
```

The following Linux example shows AWS CLI commands to determine the subnet IDs corresponding to a specific Aurora DB cluster or RDS DB instance. For an Aurora cluster, first you find the ID for one of the associated DB instances. You can extract the subnet IDs used by that DB instance by examining the nested fields within the `DBSubnetGroup` and `Subnets` attributes in the describe output for the DB instance. You specify some or all of those subnet IDs when setting up a proxy for that database server.

```
$ # Optional first step, only needed if you're starting from an Aurora cluster. Find the ID
of any DB instance in the cluster.
$ aws rds describe-db-clusters --db-cluster-identifier my_cluster_id --query '*[].[DBClusterMembers][0|[0|[*].DBInstanceIdentifier' --output text
my_instance_id
instance_id_2
instance_id_3
...
$ # From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet
IDs.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].[DBSubnetGroup][0|[0|[Subnets][0|[*].SubnetIdentifier' --output text
```

```
subnet_id_1
subnet_id_2
subnet_id_3
...
```

As an alternative, you can first find the VPC ID for the DB instance. Then you can examine the VPC to find its subnets. The following Linux example shows how.

```
$ # From the DB instance, find the VPC.
$ aws rds describe-db-instances --db-instance-identifier my_instance_id --query '*[].[DBSubnetGroup|[0]|[]].VpcId' --output text
my_vpc_id

$ aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '*[].[SubnetId]' --output text
subnet_id_1
subnet_id_2
subnet_id_3
subnet_id_4
subnet_id_5
subnet_id_6
```

Setting up database credentials in AWS Secrets Manager

For each proxy that you create, you first use the Secrets Manager service to store sets of user name and password credentials. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the RDS DB instance or Aurora DB cluster.

In Secrets Manager, you create these secrets with values for the **username** and **password** fields. Doing so allows the proxy to connect to the corresponding database users on whichever RDS DB instances or Aurora DB clusters that you associate with the proxy. To do this, you can use the setting **Credentials for other database**, **Credentials for RDS database**, or **Other type of secrets**. Fill in the appropriate values for the **User name** and **Password** fields, and placeholder values for any other required fields. The proxy ignores other fields such as **Host** and **Port** if they're present in the secret. Those details are automatically supplied by the proxy.

You can also choose **Other type of secrets**. In this case, you create the secret with keys named **username** and **password**.

Because the secrets used by your proxy aren't tied to a specific database server, you can reuse a secret across multiple proxies if you use the same credentials across multiple database servers. For example, you might use the same credentials across a group of development and test servers.

To connect through the proxy as a specific user, make sure that the password associated with a secret matches the database password for that user. If there's a mismatch, you can update the associated secret in Secrets Manager. In this case, you can still connect to other accounts where the secret credentials and the database passwords do match.

When you create a proxy through the AWS CLI or RDS API, you specify the Amazon Resource Names (ARNs) of the corresponding secrets for all the DB user accounts that the proxy can access. In the AWS Management Console, you choose the secrets by their descriptive names.

For instructions about creating secrets in Secrets Manager, see the [Creating a secret](#) page in the Secrets Manager documentation. Use one of the following techniques:

- Use [Secrets Manager](#) in the console.
- To use the CLI to create a Secrets Manager secret for use with RDS Proxy, use a command such as the following.

```
aws secretsmanager create-secret \
--name "secret_name"
--description "secret_description"
--region region_name
--secret-string '{"username":"db_user","password":"db_user_password"}'
```

For example, the following commands create Secrets Manager secrets for two database users, one named admin and the other named app-user.

```
aws secretsmanager create-secret \
--name admin_secret_name --description "db admin user" \
--secret-string '{"username":"admin","password":"choose_your_own_password"}'

aws secretsmanager create-secret \
--name proxy_secret_name --description "application user" \
--secret-string '{"username":"app-user","password":"choose_your_own_password"}'
```

To see the secrets owned by your AWS account, use a command such as the following.

```
aws secretsmanager list-secrets
```

When you create a proxy using the CLI, you pass the Amazon Resource Names (ARNs) of one or more secrets to the --auth parameter. The following Linux example shows how to prepare a report with only the name and ARN of each secret owned by your AWS account. This example uses the --output table parameter that is available in AWS CLI version 2. If you are using AWS CLI version 1, use --output text instead.

```
aws secretsmanager list-secrets --query '*[].[Name,ARN]' --output table
```

To verify that you stored the correct credentials and in the right format in a secret, use a command such as the following. Substitute the short name or the ARN of the secret for *your_secret_name*.

```
aws secretsmanager get-secret-value --secret-id your_secret_name
```

The output should include a line displaying a JSON-encoded value like the following.

```
"SecretString": "{\"username\":\"your_username\",\"password\":\"your_password\"}",
```

Setting up AWS Identity and Access Management (IAM) policies

After you create the secrets in Secrets Manager, you create an IAM policy that can access those secrets. For general information about using IAM with RDS and Aurora, see [Identity and access management in Amazon Aurora \(p. 1724\)](#).

Tip

The following procedure applies if you use the IAM console. If you use the AWS Management Console for RDS, RDS can create the IAM policy for you automatically. In that case, you can skip the following procedure.

To create an IAM policy that accesses your Secrets Manager secrets for use with your proxy

1. Sign in to the IAM console. Follow the [Create role](#) process, as described in [Creating IAM roles](#). Include the [Add Role to Database](#) step.
2. For the new role, perform the [Add inline policy](#) step. Use the same general procedures as in [Editing IAM policies](#). Paste the following JSON into the JSON text box. Substitute your own account ID.

Substitute your AWS Region for `us-east-2`. Substitute the Amazon Resource Names (ARNs) for the secrets that you created. For the `kms:Decrypt` action, substitute the ARN of the default AWS KMS key or your own KMS key depending on which one you used to encrypt the Secrets Manager secrets.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "secretsmanager:GetSecretValue",
            "Resource": [
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"
            ]
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:us-east-2:account_id:key/key_id",
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
                }
            }
        }
    ]
}
```

3. Edit the trust policy for this IAM role. Paste the following JSON into the JSON text box.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

The following commands perform the same operation through the AWS CLI.

```
PREFIX=choose_an_identifier

aws iam create-role --role-name choose_role_name \
--assume-role-policy-document '{"Version":"2012-10-17","Statement": [{"Effect":"Allow","Principal":{"Service": ["rds.amazonaws.com"]},"Action":"sts:AssumeRole"}]}'

aws iam put-role-policy --role-name same_role_name_as_previous \
--policy-name $PREFIX-secret-reader-policy --policy-document """
same_json_as_in_previous_example
"""

aws kms create-key --description "$PREFIX-test-key" --policy """
{
```

```

"Id": "$PREFIX-kms-policy",
"Version": "2012-10-17",
"Statement":
[
    {
        "Sid": "Enable IAM User Permissions",
        "Effect": "Allow",
        "Principal": {"AWS": "arn:aws:iam::account_id:root"},
        "Action": "kms:*", "Resource": "*"
    },
    {

"""

```

Creating an RDS Proxy

To manage connections for a specified set of DB instances, you can create a proxy. You can associate a proxy with an RDS for MySQL DB instance, PostgreSQL DB instance, or an Aurora DB cluster.

AWS Management Console

To create a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Choose **Create proxy**.
4. Choose all the settings for your proxy.

For **Proxy configuration**, provide information for the following:

- **Proxy identifier.** Specify a name of your choosing, unique within your AWS account ID and current AWS Region.
- **Engine compatibility.** Choose either **MySQL** or **POSTGRESQL**.
- **Require Transport Layer Security.** Choose this setting if you want the proxy to enforce TLS/SSL for all client connections. When you use an encrypted or unencrypted connection to a proxy, the proxy uses the same encryption setting when it makes a connection to the underlying database.
- **Idle client connection timeout.** Choose a time period that a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes). A client connection is considered idle when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections.

Consider lowering the idle client connection timeout if you want the proxy to proactively remove stale connections. If your workload is spiking, consider raising the idle client connection timeout to save the cost of establishing connections.

For **Target group configuration**, provide information for the following:

- **Database.** Choose one RDS DB instance or Aurora DB cluster to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in [Creating an Amazon Aurora DB cluster \(p. 125\)](#). Then try creating the proxy again.
- **Connection pool maximum connections.** Specify a value from 1 through 100. This setting represents the percentage of the `max_connections` value that RDS Proxy can use for its connections. If you only intend to use one proxy with this DB instance or cluster, you can set this value to 100. For details about how RDS Proxy uses this setting, see [MaxConnectionsPercent \(p. 311\)](#).
- **Session pinning filters.** (Optional) This is an advanced setting, for troubleshooting performance issues with particular applications. Currently, the only choice is `EXCLUDE_VARIABLE_SETS`. Choose a filter only if both of following are true: Your application isn't reusing connections due to certain kinds of SQL statements, and you can verify that reusing connections with those SQL statements doesn't affect application correctness. For more information, see [Avoiding pinning \(p. 312\)](#).
- **Connection borrow timeout.** In some cases, you might expect the proxy to sometimes use all available database connections. In such cases, you can specify how long the proxy waits for a database connection to become available before returning a timeout error. You can specify a period up to a maximum of five minutes. This setting only applies when the proxy has the maximum number of connections open and all connections are already in use.
- **Initialization query.** (Optional) You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with `SET` statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single `SET` statement, such as `SET x=1, y=2`. Initialization query is not currently supported for PostgreSQL.

For **Connectivity**, provide information for the following:

- **Secrets Manager secrets.** Choose at least one Secrets Manager secret that contains DB user credentials for the RDS DB instance or Aurora DB cluster that you intend to access with this proxy.

- **IAM role.** Choose an IAM role that has permission to access the Secrets Manager secrets that you chose earlier. You can also choose for the AWS Management Console to create a new IAM role for you and use that.
- **IAM Authentication.** Choose whether to require or disallow IAM authentication for connections to your proxy. The choice of IAM authentication or native database authentication applies to all DB users that access this proxy.
- **Subnets.** This field is prepopulated with all the subnets associated with your VPC. You can remove any subnets that you don't need for this proxy. You must leave at least two subnets.

Provide additional connectivity configuration:

- **VPC security group.** Choose an existing VPC security group. You can also choose for the AWS Management Console to create a new security group for you and use that.

Note

This security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group. When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see [Work with shared VPCs](#).

(Optional) Provide advanced configuration:

- **Enable enhanced logging.** You can enable this setting to troubleshoot proxy compatibility or performance issues.

When this setting is enabled, RDS Proxy includes detailed information about SQL statements in its logs. This information helps you to debug issues involving SQL behavior or the performance and scalability of the proxy connections. The debug information includes the text of SQL statements that you submit through the proxy. Thus, only enable this setting when needed for debugging, and only when you have security measures in place to safeguard any sensitive information that appears in the logs.

To minimize overhead associated with your proxy, RDS Proxy automatically turns this setting off 24 hours after you enable it. Enable it temporarily to troubleshoot a specific issue.

5. Choose **Create Proxy**.

AWS CLI

To create a proxy, use the AWS CLI command [create-db-proxy](#). The --engine-family value is case-sensitive.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-proxy \
--db-proxy-name proxy_name \
--engine-family { MYSQL | POSTGRESQL } \
--auth ProxyAuthenticationConfig_JSON_string \
--role-arn iam_role \
--vpc-subnet-ids space_separated_list \
```

```
[--vpc-security-group-ids space-separated_list] \
[--require-tls | --no-require-tls] \
[--idle-client-timeout value] \
[--debug-logging | --no-debug-logging] \
[--tags comma-separated_list]
```

For Windows:

```
aws rds create-db-proxy ^
--db-proxy-name proxy_name ^
--engine-family { MYSQL | POSTGRESOL } ^
--auth ProxyAuthenticationConfig_JSON_string ^
--role-arn iam_role ^
--vpc-subnet-ids space-separated_list ^
[--vpc-security-group-ids space-separated_list] ^
[--require-tls | --no-require-tls] ^
[--idle-client-timeout value] ^
[--debug-logging | --no-debug-logging] ^
[--tags comma-separated_list]
```

Tip

If you don't already know the subnet IDs to use for the `--vpc-subnet-ids` parameter, see [Setting up network prerequisites \(p. 295\)](#) for examples of how to find the subnet IDs that you can use.

Note

The security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.

When using a shared VPC, you can't use the default security group for the VPC, or one that belongs to another account. Choose a security group that belongs to your account. If one doesn't exist, create one. For more information about this limitation, see [Work with shared VPCs](#).

To create the required information and associations for the proxy, you also use the `register-db-proxy-targets` command. Specify the target group name `default`. RDS Proxy automatically creates a target group with this name when you create each proxy.

```
aws rds register-db-proxy-targets
--db-proxy-name value
[--target-group-name target_group_name]
[--db-instance-identifiers space-separated_list] # rds db instances, or
[--db-cluster-identifiers cluster_id]           # rds db cluster (all instances), or
[--db-cluster-endpoint endpoint_name]          # rds db cluster endpoint (all
instances)
```

RDS API

To create an RDS proxy, call the Amazon RDS API operation [CreateDBProxy](#). You pass a parameter with the `AuthConfig` data structure.

RDS Proxy automatically creates a target group named `default` when you create each proxy. You associate an RDS DB instance or Aurora DB cluster with the target group by calling the function [RegisterDBProxyTargets](#).

Viewing an RDS Proxy

After you create one or more RDS proxies, you can view them all to examine their configuration details and choose which ones to modify, delete, and so on.

Any database applications that use the proxy require the proxy endpoint to use in the connection string.

AWS Management Console

To view your proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the RDS Proxy.
3. In the navigation pane, choose **Proxies**.
4. Choose the name of an RDS proxy to display its details.
5. On the details page, the **Target groups** section shows how the proxy is associated with a specific RDS DB instance or Aurora DB cluster. You can follow the link to the **default** target group page to see more details about the association between the proxy and the database. This page is where you see settings that you specified when creating the proxy, such as maximum connection percentage, connection borrow timeout, engine compatibility, and session pinning filters.

CLI

To view your proxy using the CLI, use the `describe-db-proxies` command. By default, it displays all proxies owned by your AWS account. To see details for a single proxy, specify its name with the `--db-proxy-name` parameter.

```
aws rds describe-db-proxies [--db-proxy-name proxy_name]
```

To view the other information associated with the proxy, use the following commands.

```
aws rds describe-db-proxy-target-groups --db-proxy-name proxy_name  
aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run `describe-db-proxies`.
2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run `describe-db-proxy-target-groups` `--db-proxy-name` and use the name of the proxy as the parameter value.
3. To see the details of the RDS DB instance or Aurora DB cluster associated with the returned target group, run `describe-db-proxy-targets`.

RDS API

To view your proxies using the RDS API, use the `DescribeDBProxies` operation. It returns values of the `DBProxy` data type.

To see details of the connection settings for the proxy, use the proxy identifiers from this return value with the `DescribeDBProxyTargetGroups` operation. It returns values of the `DBProxyTargetGroup` data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the `DescribeDBProxyTargets` operation. It returns values of the `DBProxyTarget` data type.

Connecting to a database through RDS Proxy

You connect to an RDS DB instance or Aurora DB cluster through a proxy in generally the same way as you connect directly to the database. The main difference is that you specify the proxy endpoint instead of the instance or cluster endpoint. For an Aurora DB cluster, by default all proxy connections have read/write capability and use the writer instance. If you normally use the reader endpoint for read-only connections, you can create an additional read-only endpoint for the proxy and use that endpoint the same way. For more information, see [Overview of proxy endpoints \(p. 315\)](#).

Topics

- [Connecting to a proxy using native authentication \(p. 304\)](#)
- [Connecting to a proxy using IAM authentication \(p. 304\)](#)
- [Considerations for connecting to a proxy with PostgreSQL \(p. 305\)](#)

Connecting to a proxy using native authentication

Use the following basic steps to connect to a proxy using native authentication:

1. Find the proxy endpoint. In the AWS Management Console, you can find the endpoint on the details page for the corresponding proxy. With the AWS CLI, you can use the `describe-db-proxies` command. The following example shows how.

```
# Add --output text to get output as a simple tab-separated list.
$ aws rds describe-db-proxies --query '*[*].{DBProxyName:DBProxyName,Endpoint:Endpoint}'
[
    [
        {
            "Endpoint": "the-proxy.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy"
        },
        {
            "Endpoint": "the-proxy-other-secret.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-other-secret"
        },
        {
            "Endpoint": "the-proxy-rds-secret.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-rds-secret"
        },
        {
            "Endpoint": "the-proxy-t3.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-t3"
        }
    ]
]
```

2. Specify that endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the `mysql -h` option or `psql -h` option.
3. Supply the same database user name and password as you usually do.

Connecting to a proxy using IAM authentication

When you use IAM authentication with RDS Proxy, set up your database users to authenticate with regular user names and passwords. The IAM authentication applies to RDS Proxy retrieving the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn't go through IAM.

To connect to RDS Proxy using IAM authentication, follow the same general procedure as for connecting to an RDS DB instance or Aurora cluster using IAM authentication. For general information about using IAM with RDS and Aurora, see [Security in Amazon Aurora \(p. 1706\)](#).

The major differences in IAM usage for RDS Proxy include the following:

- You don't configure each individual database user with an authorization plugin. The database users still have regular user names and passwords within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager.

The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager.

- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see [Connecting to your DB cluster using IAM authentication \(p. 1750\)](#).
- In the direct database IAM authentication case, you selectively choose database users and configure them to be identified with a special authentication plugin. You can then connect to those users using IAM authentication.

In the proxy use case, you provide the proxy with Secrets that contain some user's user name and password (native authentication). You then connect to the proxy using IAM authentication. Here, you do this by generating an authentication token with the proxy endpoint, not the database endpoint. You also use a user name that matches one of the user names for the secrets that you provided.

- Make sure that you use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.

You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
"Resource": "arn:aws:rds-db:us-east-2:1234567890:dbuser:prx-ABCDEFGHIJKL01234/db_user"
```

Considerations for connecting to a proxy with PostgreSQL

For PostgreSQL, when a client starts a connection to a PostgreSQL database, it sends a startup message that includes pairs of parameter name and value strings. For details, see the [StartupMessage](#) in [PostgreSQL message formats](#) in the PostgreSQL documentation.

When connecting through an RDS proxy, the startup message can include the following currently recognized parameters:

- `user`
- `database`
- `replication`

The startup message can also include the following additional runtime parameters:

- `application_name`
- `client_encoding`
- `DateStyle`
- `TimeZone`
- `extra_float_digits`

For more information about PostgreSQL messaging, see the [Frontend/Backend protocol](#) in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC we recommend the following to avoid pinning:

- Set the JDBC connection parameter `assumeMinServerVersion` to at least 9.0 to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET extra_float_digits = 3`.
- Set the JDBC connection parameter `ApplicationName` to `any/your-application-name` to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET application_name = "PostgreSQL JDBC Driver"`. Note the JDBC parameter is `ApplicationName` but the PostgreSQL `StartupMessage` parameter is `application_name`.
- Set the JDBC connection parameter `preferQueryMode` to `extendedForPrepared` to avoid pinning. The `extendedForPrepared` ensures that the extended mode is used only for prepared statements.

The default for the `preferQueryMode` parameter is `extended`, which uses the extended mode for all queries. The extended mode uses a series of `Prepare`, `Bind`, `Execute`, and `Sync` requests and corresponding responses. This type of series causes connection pinning in an RDS proxy.

For more information, see [Avoiding pinning \(p. 312\)](#). For more information about connecting using JDBC, see [Connecting to the database](#) in the PostgreSQL documentation.

Managing an RDS Proxy

Following, you can find an explanation of how to manage RDS Proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.

Topics

- [Modifying an RDS Proxy \(p. 306\)](#)
- [Adding a new database user \(p. 310\)](#)
- [Changing the password for a database user \(p. 311\)](#)
- [Configuring connection settings \(p. 311\)](#)
- [Avoiding pinning \(p. 312\)](#)
- [Deleting an RDS Proxy \(p. 314\)](#)

Modifying an RDS Proxy

You can change certain settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

AWS Management Console

To modify the settings for a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can modify the following:

- **Proxy identifier** – Rename the proxy by entering a new identifier.
 - **Require Transport Layer Security** – Turn the requirement for Transport layer Security (TLS) on or off.
 - **Idle client connection timeout** – Enter a time period for the idle client connection timeout.
 - **Secrets Manager secrets** – Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.
 - **IAM role** – Change the IAM role used to retrieve the secrets from Secrets Manager.
 - **IAM Authentication** – Require or disallow IAM authentication for connections to the proxy.
 - **VPC security group** – Add or remove VPC security groups for the proxy to use.
 - **Enable enhanced logging** – Enable or disable enhanced logging.
6. Choose **Modify**.

If you didn't find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The *target group* associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named `default`, which is created automatically along with the proxy.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.

To modify the settings for a proxy target group

1. On the **Proxies** page, go to the details page for a proxy.
2. For **Target groups**, choose the `default` link. Currently, all proxies have a single target group named `default`.
3. On the details page for the `default` target group, choose **Modify**.
4. Choose new settings for the properties that you can modify:
 - **Database** – Choose a different RDS DB instance or Aurora cluster.
 - **Connection pool maximum connections** – Adjust what percentage of the maximum available connections the proxy can use.
 - **Session pinning filters** – (Optional) Choose a session pinning filter. Doing this can help reduce performance issues due to insufficient transaction-level reuse for connections. Using this setting requires understanding of application behavior and the circumstances under which RDS Proxy pins a session to a database connection.
 - **Connection borrow timeout** – Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.
 - **Initialization query** – (Optional) Add an initialization query, or modify the current one. You can specify one or more SQL statements for the proxy to run when opening each new database connection. The setting is typically used with `SET` statements to make sure that each connection has identical settings such as time zone and character set. For multiple statements, use semicolons as the separator. You can also include multiple variables in a single `SET` statement, such as `SET x=1, y=2`. Initialization query is not currently supported for PostgreSQL.

You can't change certain properties, such as the target group identifier and the database engine.

5. Choose **Modify target group**.

AWS CLI

To modify a proxy using the AWS CLI, use the commands [modify-db-proxy](#), [modify-db-proxy-target-group](#), [deregister-db-proxy-targets](#), and [register-db-proxy-targets](#).

With the `modify-db-proxy` command, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

The following example shows how to rename an existing proxy.

```
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the `modify-db-proxy-target-group` command. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

The following example shows how to first check the `MaxIdleConnectionsPercent` setting for a proxy and then change it, using the target group.

```
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy

{
    "TargetGroups": [
        {
            "Status": "available",
            "UpdatedDate": "2019-11-30T16:49:30.342Z",
            "ConnectionPoolConfig": {
                "MaxIdleConnectionsPercent": 50,
                "ConnectionBorrowTimeout": 120,
                "MaxConnectionsPercent": 100,
                "SessionPinningFilters": []
            },
            "TargetGroupName": "default",
            "CreatedDate": "2019-11-30T16:49:27.940Z",
            "DBProxyName": "the-proxy",
            "IsDefault": true
        }
    ]
}

aws rds modify-db-proxy-target-group --db-proxy-name the-proxy --target-group-name default
--connection-pool-config '
{ "MaxIdleConnectionsPercent": 75 }'

{
    "DBProxyTargetGroup": {
        "Status": "available",
        "UpdatedDate": "2019-12-02T04:09:50.420Z",
        "ConnectionPoolConfig": {
            "MaxIdleConnectionsPercent": 75,
            "ConnectionBorrowTimeout": 120,
            "MaxConnectionsPercent": 100,
            "SessionPinningFilters": []
        }
    }
}
```

```

        "SessionPinningFilters": []
    },
    "TargetGroupName": "default",
    "CreatedDate": "2019-11-30T16:49:27.940Z",
    "DBProxyName": "the-proxy",
    "IsDefault": true
}
}

```

With the `deregister-db-proxy-targets` and `register-db-proxy-targets` commands, you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration, or all the DB instances in an Aurora cluster.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named `cluster-56-2020-02-25-1399`. The example shows how to change the proxy so that it can connect to a different cluster named `provisioned-cluster`.

When you work with an RDS DB instance, you specify the `--db-instance-identifier` option. When you work with an Aurora DB cluster, you specify the `--db-cluster-identifier` option instead.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.

```

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": [
        {
            "Endpoint": "instance-9814.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-9814"
        },
        {
            "Endpoint": "instance-8898.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-8898"
        },
        {
            "Endpoint": "instance-1018.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-1018"
        },
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "cluster-56-2020-02-25-1399"
        },
        {
            "Endpoint": "instance-4330.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-4330"
        }
    ]
}

aws rds deregister-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
cluster-56-2020-02-25-1399

```

```
aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": []
}

aws rds register-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
provisioned-cluster

{
    "DBProxyTargets": [
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "provisioned-cluster"
        },
        {
            "Endpoint": "gkldje.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,

        },
        {
            "Endpoint": "provisioned-1.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "provisioned-1"
        }
    ]
}
```

RDS API

To modify a proxy using the RDS API, you use the operations [ModifyDBProxy](#), [ModifyDBProxyTargetGroup](#), [DeregisterDBProxyTargets](#), and [RegisterDBProxyTargets](#) operations.

With [ModifyDBProxy](#), you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

With [ModifyDBProxyTargetGroup](#), you can modify connection-related settings or rename the target group. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

With [DeregisterDBProxyTargets](#) and [RegisterDBProxyTargets](#), you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration, or all the DB instances in an Aurora cluster.

Adding a new database user

In some cases, you might add a new database user to an RDS DB instance or Aurora cluster that's associated with a proxy. If so, add or repurpose a Secrets Manager secret to store the credentials for that user. To do this, choose one of the following options:

- Create a new Secrets Manager secret, using the procedure described in [Setting up database credentials in AWS Secrets Manager \(p. 296\)](#).
- Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
- If the new user takes the place of an existing one, update the credentials stored in the proxy's Secrets Manager secret for the existing user.

Changing the password for a database user

In some cases, you might change the password for a database user in an RDS DB instance or Aurora cluster that's associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

Configuring connection settings

To adjust RDS Proxy's connection pooling, you can modify the following settings:

- [IdleClientTimeout \(p. 311\)](#)
- [MaxConnectionsPercent \(p. 311\)](#)
- [MaxIdleConnectionsPercent \(p. 312\)](#)
- [ConnectionBorrowTimeout \(p. 312\)](#)

IdleClientTimeout

You can specify how long a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes).

A client connection is considered *idle* when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections. If you want the proxy to proactively remove stale connections, consider lowering the idle client connection timeout. If your workload establishes frequent connections with the proxy, consider raising the idle client connection timeout to save the cost of establishing connections.

This setting is represented by the **Idle client connection timeout** field in the RDS console and the `IdleClientTimeout` setting in the AWS CLI and the API. To learn how to change the value of the **Idle client connection timeout** field in the RDS console, see [AWS Management Console \(p. 306\)](#). To learn how to change the value of the `IdleClientTimeout` setting, see the CLI command [modify-db-proxy](#) or the API operation [ModifyDBProxy](#).

MaxConnectionsPercent

You can limit the number of connections that an RDS Proxy can establish with the database. You specify the limit as a percentage of the maximum connections available for your database. The proxy doesn't create all of these connections in advance. This setting reserves the right for the proxy to establish these connections as the workload needs them.

For example, suppose that you configured RDS Proxy to use 75 percent of the maximum connections for your database that supports a maximum of 1,000 concurrent connections. In that case, RDS Proxy can open up to 750 database connections.

This setting is represented by the **Connection pool maximum connections** field in the RDS console and the `MaxConnectionsPercent` setting in the AWS CLI and the API. To learn how to change the value of the **Connection pool maximum connections** field in the RDS console, see [AWS Management Console \(p. 306\)](#). To learn how to change the value of the `MaxConnectionsPercent` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

For information on database connection limits, see [Maximum connections to an Aurora MySQL DB instance](#) and [Maximum connections to an Aurora PostgreSQL DB instance](#).

MaxIdleConnectionsPercent

You can control the number of idle database connections that RDS Proxy can keep in the connection pool. RDS Proxy considers a database connection in its pool to be *idle* when there's been no activity on the connection for five minutes.

You specify the limit as a percentage of the maximum connections available for your database. The default value is 50 percent and the upper limit is the value of `MaxConnectionsPercent`. With a high value, the proxy leaves a high percentage of idle database connections open. With a low value, the proxy closes a high percentage of idle database connections. If your workloads are unpredictable, consider setting a high value for `MaxIdleConnectionsPercent` so that RDS Proxy can accommodate surges in activity without opening a lot of new database connections.

This setting is represented by the `MaxIdleConnectionsPercent` setting of `DBProxyTargetGroup` in the AWS CLI and the API. To learn how to change the value of the `MaxIdleConnectionsPercent` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

Note

RDS Proxy closes database connections some time after 24 hours when they are no longer in use. The proxy performs this action regardless of the value of the maximum idle connections setting.

For information on database connection limits, see [Maximum connections to an Aurora MySQL DB instance](#) and [Maximum connections to an Aurora PostgreSQL DB instance](#).

ConnectionBorrowTimeout

You can choose how long RDS Proxy waits for a database connection in the connection pool to become available for use before returning a timeout error. The default is 120 seconds. This setting applies when the number of connections is at the maximum, and so no connections are available in the connection pool. It also applies if no appropriate database instance is available to handle the request because, for example, a failover operation is in process. Using this setting, you can set the best wait period for your application without having to change the query timeout in your application code.

This setting is represented by the **Connection borrow timeout** field in the RDS console or the `ConnectionBorrowTimeout` setting of `DBProxyTargetGroup` in the AWS CLI or API. To learn how to change the value of the **Connection borrow timeout** field in the RDS console, see [AWS Management Console \(p. 306\)](#). To learn how to change the value of the `ConnectionBorrowTimeout` setting, see the CLI command [modify-db-proxy-target-group](#) or the API operation [ModifyDBProxyTargetGroup](#).

Avoiding pinning

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through `SET` or `SELECT` statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as *pinning*. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection

reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, if your application changes a session variable or configuration parameter, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

This rule doesn't apply to all parameters you can set. RDS Proxy tracks changes to the character set, collation, time zone, autocommit, current database, SQL mode, and `session_track_schema` settings. Thus RDS Proxy doesn't pin the session when you modify these. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings.

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning. You can do so by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.

However, for PostgreSQL setting a variable leads to session pinning.

- Apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn't affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the CloudWatch metric `DatabaseConnectionsCurrentlySessionPinned`. For information about this and other CloudWatch metrics, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 324\)](#).
- If you use `SET` statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.

For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding `SET` statements from your application code, so that they don't interfere with transaction-level multiplexing.

Important

For proxies associated with MySQL databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.
- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.
- Explicit MySQL statements `LOCK TABLE`, `LOCK TABLES`, or `FLUSH TABLES WITH READ LOCK` cause the proxy to pin the session.
- Setting a user variable or a system variable (with some exceptions) causes the proxy to pin the session. If this situation reduces your connection reuse too much, you can choose for `SET` operations not to cause pinning. For information about how to do so by setting the `SessionPinningFilters` property, see [Creating an RDS Proxy \(p. 299\)](#).
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.

- Calling the MySQL functions `ROW_COUNT`, `FOUND_ROWS`, and `LAST_INSERT_ID` sometimes causes pinning.

The exact circumstances where these functions cause pinning might differ between Aurora MySQL versions that are compatible with MySQL 5.6 and MySQL 5.7.

Calling MySQL stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Therefore, make sure that your application doesn't change session state inside stored routines and rely on that session state to persist across transactions. For example, if a stored procedure creates a temporary table that is intended to persist across transactions, that application currently isn't compatible with RDS Proxy.

For PostgreSQL, the following interactions also cause pinning:

- Using `SET` commands
- Using the PostgreSQL extended query protocol such as by using JDBC default settings
- Creating temporary sequences, tables, or views
- Declaring cursors
- Discarding the session state
- Listening on a notification channel
- Loading a library module such as `auto_explain`
- Manipulating sequences using functions such as `nextval` and `setval`
- Interacting with locks using functions such as `pg_advisory_lock` and `pg_try_advisory_lock`
- Using prepared statements, setting parameters, or resetting a parameter to its default

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the **Session pinning filters** option when creating the proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

For metrics about how often pinning occurs for a proxy, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 324\)](#).

Deleting an RDS Proxy

You can delete a proxy if you no longer need it. You might delete a proxy because the application that was using it is no longer relevant. Or you might delete a proxy if you take the DB instance or cluster associated with it out of service.

AWS Management Console

To delete a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Choose the proxy to delete from the list.
4. Choose **Delete Proxy**.

AWS CLI

To delete a DB proxy, use the AWS CLI command `delete-db-proxy`. To remove related associations, also use the `deregister-db-proxy-targets` command.

```
aws rds delete-db-proxy --name proxy_name
```

```
aws rds deregister-db-proxy-targets
--db-proxy-name proxy_name
[--target-group-name target_group_name]
[--target-ids comma_separated_list]      # or
[--db-instance-identifiers instance_id]      # or
[--db-cluster-identifiers cluster_id]
```

RDS API

To delete a DB proxy, call the Amazon RDS API function [DeleteDBProxy](#). To delete related items and associations, you also call the functions [DeleteDBProxyTargetGroup](#) and [DeregisterDBProxyTargets](#).

Working with Amazon RDS Proxy endpoints

Following, you can learn about endpoints for RDS Proxy and how to use them. By using endpoints, you can take advantage of the following capabilities:

- You can use multiple endpoints with a proxy to monitor and troubleshoot connections from different applications independently.
- You can use reader endpoints with Aurora DB clusters to improve read scalability and high availability for your query-intensive applications.
- You can use a cross-VPC endpoint to allow access to databases in one VPC from resources such as Amazon EC2 instances in a different VPC.

Topics

- [Overview of proxy endpoints \(p. 315\)](#)
- [Using reader endpoints with Aurora clusters \(p. 316\)](#)
- [Accessing Aurora and RDS databases across VPCs \(p. 319\)](#)
- [Creating a proxy endpoint \(p. 319\)](#)
- [Viewing proxy endpoints \(p. 321\)](#)
- [Modifying a proxy endpoint \(p. 322\)](#)
- [Deleting a proxy endpoint \(p. 323\)](#)
- [Limits for proxy endpoints \(p. 324\)](#)

Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with Aurora DB cluster and reader endpoints and RDS instance endpoints. If you aren't familiar with Aurora endpoints, find more information in [Amazon Aurora connection management \(p. 32\)](#).

By default, the endpoint that you connect to when you use RDS Proxy with an Aurora cluster has read/write capability. As a consequence, this endpoint sends all requests to the writer instance of the cluster, and all of those connections count against the `max_connections` value for the writer instance. If your proxy is associated with an Aurora DB cluster, you can create additional read/write or read-only endpoints for that proxy.

You can use a read-only endpoint with your proxy for read-only queries, the same way that you use the reader endpoint for an Aurora provisioned cluster. Doing so helps you to take advantage of the read scalability of an Aurora cluster with one or more reader DB instances. You can run more simultaneous

queries and make more simultaneous connections by using a read-only endpoint and adding more reader DB instances to your Aurora cluster as needed.

Tip

When you create a proxy for an Aurora cluster using the AWS Management Console, you can choose for RDS Proxy to automatically create a reader endpoint. For information about the benefits of a reader endpoint, see [Using reader endpoints with Aurora clusters \(p. 316\)](#).

For a proxy endpoint that you create, you can also associate the endpoint with a different virtual private cloud (VPC) than the proxy itself uses. By doing so, you can connect to the proxy from a different VPC, for example a VPC used by a different application within your organization.

For information about limits associated with proxy endpoints, see [Limits for proxy endpoints \(p. 324\)](#).

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy.

Each proxy endpoint has its own set of CloudWatch metrics. You can monitor the metrics for all endpoints of a proxy. You can also monitor metrics for a specific endpoint, or for all the read/write or read-only endpoints of a proxy. For more information, see [Monitoring RDS Proxy metrics with Amazon CloudWatch \(p. 324\)](#).

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

Using reader endpoints with Aurora clusters

You can create and connect to read-only endpoints called *reader endpoints* when you use RDS Proxy with Aurora clusters. These reader endpoints help to improve the read scalability of your query-intensive applications. Reader endpoints also help to improve the availability of your connections if a reader DB instance in your cluster becomes unavailable.

Note

When you specify that a new endpoint is read-only, RDS Proxy requires that the Aurora cluster has one or more reader DB instances. If you change the target of the proxy to an Aurora cluster containing only a single writer or a multi-writer Aurora cluster, any requests to the reader endpoint fail with an error. Requests also fail if the target of the proxy is an RDS instance instead of an Aurora cluster.

If an Aurora cluster has reader instances but those instances aren't available, RDS Proxy waits to send the request instead of returning an error immediately. If no reader instance becomes available within the connection borrow timeout period, the request fails with an error.

How reader endpoints help application availability

In some cases, one or more reader instances in your cluster might become unavailable. If so, connections that use a reader endpoint of a DB proxy can recover more quickly than ones that use the Aurora reader endpoint. RDS Proxy routes connections to only the available reader instances in the cluster. There isn't a delay due to DNS caching when an instance becomes unavailable.

If the connection is multiplexed, RDS Proxy directs subsequent queries to a different reader DB instance without any interruption to your application. During the automatic switchover to a new reader instance, RDS Proxy checks the replication lag of the old and new reader instances. RDS Proxy makes sure that the new reader instance is up to date with the same changes as the previous reader instance. That way, your application never sees stale data when RDS Proxy switches from one reader DB instance to another.

If the connection is pinned, the next query on the connection returns an error. However, your application can immediately reconnect to the same endpoint. RDS Proxy routes the connection to a different reader

DB instance that's in available state. When you manually reconnect, RDS Proxy doesn't check the replication lag between the old and new reader instances.

If your Aurora cluster doesn't have any available reader instances, RDS Proxy checks whether this condition is temporary or permanent. The behavior in each case is as follows:

- Suppose that your cluster has one or more reader DB instances, but none of them are in the Available state. For example, all reader instances might be rebooting or encountering problems. In that case, attempts to connect to a reader endpoint wait for a reader instance to become available. If no reader instance becomes available within the connection borrow timeout period, the connection attempt fails. If a reader instance does become available, the connection attempt succeeds.
- Suppose that your cluster has no reader DB instances. In that case, RDS Proxy returns an error immediately if you try to connect to a reader endpoint. To resolve this problem, add one or more reader instances to your cluster before you connect to the reader endpoint.

How reader endpoints help query scalability

Reader endpoints for a proxy help with Aurora query scalability in the following ways:

- As you add reader instances to your Aurora cluster, RDS Proxy can route new connections to any reader endpoints to the different reader instances. That way, queries performed using one reader endpoint connection don't slow down queries performed using another reader endpoint connection. The queries run on separate DB instances. Each DB instance has its own compute resources, buffer cache, and so on.
- Where practical, RDS Proxy uses the same reader DB instance for all the queries issued using a particular reader endpoint connection. That way, a set of related queries on the same tables can take advantage of caching, plan optimization, and so on, on a particular DB instance.
- If a reader DB instance becomes unavailable, the effect on your application depends on whether the session is multiplexed or pinned. If the session is multiplexed, RDS Proxy routes any subsequent queries to a different reader DB instance without any action on your part. If the session is pinned, your application gets an error and must reconnect. You can reconnect to the reader endpoint immediately and RDS Proxy routes the connection to an available reader DB instance. For more information about multiplexing and pinning for proxy sessions, see [Overview of RDS Proxy concepts \(p. 291\)](#).
- The more reader DB instances you have in the cluster, the more simultaneous connections you can make using reader endpoints. For example, suppose that your cluster has four reader DB instances, each configured to allow 200 simultaneous connections. Suppose that your proxy is configured to use 50% of the maximum connections. Here, the maximum number of connections that you can make through the reader endpoints in the proxy is 100 (50% of 200) for reader 1. It's also 100 for reader 2, and so on, for a total of 400. If you double the number of reader DB instances in the cluster to eight, the maximum number of connections through the reader endpoints also doubles to 800.

Examples of using reader endpoints

The following Linux example shows how you can confirm that you're connected to an Aurora MySQL cluster through a reader endpoint. The `innodb_read_only` configuration setting is enabled. Attempts to perform write operations such as `CREATE DATABASE` statements fail with an error. And you can confirm that you're connected to a reader DB instance by checking the DB instance name using the `aurora_server_id` variable.

Tip

Don't rely only on checking the DB instance name to determine whether the connection is read/write or read-only. Remember that DB instances in an Aurora cluster can change roles between writer and reader when failovers happen.

```
$ mysql -h endpoint-demo-reader.endpoint.proxy-demo.us-east-1.rds.amazonaws.com -u admin -p  
...
```

```

mysql> select @@innodb_read_only;
+-----+
| @@innodb_read_only |
+-----+
| 1 |
+-----+
mysql> create database shouldnt_work;
ERROR 1290 (HY000): The MySQL server is running with the --read-only option so it cannot
execute this statement

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| proxy-reader-endpoint-demo-instance-3 |
+-----+

```

The following example shows how your connection to a proxy reader endpoint can keep working even when the reader DB instance is deleted. In this example, the Aurora cluster has two reader instances, `instance-5507` and `instance-7448`. The connection to the reader endpoint begins using one of the reader instances. During the example, this reader instance is deleted by a `delete-db-instance` command. RDS Proxy switches to a different reader instance for subsequent queries.

```

$ mysql -h reader-demo.endpoint.proxy-demo.us-east-1.rds.amazonaws.com
-u my_user -p
...
mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-5507 |
+-----+

mysql> select @@innodb_read_only;
+-----+
| @@innodb_read_only |
+-----+
| 1 |
+-----+

mysql> select count(*) from information_schema.tables;
+-----+
| count(*) |
+-----+
| 328 |
+-----+

```

While the `mysql` session is still running, the following command deletes the reader instance that the reader endpoint is connected to.

```
aws rds delete-db-instance --db-instance-identifier instance-5507 --skip-final-snapshot
```

Queries in the `mysql` session continue working without the need to reconnect. RDS Proxy automatically switches to a different reader DB instance.

```

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-7448 |
+-----+

```

```
mysql> select count(*) from information_schema.TABLES;
+-----+
| count(*) |
+-----+
|      328 |
+-----+
```

Accessing Aurora and RDS databases across VPCs

By default, the components of your RDS and Aurora technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Amazon RDS DB instance or an Aurora DB cluster. In this case, the application server and database must both be within the same VPC.

With RDS Proxy, you can set up access to an Aurora cluster or RDS instance in one VPC from resources such as EC2 instances in another VPC. For example, your organization might have multiple applications that access the same database resources. Each application might be in its own VPC.

To enable cross-VPC access, you create a new endpoint for the proxy. If you aren't familiar with creating proxy endpoints, see [Working with Amazon RDS Proxy endpoints \(p. 315\)](#) for details. The proxy itself resides in the same VPC as the Aurora DB cluster or RDS instance. However, the cross-VPC endpoint resides in the other VPC, along with the other resources such as the EC2 instances. The cross-VPC endpoint is associated with subnets and security groups from the same VPC as the EC2 and other resources. These associations let you connect to the endpoint from the applications that otherwise can't access the database due to the VPC restrictions.

The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for Aurora and RDS work. Each VPC should have its own associated network resources such as an Internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult [Getting started with Amazon Aurora \(p. 89\)](#) for the steps to set up another VPC to use Aurora successfully. You can also examine your existing VPC in the Amazon EC2 console to see what kinds of resources to connect together.
2. Create a DB proxy associated with the Aurora DB cluster or RDS instance that you want to connect to. Follow the procedure in [Creating an RDS Proxy \(p. 299\)](#).
3. On the **Details** page for your proxy in the RDS console, under the **Proxy endpoints** section, choose **Create endpoint**. Follow the procedure in [Creating a proxy endpoint \(p. 319\)](#).
4. Choose whether to make the cross-VPC endpoint read/write or read-only.
5. Instead of accepting the default of the same VPC as the Aurora DB cluster or RDS instance, choose a different VPC. This VPC must be in the same AWS Region as the VPC where the proxy resides.
6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Aurora DB cluster or RDS instance, make new selections. Make these based on the subnets and security groups from the VPC that you chose.
7. You don't need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in.
8. Wait for the new endpoint to reach the **Available** state.
9. Make a note of the full endpoint name. This is the value ending in `Region_name.rds.amazonaws.com` that you supply as part of the connection string for your database application.
10. Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then you can log into the EC2 instance and run the `mysql` or `psql` commands to connect by using the endpoint value in your connection string.

Creating a proxy endpoint

Console

To create a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Click the name of the proxy that you want to create a new endpoint for.

The details page for that proxy appears.

4. In the **Proxy endpoints** section, choose **Create proxy endpoint**.
- The **Create proxy endpoint** window appears.
5. For **Proxy endpoint name**, enter a descriptive name of your choice.
 6. For **Target role**, choose whether to make the endpoint read/write or read-only.

Connections that use a read/write endpoint can perform any kind of operation: data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the Aurora cluster. You can use read/write endpoints for general database operations when you only use a single endpoint in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.

Connections that use a read-only endpoint can only perform queries. When there are multiple reader instances in the Aurora cluster, RDS Proxy can use a different reader instance for each connection to the endpoint. That way, a query-intensive application can take advantage of Aurora's clustering capability. You can add more query capacity to the cluster by adding more reader DB instances. These read-only connections don't impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don't slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default if you plan to access the endpoint from the same EC2 instances or other resources where you normally access the proxy or its associated database. If you want to set up cross-VPC access for this proxy, choose a VPC other than the default. For more information about cross-VPC access, see [Accessing Aurora and RDS databases across VPCs \(p. 319\)](#).
8. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. If you want to restrict access to the endpoint so that only a portion of the address range of the VPC can connect to it, remove one or more subnets from the set of choices.
9. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, you can leave the default choice.

If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console afterward.

10. Choose **Create proxy endpoint**.

AWS CLI

To create a proxy endpoint, use the AWS CLI `create-db-proxy-endpoint` command.

Include the following required parameters:

- `--db-proxy-name value`
- `--db-proxy-endpoint-name value`

- `--vpc-subnet-ids` *list_of_ids*. Separate the subnet IDs with spaces. You don't specify the ID of the VPC itself.

You can also include the following optional parameters:

- `--target-role` { `READ_WRITE` | `READ_ONLY` }. This parameter defaults to `READ_WRITE`. The `READ_ONLY` value only has an effect on Aurora provisioned clusters that contain one or more reader DB instances. When the proxy is associated with an RDS instance or with an Aurora cluster that only contains a writer DB instance, you can't specify `READ_ONLY`. For more information about the intended use of read-only endpoints with Aurora clusters, see [Using reader endpoints with Aurora clusters \(p. 316\)](#).
- `--vpc-security-group-ids` *value*. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.

Example

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds create-db-proxy-endpoint \
--db-proxy-name my-proxy \
--db-proxy-endpoint-name my-endpoint \
--vpc-subnet-ids subnet_id subnet_id subnet_id ... \
--target-role READ_ONLY \
--vpc-security-group-ids security_group_id ]
```

For Windows:

```
aws rds create-db-proxy-endpoint ^
--db-proxy-name my-proxy ^
--db-proxy-endpoint-name my-endpoint ^
--vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
--target-role READ_ONLY ^
--vpc-security-group-ids security_group_id
```

RDS API

To create a proxy endpoint, use the RDS API [CreateProxyEndpoint](#) action.

Viewing proxy endpoints

Console

To view the details for a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to view. Click its name to view the details page.
5. Examine the parameters whose values you're interested in. You can check properties such as the following:

- Whether the endpoint is read/write or read-only.
- The endpoint address that you use in a database connection string.
- The VPC, subnets, and security groups associated with the endpoint.

AWS CLI

To view one or more DB proxy endpoints, use the AWS CLI [describe-db-proxy-endpoints](#) command.

You can include the following optional parameters:

- `--db-proxy-endpoint-name`
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-proxy-endpoints \
--db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds describe-db-proxy-endpoints ^
--db-proxy-endpoint-name my-endpoint
```

RDS API

To describe one or more proxy endpoints, use the RDS API [DescribeDBProxyEndpoints](#) operation.

Modifying a proxy endpoint

Console

To modify one or more proxy endpoints

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.
5. On the proxy details page, under the **Proxy endpoints** section, choose **Edit**. Or on the proxy endpoint details page, for **Actions**, choose **Edit**.
6. Change the values of the parameters that you want to modify.
7. Choose **Save changes**.

AWS CLI

To modify a DB proxy endpoint, use the AWS CLI [modify-db-proxy-endpoint](#) command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.

The following example renames the `my-endpoint` proxy endpoint to `new-endpoint-name`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-proxy-endpoint \
--db-proxy-endpoint-name my-endpoint \
--new-db-proxy-endpoint-name new-endpoint-name
```

For Windows:

```
aws rds modify-db-proxy-endpoint ^
--db-proxy-endpoint-name my-endpoint ^
--new-db-proxy-endpoint-name new-endpoint-name
```

RDS API

To modify a proxy endpoint, use the RDS API [ModifyDBProxyEndpoint](#) operation.

Deleting a proxy endpoint

You can delete an endpoint for your proxy using the console as described following.

Note

You can't delete the default endpoint that RDS Proxy automatically creates for each proxy. When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

Console

To delete a proxy endpoint using the AWS Management Console

1. In the navigation pane, choose **Proxies**.
2. In the list, choose the proxy whose endpoint you want to endpoint. Click the proxy name to view its details page.
3. In the **Proxy endpoints** section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.
4. On the proxy details page, under the **Proxy endpoints** section, choose **Delete**. Or on the proxy endpoint details page, for **Actions**, choose **Delete**.

AWS CLI

To delete a proxy endpoint, run the `delete-db-proxy-endpoint` command with the following required parameters:

- `--db-proxy-endpoint-name`

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds delete-db-proxy-endpoint \
--db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds delete-db-proxy-endpoint ^
--db-proxy-endpoint-name my-endpoint
```

RDS API

To delete a proxy endpoint with the RDS API, run the [DeleteDBProxyEndpoint](#) operation. Specify the name of the proxy endpoint for the `DBProxyEndpointName` parameter.

Limits for proxy endpoints

Each proxy has a default endpoint that you can modify but not create or delete.

The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.

When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint. You can't choose specific instances the way that you can with Aurora custom endpoints.

Reader endpoints aren't available for Aurora multi-writer clusters.

You can connect to proxy endpoints that you create using the SSL modes `REQUIRED` and `VERIFY_CA`. You can't connect to an endpoint that you create using the SSL mode `VERIFY_IDENTITY`.

Monitoring RDS Proxy metrics with Amazon CloudWatch

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose **Metrics**, then choose **RDS**, and choose **Per-Proxy Metrics**. For more information, see [Using Amazon CloudWatch metrics](#) in the Amazon CloudWatch User Guide.

Note

RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy.

A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances.

Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy.

All RDS Proxy metrics are in the group `proxy`.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see [Working with Amazon RDS Proxy endpoints \(p. 315\)](#).

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the `ProxyName` dimension set, you can analyze all the traffic for a particular proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on

the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: `ProxyName`
- Dimension set 2: `ProxyName, EndpointName`
- Dimension set 3: `ProxyName, TargetGroup, Target`
- Dimension set 4: `ProxyName, TargetGroup, TargetRole`

Metric	Description	Valid period	CloudWatch dimension set
AvailabilityPercentage	The percentage of time for which the target group was available in the role indicated by the dimension. This metric is reported every minute. The most useful statistic for this metric is <code>Average</code> .	1 minute	Dimension set 4 (p. 325)
ClientConnections	The current number of client connections. This metric is reported every minute. The most useful statistic for this metric is <code>Sum</code> .	1 minute	Dimension set 1 (p. 325) , Dimension set 2 (p. 325)
ClientConnectionsClosed	The number of client connections closed. The most useful statistic for this metric is <code>Sum</code> .	1 minute and above	Dimension set 1 (p. 325) , Dimension set 2 (p. 325)
ClientConnectionsNotEncrypted	The current number of client connections without Transport Layer Security (TLS). This metric is reported every minute. The most useful statistic for this metric is <code>Sum</code> .	1 minute and above	Dimension set 1 (p. 325) , Dimension set 2 (p. 325)
ClientConnectionsReceived	The number of client connection requests received. The most useful statistic for this metric is <code>Sum</code> .	1 minute and above	Dimension set 1 (p. 325) , Dimension set 2 (p. 325)
ClientConnectionsRejected	The number of client connection attempts that failed due to misconfigured authentication or TLS. The most useful statistic for this metric is <code>Sum</code> .	1 minute and above	Dimension set 1 (p. 325) , Dimension set 2 (p. 325)

Metric	Description	Valid period	CloudWatch dimension set
ClientConnectionsSet	The number of client connections successfully established with any authentication mechanism with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 325), Dimension set 2 (p. 325)
ClientConnectionsTLS	The current number of client connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 325), Dimension set 2 (p. 325)
DatabaseConnectionRequests	The number of requests to create a database connection. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 325), Dimension set 3 (p. 325), Dimension set 4 (p. 325)
DatabaseConnectionRequestsTLS	The number of requests to create a database connection with TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 325), Dimension set 3 (p. 325), Dimension set 4 (p. 325)
DatabaseConnections	The current number of database connections. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 325), Dimension set 3 (p. 325), Dimension set 4 (p. 325)
DatabaseConnectionsLatency	The latency in microseconds that it takes for the proxy being monitored to get a database connection. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1 (p. 325), Dimension set 2 (p. 325)
DatabaseConnectionsPending	The current number of database connections in the borrow state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 325), Dimension set 3 (p. 325), Dimension set 4 (p. 325)

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnections	The current number of database connections in a transaction. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 325), Dimension set 3 (p. 325), Dimension set 4 (p. 325)
DatabaseConnections	The current session of database connections currently pinned because of operations in client requests that change session state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 325), Dimension set 3 (p. 325), Dimension set 4 (p. 325)
DatabaseConnections	The number of database connection requests that failed. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 325), Dimension set 3 (p. 325), Dimension set 4 (p. 325)
DatabaseConnections	The number of database connections successfully established with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 325), Dimension set 3 (p. 325), Dimension set 4 (p. 325)
DatabaseConnections	The current number of database connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 325), Dimension set 3 (p. 325), Dimension set 4 (p. 325)
MaxDatabaseConnections	The maximum number of database connections allowed. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 325), Dimension set 3 (p. 325), Dimension set 4 (p. 325)

Metric	Description	Valid period	CloudWatch dimension set
QueryDatabaseResponseLatency	The time in microseconds that the database took to respond to the query. The most useful statistic for this metric is Average .	1 minute and above	Dimension set 1 (p. 325) , Dimension set 2 (p. 325) , Dimension set 3 (p. 325) , Dimension set 4 (p. 325)
QueryRequests	The number of queries received. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum .	1 minute and above	Dimension set 1 (p. 325) , Dimension set 2 (p. 325)
QueryRequestsNoTLS	The number of queries received from non-TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum .	1 minute and above	Dimension set 1 (p. 325) , Dimension set 2 (p. 325)
QueryRequestsTLS	The number of queries received from TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum .	1 minute and above	Dimension set 1 (p. 325) , Dimension set 2 (p. 325)
QueryResponseLatency	The time in microseconds between getting a query request and the proxy responding to it. The most useful statistic for this metric is Average .	1 minute and above	Dimension set 1 (p. 325) , Dimension set 2 (p. 325)

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the **Log groups** page.

Important

These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change. In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name `default` for requests using the default endpoint of a proxy.

Working with RDS Proxy events

An *event* indicates a change in an environment. This can be an AWS environment or a service or application from a software as a service (SaaS) partner. Or it can be one of your own custom applications or services. For example, Amazon Aurora generates an event when you create or modify an RDS Proxy. Amazon Aurora delivers events to CloudWatch Events and Amazon EventBridge in near-real time. Following, you can find a list of RDS Proxy events that you can subscribe to and an example of an RDS Proxy event.

For more information about working with events, see the following:

- For instructions on how to view events by using the AWS Management Console, AWS CLI, or RDS API, see [Viewing Amazon RDS events \(p. 674\)](#).
- To learn how to configure Amazon Aurora to send events to EventBridge, see [Creating a rule that triggers on an Amazon Aurora event \(p. 692\)](#).

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

Category	RDS event ID	Description
Configuration change	RDS-EVENT-0204	RDS modified the DB proxy (RDS Proxy).
Configuration change	RDS-EVENT-0207	RDS modified the endpoint of the DB proxy (RDS Proxy).
Configuration change	RDS-EVENT-0213	RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy (RDS Proxy).
Configuration change	RDS-EVENT-0214	RDS detected the deletion of the DB instance and automatically removed it from the target group of the DB proxy (RDS Proxy).
Configuration change	RDS-EVENT-XXXX	RDS detected the deletion of the DB cluster and automatically removed it from the target group of the DB proxy (RDS Proxy).
Creation	RDS-EVENT-0203	RDS created the DB proxy (RDS Proxy).
Creation	RDS-EVENT-0206	RDS created the endpoint for the DB proxy (RDS Proxy).
Deletion	RDS-EVENT-0205	RDS deleted the DB proxy (RDS Proxy).
Deletion	RDS-EVENT-0208	RDS deleted the endpoint of DB proxy (RDS Proxy).

The following is an example of an RDS Proxy event in JSON format. The event shows that RDS modified the endpoint named `my-endpoint` of the RDS Proxy named `my-rds-proxy`. The event ID is RDS-EVENT-0207.

```
{  
  "version": "0",  
  "eventVersion": "1.0",

```

RDS Proxy command-line examples

To see how combinations of connection commands and SQL statements interact with RDS Proxy, look at the following examples.

Examples

- [Preserving Connections to a MySQL Database Across a Failover](#)
- [Adjusting the max_connections Setting for an Aurora DB Cluster](#)

Example Preserving connections to a MySQL database across a failover

This MySQL example demonstrates how open connections continue working during a failover, for example when you reboot a database or it becomes unavailable due to a problem. This example uses a proxy named `the-proxy` and an Aurora DB cluster with DB instances `instance-8898` and `instance-9814`. When you run the `failover-db-cluster` command from the Linux command line, the writer instance that the proxy is connected to changes to a different DB instance. You can see that the DB instance associated with the proxy changes while the connection remains open.

```

$ mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
Enter password:
...
mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-9814      |
+-----+
1 row in set (0.01 sec)

mysql>
[1]+  Stopped                  mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -
u admin_user -p
$ # Initially, instance-9814 is the writer.
$ aws rds failover-db-cluster --db-cluster-identifier cluster-56-2019-11-14-1399
JSON output
$ # After a short time, the console shows that the failover operation is complete.

```

```
$ # Now instance-8898 is the writer.
$ fg
mysql -h the-proxy.proxy-demo.us.us-east-1.rds.amazonaws.com -u admin_user -p

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-8898      |
+-----+
1 row in set (0.01 sec)

mysql>
[1]+  Stopped                  mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -
u admin_user -p
$ aws rds failover-db-cluster --db-cluster-identifier cluster-56-2019-11-14-1399
JSON output
$ # After a short time, the console shows that the failover operation is complete.
$ # Now instance-9814 is the writer again.
$ fg
mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p

mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-9814      |
+-----+
1 row in set (0.01 sec)
+-----+-----+
| Variable_name | Value      |
+-----+-----+
| hostname     | ip-10-1-3-178 |
+-----+-----+
1 row in set (0.02 sec)
```

Example Adjusting the max_connections setting for an Aurora DB cluster

This example demonstrates how you can adjust the max_connections setting for an Aurora MySQL DB cluster. To do so, you create your own DB cluster parameter group based on the default parameter settings for clusters that are compatible with MySQL 5.6 or 5.7. You specify a value for the max_connections setting, overriding the formula that sets the default value. You associate the DB cluster parameter group with your DB cluster.

```
export REGION=us-east-1
export CLUSTER_PARAM_GROUP=rds-proxy-mysql-56-max-connections-demo
export CLUSTER_NAME=rds-proxy-mysql-56

aws rds create-db-parameter-group --region $REGION \
--db-parameter-group-family aurora5.6 \
--db-parameter-group-name $CLUSTER_PARAM_GROUP \
--description "Aurora MySQL 5.6 cluster parameter group for RDS Proxy demo."

aws rds modify-db-cluster --region $REGION \
--db-cluster-identifier $CLUSTER_NAME \
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP

echo "New cluster param group is assigned to cluster:"
aws rds describe-db-clusters --region $REGION \
--db-cluster-identifier $CLUSTER_NAME \
--query '*[*].{DBClusterParameterGroup:DBClusterParameterGroup}'

echo "Current value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
```

```
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
--query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
--output text | grep "max_connections"

echo -n "Enter number for max_connections setting: "
read answer

aws rds modify-db-cluster-parameter-group --region $REGION --db-cluster-parameter-group-
name $CLUSTER_PARAM_GROUP \
--parameters "ParameterName=max_connections,ParameterValue=$
$answer,ApplyMethod=immediate"

echo "Updated value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
--query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
--output text | grep "max_connections"
```

Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy. For more information about proxy endpoints, see [Working with Amazon RDS Proxy endpoints \(p. 315\)](#).

Topics

- [Verifying connectivity for a proxy \(p. 332\)](#)
- [Common issues and solutions \(p. 333\)](#)

Verifying connectivity for a proxy

You can use the following commands to verify that all components of the connection mechanism can communicate with the other components.

Examine the proxy itself using the `describe-db-proxies` command. Also examine the associated target group using the `describe-db-proxy-target-groups`. Check that the details of the targets match the RDS DB instance or Aurora DB cluster that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the `describe-db-proxy-targets` command. Use a command such as the following.

```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the `describe-db-proxy-targets` command includes a `TargetHealth` field. You can examine the fields `State`, `Reason`, and `Description` inside `TargetHealth` to check if the proxy can communicate with the underlying DB instance.

- A `State` value of `AVAILABLE` indicates that the proxy can connect to the DB instance.

- A State value of UNAVAILABLE indicates a temporary or permanent connection problem. In this case, examine the Reason and Description fields. For example, if Reason has a value of PENDING_PROXY_CAPACITY, try connecting again after the proxy finishes its scaling operation. If Reason has a value of UNREACHABLE, CONNECTION_FAILED, or AUTH_FAILURE, use the explanation from the Description field to help you diagnose the issue.
- The State field might have a value of REGISTERING for a brief time before changing to AVAILABLE or UNAVAILABLE.

If the following Netcat command (nc) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```
nc -zx MySQL_proxy_endpoint 3306
nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the RDS DB instance or Aurora DB cluster that the proxy connects to.

```
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```
aws secretsmanager list-secrets
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the SecretString field displayed by get-secret-value is encoded as a JSON string that includes username and password fields. The following example shows the format of the SecretString field.

```
{
    "ARN": "some_arn",
    "Name": "some_name",
    "VersionId": "some_version_id",
    "SecretString": '{"username":"some_username","password":"some_password"}',
    "VersionStages": [ "some_stage" ],
    "CreatedDate": some_timestamp
}
```

Common issues and solutions

For possible causes and solutions to some common problems that you might encounter using RDS Proxy, see the following.

You might encounter the following issues while creating a new proxy or connecting to a proxy.

Error	Causes or workarounds
403: The security token included in the request is invalid	Select an existing IAM role instead of choosing to create a new one.

You might encounter the following issues while connecting to a MySQL proxy.

Error	Causes or workarounds
ERROR 1040 (HY000): Connections rate limit exceeded (<i>limit_value</i>)	The rate of connection requests from the client to the proxy has exceeded the limit.
ERROR 1040 (HY000): IAM authentication rate limit exceeded	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.
ERROR 1040 (HY000): Number simultaneous connections exceeded (<i>limit_value</i>)	The number of simultaneous connection requests from the client to the proxy exceeded the limit.
ERROR 1045 (28000): Access denied for user ' <i>DB_USER</i> '@'%' (using password: YES)	<p>Some possible reasons include the following:</p> <ul style="list-style-type: none"> The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret.
ERROR 1105 (HY000): Unknown error	An unknown error occurred.
ERROR 1231 (42000): Variable 'character_set_client' can't be set to the value of <i>value</i>	The value set for the <code>character_set_client</code> parameter is not valid. For example, the value <code>ucs2</code> is not valid because it can crash the MySQL server.
ERROR 3159 (HY000): This RDS Proxy requires TLS connections.	<p>You enabled the setting Require Transport Layer Security in the proxy but your connection included the parameter <code>ssl-mode=DISABLED</code> in the MySQL client. Do either of the following:</p> <ul style="list-style-type: none"> Disable the setting Require Transport Layer Security for the proxy. Connect to the database using the minimum setting of <code>ssl-mode=REQUIRED</code> in the MySQL client.

Some possible reasons include the following:</p> <ul style="list-style-type: none"> SSL is required but the server doesn't support it. An internal server error occurred. A bad handshake occurred.
ERROR 9501 (HY000): Timed-out waiting to	The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:

Error	Causes or workarounds
acquire database connection	<ul style="list-style-type: none"> The proxy is unable to establish a database connection because the maximum connections have been reached The proxy is unable to establish a database connection because the database is unavailable.

You might encounter the following issues while connecting to a PostgreSQL proxy.

Error	Cause	Solution
IAM authentication is allowed only with SSL connections.	The user tried to connect to the database using IAM authentication with the setting <code>sslmode=disable</code> in the PostgreSQL client.	The user needs to connect to the database using the minimum setting of <code>sslmode=require</code> in the PostgreSQL client. For more information, see the PostgreSQL SSL support documentation.
This RDS Proxy requires TLS connections.	The user enabled the option Require Transport Layer Security but tried to connect with <code>sslmode=disable</code> in the PostgreSQL client.	To fix this error, do one of the following: <ul style="list-style-type: none"> Disable the proxy's Require Transport Layer Security option. Connect to the database using the minimum setting of <code>sslmode=allow</code> in the PostgreSQL client.
IAM authentication failed for user <code>user_name</code> . Check the IAM token for this user and try again.	This error might be due to the following reasons: <ul style="list-style-type: none"> The client supplied the incorrect IAM user name. The client supplied an incorrect IAM authorization token for the user. The client is using an IAM policy that does not have the necessary permissions. The client supplied an expired IAM authorization token for the user. 	To fix this error, do the following: <ol style="list-style-type: none"> Confirm that the provided IAM user exists. Confirm that the IAM authorization token belongs to the provided IAM user. Confirm that the IAM policy has adequate permissions for RDS. Check the validity of the IAM authorization token used.
This RDS proxy has no credentials for the role <code>role_name</code> . Check the credentials for this role and try again.	There is no Secrets Manager secret for this role.	Add a Secrets Manager secret for this role.
RDS supports only IAM or MD5 authentication.	The database client being used to connect to the proxy is using an authentication mechanism not currently supported by the proxy, such as SCRAM-SHA-256.	If you're not using IAM authentication, use the MD5 password authentication only.

Error	Cause	Solution
A user name is missing from the connection startup packet. Provide a user name for this connection.	The database client being used to connect to the proxy isn't sending a user name when trying to establish a connection.	Make sure to define a user name when setting up a connection to the proxy using the PostgreSQL client of your choice.
Feature not supported: RDS Proxy supports only version 3.0 of the PostgreSQL messaging protocol.	The PostgreSQL client used to connect to the proxy uses a protocol older than 3.0.	Use a newer PostgreSQL client that supports the 3.0 messaging protocol. If you're using the PostgreSQL <code>psql</code> CLI, use a version greater than or equal to 7.4.
Feature not supported: RDS Proxy currently doesn't support streaming replication mode.	The PostgreSQL client used to connect to the proxy is trying to use the streaming replication mode, which isn't currently supported by RDS Proxy.	Turn off the streaming replication mode in the PostgreSQL client being used to connect.
Feature not supported: RDS Proxy currently doesn't support the option <code>option_name</code> .	Through the startup message, the PostgreSQL client used to connect to the proxy is requesting an option that isn't currently supported by RDS Proxy.	Turn off the option being shown as not supported from the message above in the PostgreSQL client being used to connect.
The IAM authentication failed because of too many competing requests.	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.	Reduce the rate in which connections using IAM authentication from a PostgreSQL client are established.
The maximum number of client connections to the proxy exceeded <code>number_value</code> .	The number of simultaneous connection requests from the client to the proxy exceeded the limit.	Reduce the number of active connections from PostgreSQL clients to this RDS proxy.
Rate of connection to proxy exceeded <code>number_value</code> .	The rate of connection requests from the client to the proxy has exceeded the limit.	Reduce the rate in which connections from a PostgreSQL client are established.
The password that was provided for the role <code>role_name</code> is wrong.	The password for this role doesn't match the Secrets Manager secret.	Check the secret for this role in Secrets Manager to see if the password is the same as what's being used in your PostgreSQL client.
The IAM authentication failed for the role <code>role_name</code> . Check the IAM token for this role and try again.	There is a problem with the IAM token used for IAM authentication.	Generate a new authentication token and use it in a new connection.
IAM is allowed only with SSL connections.	A client tried to connect using IAM authentication, but SSL wasn't enabled.	Enable SSL in the PostgreSQL client.

Error	Cause	Solution
Unknown error.	An unknown error occurred.	Reach out to AWS Support to investigate the issue.
Timed-out waiting to acquire database connection.	The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following: <ul style="list-style-type: none"> The proxy can't establish a database connection because the maximum connections have been reached. The proxy can't establish a database connection because the database is unavailable. 	Possible solutions are the following: <ul style="list-style-type: none"> Check the target of the RDS DB instance or Aurora DB cluster status to see if it's unavailable. Check if there are long-running transactions and/or queries being executed. They can use database connections from the connection pool for a long time.
Request returned an error: <i>database_error</i> .	The database connection established from the proxy returned an error.	The solution depends on the specific database error. One example is: Request returned an error: database "your-database-name" does not exist. This means the specified database name, or the user name used as a database name (in case a database name hasn't been specified), doesn't exist in the database server.

Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. Doing so helps you to create groups of related resources, including a proxy that can connect to a newly created Amazon RDS DB instance or Aurora DB cluster. RDS Proxy support in AWS CloudFormation involves two new registry types: `DBProxy` and `DBProxyTargetGroup`.

The following listing shows a sample AWS CloudFormation template for RDS Proxy.

```

Resources:
  DBProxy:
    Type: AWS::RDS::DBProxy
    Properties:
      DBProxyName: CanaryProxy
      EngineFamily: MYSQL
      RoleArn:
        Fn::ImportValue: SecretReaderRoleArn
      Auth:
        - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
      VpcSubnetIds:
        Fn::Split: [",", "Fn::ImportValue": SubnetIds]

  ProxyTargetGroup:
    Type: AWS::RDS::DBProxyTargetGroup
    Properties:
      DBProxyName: CanaryProxy

```

```
TargetGroupName: default
DBInstanceIdentifiers:
  - Fn::ImportValue: DBInstanceName
DependsOn: DBProxy
```

For more information about the Amazon RDS and Aurora resources that you can create using AWS CloudFormation, see [RDS resource type reference](#).

Working with DB parameter groups and DB cluster parameter groups

Database parameters specify how the database is configured. For example, database parameters can specify the amount of resources, such as memory, to allocate to a database.

You manage your database configuration by associating your DB instances and Aurora DB clusters with parameter groups. Amazon RDS defines parameter groups with default settings.

Important

You can define your own parameter groups with customized settings. Then you can modify your DB instances and Aurora clusters to use your own parameter groups.

For information about modifying a DB cluster or DB instance, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

A *DB parameter group* acts as a container for engine configuration values that are applied to one or more DB instances. DB parameter groups apply to DB instances in both Amazon RDS and Aurora. These configuration settings apply to properties that can vary among the DB instances within an Aurora cluster, such as the sizes for memory buffers.

A *DB cluster parameter group* acts as a container for engine configuration values that are applied to every DB instance in an Aurora DB cluster. For example, the Aurora shared storage model requires that every DB instance in an Aurora cluster use the same setting for parameters such as `innodb_file_per_table`. Thus, parameters that affect the physical storage layout are part of the cluster parameter group. The DB cluster parameter group also includes default values for all the instance-level parameters

If you create a DB instance without specifying a DB parameter group, the DB instance uses a default DB parameter group. Likewise, if you create an Aurora DB cluster without specifying a DB cluster parameter group, the DB cluster uses a default DB cluster parameter group. Each default parameter group contains database engine defaults and Amazon RDS system defaults based on the engine, compute class, and allocated storage of the instance. You can't modify the parameter settings of a default parameter group. Instead, you create your own parameter group where you choose your own parameter settings. Not all DB engine parameters can be changed in a parameter group that you create.

If you want to use your own parameter group, you create a new parameter group and modify the parameters that you want to. You then modify your DB instance or DB cluster to use the new parameter group. If you update parameters within a DB parameter group, the changes apply to all DB instances that are associated with that parameter group. Likewise, if you update parameters within a DB cluster parameter group, the changes apply to all Aurora clusters that are associated with that DB cluster parameter group.

You can copy an existing DB parameter group with the AWS CLI [copy-db-parameter-group](#) command. You can copy an existing DB cluster parameter group with the AWS CLI [copy-db-cluster-parameter-group](#) command. Copying a parameter group can be convenient when you want to include most of an existing parameter group's custom parameters and values in a new parameter group.

Here are some important points about working with parameters in a parameter group:

- Database parameters are either *static* or *dynamic*. When you change a static parameter and save the DB parameter group, the parameter change takes effect after you manually reboot the DB instance. You can reboot a DB instance using the RDS console, by calling the `reboot-db-instance` CLI command, or by calling the `RebootDBInstance` API operation. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call, such as calling `ModifyDBInstance` to change DB instance class or scale storage.

When you change a dynamic parameter and save the DB parameter group, the change is applied to the parameter group immediately regardless of the **Apply Immediately** setting. If you use the pending-reboot setting in the AWS CLI or RDS API, the change is still applied to the parameter group immediately. However, applying the parameter change to DB instances that use the parameter group requires a reboot.

If a DB instance isn't using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of **pending-reboot**. The **pending-reboot** parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

- When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the newly associated DB parameter group, these changes are applied immediately without a reboot. For more information about changing the DB parameter group, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

Note

After you change the DB cluster parameter group associated with a DB cluster, reboot the primary DB instance in the cluster to apply the changes to all of the DB instances in the cluster.

To determine whether the primary DB instance of a DB cluster must be rebooted to apply changes, run the following AWS CLI command:

```
aws rds describe-db-clusters --db-cluster-identifier  
db_cluster_identifier
```

Check the `DBClusterParameterGroupStatus` value for the primary DB instance in the output. If the value is `pending-reboot`, then reboot the primary DB instance of the DB cluster.

- You can specify integer and Boolean parameters using expressions, formulas, and functions. Functions can include a mathematical log expression. For more information, see [Specifying DB parameters \(p. 362\)](#).
- Set any parameters that relate to the character set or collation of your database in your parameter group before creating the DB instance and before you create a database in your DB instance. This ensures that the default database and new databases in your DB instance use the character set and collation values that you specify. If you change character set or collation parameters for your DB instance, the parameter changes are not applied to existing databases.

For some DB engines, you can change character set or collation values for an existing database using the `ALTER DATABASE` command, for example:

```
ALTER DATABASE database_name CHARACTER SET character_set_name COLLATE collation;
```

For more information about changing the character set or collation values for a database, check the documentation for your DB engine.

- Improperly setting parameters in a parameter group can have unintended adverse effects, including degraded performance and system instability. Always exercise caution when modifying database parameters and back up your data before modifying a parameter group. Try out parameter group setting changes on a test DB instance before applying those parameter group changes to a production DB instance.
- For an Aurora global database, you can specify different configuration settings for the individual Aurora clusters. Make sure that the settings are similar enough to produce consistent behavior if you promote a secondary cluster to be the primary cluster. For example, use the same settings for time zones and character sets across all the clusters of an Aurora global database.
- To determine the supported parameters for your DB engine, you can view the parameters in the DB parameter group and DB cluster parameter group used by the DB cluster. For more information, see

[Viewing parameter values for a DB parameter group \(p. 359\)](#) and [Viewing parameter values for a DB cluster parameter group \(p. 360\)](#).

Amazon Aurora DB cluster and DB instance parameters

Aurora uses a two-level system of configuration settings, as follows:

- Parameters in a *DB cluster parameter group* apply to every DB instance in a DB cluster. Your data is stored in the Aurora shared storage subsystem. Because of this, all parameters related to physical layout of table data must be the same for all DB instances in an Aurora cluster. Likewise, because Aurora DB instances are connected by replication, all the parameters for replication settings must be identical throughout an Aurora cluster.
- Parameters in a *DB parameter group* apply to a single DB instance in an Aurora DB cluster. These parameters are related to aspects such as memory usage that you can vary across DB instances in the same Aurora cluster. For example, a cluster often contains DB instances with different AWS instance classes.

Every Aurora cluster is associated with a DB cluster parameter group. Each DB instance within the cluster inherits the settings from that DB cluster parameter group, and is associated with a DB parameter group. Aurora assigns default parameter groups when you create a cluster or a new DB instance, based on the specified database engine and version. You can change the parameter groups later to ones that you create, where you can edit the parameter values.

The DB cluster parameter groups also include default values for all the instance-level parameters from the DB parameter group. These defaults are mainly intended for configuring Aurora Serverless clusters, which are only associated with DB cluster parameter groups, not DB parameter groups. You can modify the instance-level parameter settings in the DB cluster parameter group. Then, Aurora applies those settings to each new DB instance that's added to a Serverless cluster. To learn more about configuration

settings for Aurora Serverless clusters and which settings you can modify, see [Parameter groups and Aurora Serverless v1 \(p. 156\)](#).

For non-Serverless clusters, any configuration values that you modify in the DB cluster parameter group override default values in the DB parameter group. If you edit the corresponding values in the DB parameter group, those values override the settings from the DB cluster parameter group.

Any DB parameter settings that you modify take precedence over the DB cluster parameter group values, even if you change the configuration parameters back to their default values. You can see which parameters are overridden by using the `describe-db-parameters` AWS CLI command or the `DescribeDBParameters` RDS API. The `Source` field contains the value `user` if you modified that parameter. To reset one or more parameters so that the value from the DB cluster parameter group takes precedence, use the `reset-db-parameter-group` AWS CLI command or the `ResetDBParameterGroup` RDS API operation.

The DB cluster and DB instance parameters available to you in Aurora vary depending on database engine compatibility.

Database engine	Parameters
Aurora MySQL	See Aurora MySQL configuration parameters (p. 1042) . For Aurora Serverless clusters, see additional details in Parameter groups and Aurora Serverless v1 (p. 156) .
Aurora PostgreSQL	See Amazon Aurora PostgreSQL parameters (p. 1547) .

Creating a DB parameter group

You can create a new DB parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
The **Create parameter group** window appears.
4. In the **Parameter group family** list, select a DB parameter group family.
5. In the **Type** list, select **DB Parameter Group**.
6. In the **Group name** box, enter the name of the new DB parameter group.
7. In the **Description** box, enter a description for the new DB parameter group.
8. Choose **Create**.

AWS CLI

To create a DB parameter group, use the AWS CLI `create-db-parameter-group` command. The following example creates a DB parameter group named `mydbparametergroup` for MySQL version 5.6 with a description of "My new parameter group."

Include the following required parameters:

- `--db-parameter-group-name`
- `--db-parameter-group-family`
- `--description`

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

Note

The output contains duplicates.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
--db-parameter-group-name mydbparametergroup \
--db-parameter-group-family aurora5.6 \
--description "My new parameter group"
```

For Windows:

```
aws rds create-db-parameter-group ^
--db-parameter-group-name mydbparametergroup ^
--db-parameter-group-family aurora5.6 ^
--description "My new parameter group"
```

This command produces output similar to the following:

```
DBPARAMETERGROUP  mydbparametergroup  aurora5.6  My new parameter group
```

RDS API

To create a DB parameter group, use the RDS API [CreateDBParameterGroup](#) operation.

Include the following required parameters:

- `DBParameterGroupName`
- `DBParameterGroupFamily`
- `Description`

Creating a DB cluster parameter group

You can create a new DB cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
The **Create parameter group** window appears.
4. In the **Parameter group family** list, select a DB parameter group family
5. In the **Type** list, select **DB Cluster Parameter Group**.
6. In the **Group name** box, enter the name of the new DB cluster parameter group.
7. In the **Description** box, enter a description for the new DB cluster parameter group.
8. Choose **Create**.

AWS CLI

To create a DB cluster parameter group, use the AWS CLI [create-db-cluster-parameter-group](#) command. The following example creates a DB cluster parameter group named *mydbclusterparametergroup* for MySQL version 5.6 with a description of "My new cluster parameter group."

Include the following required parameters:

- `--db-cluster-parameter-group-name`
- `--db-parameter-group-family`
- `--description`

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

Note

The output contains duplicates.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-parameter-group \
--db-cluster-parameter-group-name mydbclusterparametergroup \
--db-parameter-group-family aurora5.6 \
--description "My new cluster parameter group"
```

For Windows:

```
aws rds create-db-cluster-parameter-group ^
--db-cluster-parameter-group-name mydbclusterparametergroup ^
--db-parameter-group-family aurora5.6 ^
--description "My new cluster parameter group"
```

This command produces output similar to the following:

```
DBCLUSTERPARAMETERGROUP mydbclusterparametergroup mysql5.6 My cluster new parameter
group
```

RDS API

To create a DB cluster parameter group, use the RDS API [CreateDBClusterParameterGroup](#) action.

Include the following required parameters:

- `DBClusterParameterGroupName`
- `DBParameterGroupFamily`
- `Description`

Associating a DB parameter group with a DB instance

You can create your own DB parameter groups with customized settings. You can associate a DB parameter group with a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB instance.

For information about creating a DB parameter group, see [Creating a DB parameter group \(p. 342\)](#). For information about modifying a DB instance, see [Modify a DB instance in a DB cluster \(p. 373\)](#).

Note

When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the newly associated DB parameter group, these changes are applied immediately without a reboot.

Console

To associate a DB parameter group with a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB Instance** page appears.
4. Change the **DB parameter group** setting.
5. Choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause an outage in some cases.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To associate a DB parameter group with a DB instance, use the AWS CLI `modify-db-instance` command with the following options:

- `--db-instance-identifier`
- `--db-parameter-group-name`

The following example associates the `mydbpg` DB parameter group with the `database-1` DB instance. The changes are applied immediately by using `--apply-immediately`. Use `--no-apply-immediately` to apply the changes during the next maintenance window.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier database-1 \
--db-parameter-group-name mydbpg \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier database-1 ^
--db-parameter-group-name mydbpg ^
--apply-immediately
```

RDS API

To associate a DB parameter group with a DB instance, use the RDS API [ModifyDBInstance](#) operation with the following parameters:

- `DBInstanceName`
- `DBParameterGroupName`

Associating a DB cluster parameter group with a DB cluster

You can create your own DB cluster parameter groups with customized settings. You can associate a DB cluster parameter group with a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB cluster.

For information about creating a DB cluster parameter group, see [Creating a DB cluster parameter group \(p. 343\)](#). For information about creating a DB cluster, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#). For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

Note

After you change the DB cluster parameter group associated with a DB cluster, reboot the primary DB instance in the cluster to apply the changes to all of the DB instances in the cluster.

To determine whether the primary DB instance of a DB cluster must be rebooted to apply changes, run the following AWS CLI command:

```
aws rds describe-db-clusters --db-cluster-identifier
db_cluster_identifier
```

Check the `DBClusterParameterGroupStatus` value for the primary DB instance in the output. If the value is `pending-reboot`, then reboot the primary DB instance of the DB cluster.

Console

To associate a DB cluster parameter group with a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then select the DB cluster that you want to modify.

3. Choose **Modify**. The **Modify DB cluster** page appears.
4. Change the **DB cluster parameter group** setting.
5. Choose **Continue** and check the summary of modifications.

The change is applied immediately regardless of the **Scheduling of modifications** setting.

6. On the confirmation page, review your changes. If they are correct, choose **Modify cluster** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To associate a DB cluster parameter group with a DB cluster, use the AWS CLI [modify-db-cluster](#) command with the following options:

- `--db-cluster-name`
- `--db-cluster-parameter-group-name`

The following example associates the `mydbclpg` DB parameter group with the `mydbccluster` DB cluster.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
    --db-cluster-identifier mydbccluster \
    --db-cluster-parameter-group-name mydbclpg
```

For Windows:

```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbccluster ^
    --db-cluster-parameter-group-name mydbclpg
```

RDS API

To associate a DB cluster parameter group with a DB cluster, use the RDS API [ModifyDBCluster](#) operation with the following parameters:

- `DBClusterIdentifier`
- `DBClusterParameterGroupName`

Modifying parameters in a DB parameter group

You can modify parameter values in a customer-created DB parameter group; you can't change the parameter values in a default DB parameter group. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, if the DB instance isn't using the latest changes to its associated DB parameter group, the RDS console shows

the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

The screenshot shows the AWS RDS console interface for managing a DB instance named 'cluster-2-instance-1'. The 'Configuration' tab is selected. In the 'Parameter group' section, the text 'test-aurora56-instance (pending-reboot)' is highlighted with a red box. Other visible details include the DB instance ID, engine version, and instance class.

DB identifier	Role	Engine	Engine version	Region & AZ
cluster-2	Regional	Aurora MySQL	5.6.10a	eu-central-1
cluster-2-instance-1	Writer	Aurora MySQL	5.6.10a	eu-central-1a

Configuration

- DB instance id: cluster-2-instance-1
- Engine version: 5.6.10a
- DB name: -
- Option groups: default:aurora-5-6
- ARN: arn:aws:rds:eu-central-1:...:db:cluster-2-instance-1
- Resource id: db-...
- Created time: Fri Apr 03 2020 10:48:37 GMT-0400 (Eastern Daylight Time)
- Parameter group: test-aurora56-instance (pending-reboot)

Instance class

- Instance class: db.t2.small
- vCPU: 1
- RAM: 2 GB

Availability

- Failover priority: 1

Console

To modify a DB parameter group

- Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
 - In the navigation pane, choose **Parameter groups**.
 - In the list, choose the parameter group that you want to modify.
 - For **Parameter group actions**, choose **Edit**.
 - Change the values of the parameters that you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
- You can't change values in a default parameter group.
- Choose **Save changes**.

AWS CLI

To modify a DB parameter group, use the AWS CLI [modify-db-parameter-group](#) command with the following required options:

- `--db-parameter-group-name`
- `--parameters`

The following example modifies the `max_connections` and `max_allowed_packet` values in the DB parameter group named *mydbparametergroup*.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" \
    "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name mydbparametergroup ^
    --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" ^
    "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBPARAMETERGROUP mydbparametergroup
```

RDS API

To modify a DB parameter group, use the RDS API [ModifyDBParameterGroup](#) operation with the following required parameters:

- `DBParameterGroupName`
- `Parameters`

Modifying parameters in a DB cluster parameter group

You can modify parameter values in a customer-created DB cluster parameter group. You can't change the parameter values in a default DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

Console

To modify a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.
5. Change the values of the parameters you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't change values in a default parameter group.
6. Choose **Save changes**.
7. Reboot the primary DB instance in the cluster to apply the changes to all of the DB instances in the cluster.

AWS CLI

To modify a DB cluster parameter group, use the AWS CLI [modify-db-cluster-parameter-group](#) command with the following required parameters:

- `--db-cluster-parameter-group-name`
- `--parameters`

The following example modifies the `server_audit_logging` and `server_audit_logs_upload` values in the DB cluster parameter group named *mydbclusterparametergroup*.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name mydbclusterparametergroup \
  --parameters
  "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" \
  "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name mydbclusterparametergroup ^
  --parameters
  "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
  "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBCLUSTERPARAMETERGROUP  mydbclusterparametergroup
```

RDS API

To modify a DB cluster parameter group, use the RDS API [ModifyDBClusterParameterGroup](#) command with the following required parameters:

- `DBClusterParameterGroupName`
- `Parameters`

Resetting parameters in a DB parameter group to their default values

You can reset parameter values in a customer-created DB parameter group to their default values. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

When you use the console, you can reset specific parameters to their default values, but you can't easily reset all of the parameters in the DB parameter group at once. When you use the AWS CLI or RDS API, you can reset specific parameters to their default values, and you can reset all of the parameters in the DB parameter group at once.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, if the DB instance isn't using the latest changes to its associated DB parameter group, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

The screenshot shows the AWS RDS console interface. At the top, the navigation path is RDS > Databases > cluster-2 > cluster-2-instance-1. The main title is "cluster-2-instance-1". Below the title, there's a "Related" section with a search bar labeled "Filter databases". A table lists database identifiers: "cluster-2" (Regional, Aurora MySQL 5.6.10a, eu-central-1) and "cluster-2-instance-1" (Writer, Aurora MySQL 5.6.10a, eu-central-1). The "Configuration" tab is highlighted with a red box. Below this, the "Instance" section displays various instance details. The "Parameter group" field at the bottom of the instance details is also highlighted with a red box and contains the value "test-aurora56-instance (pending-reboot)".

Note

In a default DB parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB parameter group to their default values

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't reset values in a default parameter group.
6. Choose **Reset** and then confirm by choosing **Reset parameters**.

AWS CLI

To reset some or all of the parameters in a DB parameter group, use the AWS CLI `reset-db-parameter-group` command with the following required option: `--db-parameter-group-name`.

To reset all of the parameters in the DB parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named `mydbparametergroup` to their default values.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \
--db-parameter-group-name mydbparametergroup \
--reset-all-parameters
```

For Windows:

```
aws rds reset-db-parameter-group ^
--db-parameter-group-name mydbparametergroup ^
--reset-all-parameters
```

The following example resets the `max_connections` and `max_allowed_packet` options to their default values in the DB parameter group named `mydbparametergroup`.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \
--db-parameter-group-name mydbparametergroup \
--parameters "ParameterName=max_connections,ApplyMethod=immediate" \
"ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-parameter-group ^
--db-parameter-group-name mydbparametergroup ^
--parameters "ParameterName=max_connections,ApplyMethod=immediate" ^
"ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBParameterGroupName mydbparametergroup
```

RDS API

To reset parameters in a DB parameter group to their default values, use the RDS API [ResetDBParameterGroup](#) command with the following required parameter: `DBParameterGroupName`.

To reset all of the parameters in the DB parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

Resetting parameters in a DB cluster parameter group

You can reset parameters to their default values in a customer-created DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

Note

In a default DB cluster parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB cluster parameter group to their default values

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't reset values in a default parameter group.
6. Choose **Reset** and then confirm by choosing **Reset parameters**.
7. Reboot the primary DB instance in the DB cluster to apply the changes to all of the DB instances in the DB cluster.

AWS CLI

To reset parameters in a DB cluster parameter group to their default values, use the AWS CLI [reset-db-cluster-parameter-group](#) command with the following required option: `--db-cluster-parameter-group-name`.

To reset all of the parameters in the DB cluster parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named *mydbparametergroup* to their default values.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group \
--db-cluster-parameter-group-name mydbparametergroup \
--reset-all-parameters
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
--db-cluster-parameter-group-name mydbparametergroup ^
--reset-all-parameters
```

The following example resets the `server_audit_logging` and `server_audit_logs_upload` to their default values in the DB cluster parameter group named *mydbclusterparametergroup*.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-cluster-parameter-group \
--db-cluster-parameter-group-name mydbclusterparametergroup \
--parameters "ParameterName=server_audit_logging,ApplyMethod=immediate" \
"ParameterName=server_audit_logs_upload,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-cluster-parameter-group ^
--db-cluster-parameter-group-name mydbclusterparametergroup ^
--parameters
"ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
"ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBClusterParameterGroupName mydbclusterparametergroup
```

RDS API

To reset parameters in a DB cluster parameter group to their default values, use the RDS API [ResetDBClusterParameterGroup](#) command with the following required parameter: `DBClusterParameterGroupName`.

To reset all of the parameters in the DB cluster parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

Copying a DB parameter group

You can copy custom DB parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB parameter group and you want to include most of the

custom parameters and values from that group in a new DB parameter group. You can copy a DB parameter group by using the AWS Management Console, the AWS CLI [copy-db-parameter-group](#) command, or the RDS API [CopyDBParameterGroup](#) operation.

After you copy a DB parameter group, wait at least 5 minutes before creating your first DB instance that uses that DB parameter group as the default parameter group. Doing this allows Amazon RDS to fully complete the copy action before the parameter group is used. This is especially important for parameters that are critical when creating the default database for a DB instance. An example is the character set for the default database defined by the `character_set_database` parameter. Use the **Parameter Groups** option of the [Amazon RDS console](#) or the [describe-db-parameters](#) command to verify that your DB parameter group is created.

Note

You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

Currently, you can't copy a parameter group to a different AWS Region.

Console

To copy a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the custom parameter group that you want to copy.
4. For **Parameter group actions**, choose **Copy**.
5. In **New DB parameter group identifier**, enter a name for the new parameter group.
6. In **Description**, enter a description for the new parameter group.
7. Choose **Copy**.

AWS CLI

To copy a DB parameter group, use the AWS CLI [copy-db-parameter-group](#) command with the following required options:

- `--source-db-parameter-group-identifier`
- `--target-db-parameter-group-identifier`
- `--target-db-parameter-group-description`

The following example creates a new DB parameter group named `mygroup2` that is a copy of the DB parameter group `mygroup1`.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-parameter-group \
--source-db-parameter-group-identifier mygroup1 \
--target-db-parameter-group-identifier mygroup2 \
--target-db-parameter-group-description "DB parameter group 2"
```

For Windows:

```
aws rds copy-db-parameter-group ^
```

```
--source-db-parameter-group-identifier mygroup1 ^
--target-db-parameter-group-identifier mygroup2 ^
--target-db-parameter-group-description "DB parameter group 2"
```

RDS API

To copy a DB parameter group, use the RDS API [CopyDBParameterGroup](#) operation with the following required parameters:

- `SourceDBParameterGroupIdentifier`
- `TargetDBParameterGroupIdentifier`
- `TargetDBParameterGroupDescription`

Copying a DB cluster parameter group

You can copy custom DB cluster parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB cluster parameter group and you want to include most of the custom parameters and values from that group in a new DB cluster parameter group. You can copy a DB cluster parameter group by using the AWS CLI [copy-db-cluster-parameter-group](#) command or the RDS API [CopyDBClusterParameterGroup](#) operation.

After you copy a DB cluster parameter group, wait at least 5 minutes before creating your first DB cluster that uses that DB cluster parameter group as the default parameter group. Doing this allows Amazon RDS to fully complete the copy action before the parameter group is used as the default for a new DB cluster. You can use the **Parameter Groups** option of the [Amazon RDS console](#) or the `describe-db-cluster-parameters` command to verify that your DB cluster parameter group is created.

Note

You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

Console

To copy a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the custom parameter group that you want to copy.
4. For **Parameter group actions**, choose **Copy**.
5. In **New DB parameter group identifier**, enter a name for the new parameter group.
6. In **Description**, enter a description for the new parameter group.
7. Choose **Copy**.

AWS CLI

To copy a DB cluster parameter group, use the AWS CLI [copy-db-cluster-parameter-group](#) command with the following required parameters:

- `--source-db-cluster-parameter-group-identifier`
- `--target-db-cluster-parameter-group-identifier`
- `--target-db-cluster-parameter-group-description`

The following example creates a new DB cluster parameter group named `mygroup2` that is a copy of the DB cluster parameter group `mygroup1`.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-cluster-parameter-group \
--source-db-cluster-parameter-group-identifier mygroup1 \
--target-db-cluster-parameter-group-identifier mygroup2 \
--target-db-cluster-parameter-group-description "DB parameter group 2"
```

For Windows:

```
aws rds copy-db-cluster-parameter-group ^
--source-db-cluster-parameter-group-identifier mygroup1 ^
--target-db-cluster-parameter-group-identifier mygroup2 ^
--target-db-cluster-parameter-group-description "DB parameter group 2"
```

RDS API

To copy a DB cluster parameter group, use the RDS API [CopyDBClusterParameterGroup](#) operation with the following required parameters:

- `SourceDBClusterParameterGroupIdentifier`
- `TargetDBClusterParameterGroupIdentifier`
- `TargetDBClusterParameterGroupDescription`

Listing DB parameter groups

You can list the DB parameter groups you've created for your AWS account.

Note

Default parameter groups are automatically created from a default parameter template when you create a DB instance for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

Console

To list all DB parameter groups for an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.

The DB parameter groups appear in a list.

AWS CLI

To list all DB parameter groups for an AWS account, use the AWS CLI [describe-db-parameter-groups](#) command.

Example

The following example lists all available DB parameter groups for an AWS account.

```
aws rds describe-db-parameter-groups
```

The command returns a response like the following:

```
DBPARAMETERGROUP default.mysql5.6      mysql5.6  Default parameter group for MySQL5.6
DBPARAMETERGROUP mydbparametergroup     mysql5.6  My new parameter group
```

The following example describes the *mydbparamgroup1* parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-parameter-groups \
--db-parameter-group-name mydbparamgroup1
```

For Windows:

```
aws rds describe-db-parameter-groups ^
--db-parameter-group-name mydbparamgroup1
```

The command returns a response like the following:

```
DBPARAMETERGROUP mydbparametergroup1  mysql5.6  My new parameter group
```

RDS API

To list all DB parameter groups for an AWS account, use the RDS API [DescribeDBParameterGroups](#) operation.

Listing DB cluster parameter groups

You can list the DB cluster parameter groups you've created for your AWS account.

Note

Default parameter groups are automatically created from a default parameter template when you create a DB cluster for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

Console

To list all DB cluster parameter groups for an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.

The DB cluster parameter groups appear in the list with **DB cluster parameter group** for Type.

AWS CLI

To list all DB cluster parameter groups for an AWS account, use the AWS CLI [describe-db-cluster-parameter-groups](#) command.

Example

The following example lists all available DB cluster parameter groups for an AWS account.

```
aws rds describe-db-cluster-parameter-groups
```

The command returns a response like the following:

```
DBCLUSTERPARAMETERGROUPS      arn:aws:rds:us-west-2:1234567890:cluster-
pg:default.aurora5.6 default.aurora5.6      aurora5.6      Default cluster parameter
group for aurora5.6
DBCLUSTERPARAMETERGROUPS      arn:aws:rds:us-west-2:1234567890:cluster-
pg:mydbclusterparametergroup mydbclusterparametergroup      aurora5.6      My new cluster
parameter group
```

The following example describes the *mydbclusterparametergroup* parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameter-groups \
--db-cluster-parameter-group-name mydbclusterparametergroup
```

For Windows:

```
aws rds describe-db-cluster-parameter-groups ^
--db-cluster-parameter-group-name mydbclusterparametergroup
```

The command returns a response like the following:

```
DBCLUSTERPARAMETERGROUPS      arn:aws:rds:us-west-2:1234567890:cluster-
pg:mydbclusterparametergroup mydbclusterparametergroup      aurora5.6      My new cluster
parameter group
```

RDS API

To list all DB cluster parameter groups for an AWS account, use the RDS API [DescribeDBClusterParameterGroups](#) action.

Viewing parameter values for a DB parameter group

You can get a list of all parameters in a DB parameter group and their values.

Console

To view the parameter values for a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.

The DB parameter groups appear in a list.

3. Choose the name of the parameter group to see its list of parameters.

AWS CLI

To view the parameter values for a DB parameter group, use the AWS CLI [describe-db-parameters](#) command with the following required parameter.

- `--db-parameter-group-name`

Example

The following example lists the parameters and parameter values for a DB parameter group named *mydbparametergroup*.

```
aws rds describe-db-parameters --db-parameter-group-name mydbparametergroup
```

The command returns a response like the following:

DBPARAMETER	Parameter Name	Parameter Value	Source	Data Type	Apply
DBPARAMETER	Type	Is Modifiable			
DBPARAMETER	allow-suspicious-udfs	false	engine-default	boolean	static
DBPARAMETER	auto_increment_increment	true	engine-default	integer	dynamic
DBPARAMETER	auto_increment_offset	true	engine-default	integer	dynamic
DBPARAMETER	binlog_cache_size	32768	system	integer	dynamic
DBPARAMETER	socket	/tmp/mysql.sock	system	string	static

RDS API

To view the parameter values for a DB parameter group, use the RDS API [DescribeDBParameters](#) command with the following required parameter.

- `DBParameterGroupName`

Viewing parameter values for a DB cluster parameter group

You can get a list of all parameters in a DB cluster parameter group and their values.

Console

To view the parameter values for a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.

The DB cluster parameter groups appear in the list with **DB cluster parameter group** for **Type**.

3. Choose the name of the DB cluster parameter group to see its list of parameters.

AWS CLI

To view the parameter values for a DB cluster parameter group, use the AWS CLI [describe-db-cluster-parameters](#) command with the following required parameter.

- `--db-cluster-parameter-group-name`

Example

The following example lists the parameters and parameter values for a DB cluster parameter group named *mydbcclusterparametergroup*, in JSON format.

The command returns a response like the following:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name mydbcclusterparametergroup
```

```
{  
    "Parameters": [  
        {  
            "ApplyMethod": "pending-reboot",  
            "Description": "Controls whether user-defined functions that have only an xxx symbol for the main function can be loaded",  
            "DataType": "boolean",  
            "AllowedValues": "0,1",  
            "SupportedEngineModes": [  
                "provisioned"  
            ],  
            "Source": "engine-default",  
            "IsModifiable": false,  
            "ParameterName": "allow-suspicious-udfs",  
            "ApplyType": "static"  
        },  
        {  
            "ApplyMethod": "pending-reboot",  
            "Description": "Enables new features in the Aurora engine.",  
            "DataType": "boolean",  
            "IsModifiable": true,  
            "AllowedValues": "0,1",  
            "SupportedEngineModes": [  
                "provisioned"  
            ],  
            "Source": "engine-default",  
            "ParameterValue": "0",  
            "ParameterName": "aurora_lab_mode",  
            "ApplyType": "static"  
        },  
        ...  
    ]  
}
```

The following example lists the parameters and parameter values for a DB cluster parameter group named *mydbcclusterparametergroup*, in plain text format.

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name mydbcclusterparametergroup --output text
```

The command returns a response like the following:

```
PARAMETERS 0,1 pending-reboot static boolean Controls whether user-defined functions
  that have only an xxx symbol for the main function can be loaded False allow-suspicious-
  udfs engine-default SUPPORTEDENGINEMODES provisioned
PARAMETERS 0,1 pending-reboot static boolean Enables new features in the Aurora
  engine. True aurora_lab_mode 0 engine-default SUPPORTEDENGINEMODES provisioned
...
```

RDS API

To view the parameter values for a DB cluster parameter group, use the RDS API [DescribeDBClusterParameters](#) command with the following required parameter.

- `DBClusterParameterGroupName`

Comparing parameter groups

You can use the AWS Management Console to view the differences between two parameter groups for the same DB engine and version.

To compare two parameter groups

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the two parameter groups that you want to compare.
4. For **Parameter group actions**, choose **Compare**.

Note

If the items you selected aren't equivalent, you can't choose **Compare**. For example, you can't compare a MySQL 5.6 and a MySQL 5.7 parameter group. You can't compare a DB parameter group and an Aurora DB cluster parameter group.

Specifying DB parameters

DB parameter types include the following:

- Integer
- Boolean
- String
- Long
- Double
- Timestamp
- Object of other defined data types
- Array of values of type integer, Boolean, string, long, double, timestamp, or object

You can also specify integer and Boolean parameters using expressions, formulas, and functions.

Contents

- [DB parameter formulas \(p. 363\)](#)
 - [DB parameter formula variables \(p. 363\)](#)
 - [DB parameter formula operators \(p. 363\)](#)
- [DB parameter functions \(p. 364\)](#)

- [DB parameter log expressions \(p. 364\)](#)
- [DB parameter value examples \(p. 365\)](#)

DB parameter formulas

A DB parameter formula is an expression that resolves to an integer value or a Boolean value. You enclose the expression in braces: {}. You can use a formula for either a DB parameter value or as an argument to a DB parameter function.

Syntax

```
{FormulaVariable}  
{FormulaVariable*Integer}  
{FormulaVariable*Integer/Integer}  
{FormulaVariable/Integer}
```

DB parameter formula variables

Each formula variable returns an integer or a Boolean value. The names of the variables are case-sensitive.

AllocatedStorage

Returns an integer representing the size, in bytes, of the data volume.

DBInstanceClassMemory

Returns an integer for the number of bytes of memory available to the database process. This number is internally calculated by taking the total amount of memory for the DB instance class and subtracting memory reserved for the operating system and the RDS processes that manage the instance. Therefore, the number is always somewhat lower than the memory figures shown in the instance class tables in [Aurora DB instance classes \(p. 54\)](#). The exact value depends on a combination of instance class, DB engine, and whether it applies to an RDS instance or an instance that's part of an Aurora cluster.

EndPointPort

Returns an integer representing the port used when connecting to the DB instance.

DB parameter formula operators

DB parameter formulas support two operators: division and multiplication.

Division operator: /

Divides the dividend by the divisor, returning an integer quotient. Decimals in the quotient are truncated, not rounded.

Syntax

```
dividend / divisor
```

The dividend and divisor arguments must be integer expressions.

*Multiplication operator: **

Multiplies the expressions, returning the product of the expressions. Decimals in the expressions are truncated, not rounded.

Syntax

```
expression * expression
```

Both expressions must be integers.

DB parameter functions

You specify the arguments of DB parameter functions as either integers or formulas. Each function must have at least one argument. Specify multiple arguments as a comma-separated list. The list can't have any empty members, such as *argument1,,argument3*. Function names are case-insensitive.

IF

Returns an argument.

Syntax

```
IF(argument1, argument2, argument3)
```

Returns the second argument if the first argument evaluates to true. Returns the third argument otherwise.

GREATEST

Returns the largest value from a list of integers or parameter formulas.

Syntax

```
GREATEST(argument1, argument2,...argumentn)
```

Returns an integer.

LEAST

Returns the smallest value from a list of integers or parameter formulas.

Syntax

```
LEAST(argument1, argument2,...argumentn)
```

Returns an integer.

SUM

Adds the values of the specified integers or parameter formulas.

Syntax

```
SUM(argument1, argument2,...argumentn)
```

Returns an integer.

DB parameter log expressions

You can set an integer DB parameter value to a log expression. You enclose the expression in braces: {}.

For example:

```
{log(DBInstanceClassMemory/8187281418)*1000}
```

The `log` function represents log base 2. This example also uses the `DBInstanceClassMemory` formula variable. See [DB parameter formula variables \(p. 363\)](#).

DB parameter value examples

These examples show using formulas, functions, and expressions for the values of DB parameters.

Note

DB Parameter functions are currently supported only in the console and aren't supported in the AWS CLI.

Warning

Improperly setting parameters in a DB parameter group can have unintended adverse effects. These might include degraded performance and system instability. Use caution when modifying database parameters and back up your data before modifying your DB parameter group. Try out parameter group changes on a test DB instance, created using point-in-time-restores, before applying those parameter group changes to your production DB instances.

Example using the DB parameter function LEAST

You can specify the `LEAST` function in an Aurora MySQL `table_definition_cache` parameter value. Use it to set the number of table definitions that can be stored in the definition cache to the lesser of `DBInstanceClassMemory/393040` or 20,000.

```
LEAST({DBInstanceClassMemory/393040}, 20000)
```

Migrating data to an Amazon Aurora DB cluster

You have several options for migrating data from your existing database to an Amazon Aurora DB cluster, depending on database engine compatibility. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating.

Migrating data to an Amazon Aurora MySQL DB cluster

You can migrate data from one of the following sources to an Amazon Aurora MySQL DB cluster.

- An RDS for MySQL DB instance
- A MySQL database external to Amazon RDS
- A database that is not MySQL-compatible

For more information, see [Migrating data to an Amazon Aurora MySQL DB cluster \(p. 781\)](#).

Migrating data to an Amazon Aurora PostgreSQL DB cluster

You can migrate data from one of the following sources to an Amazon Aurora PostgreSQL DB cluster.

- An Amazon RDS PostgreSQL DB instance
- A database that is not PostgreSQL-compatible

For more information, see [Migrating data to Amazon Aurora with PostgreSQL compatibility \(p. 1283\)](#).

Managing an Amazon Aurora DB cluster

This section shows how to manage and maintain your Aurora DB cluster. Aurora involves clusters of database servers that are connected in a replication topology. Thus, managing Aurora often involves deploying changes to multiple servers and making sure that all Aurora Replicas are keeping up with the master server. Because Aurora transparently scales the underlying storage as your data grows, managing Aurora requires relatively little management of disk storage. Likewise, because Aurora automatically performs continuous backups, an Aurora cluster does not require extensive planning or downtime for performing backups.

Stopping and starting an Amazon Aurora DB cluster

Stopping and starting Amazon Aurora clusters helps you manage costs for development and test environments. You can temporarily stop all the DB instances in your cluster, instead of setting up and tearing down all the DB instances each time that you use the cluster.

Topics

- [Overview of stopping and starting an Aurora DB cluster \(p. 368\)](#)
- [Limitations for stopping and starting Aurora DB clusters \(p. 368\)](#)
- [Stopping an Aurora DB cluster \(p. 369\)](#)
- [Possible operations while an Aurora DB cluster is stopped \(p. 370\)](#)
- [Starting an Aurora DB cluster \(p. 370\)](#)

Overview of stopping and starting an Aurora DB cluster

During periods where you don't need an Aurora cluster, you can stop all instances in that cluster at once. You can start the cluster again anytime you need to use it. Starting and stopping simplifies the setup and teardown processes for clusters used for development, testing, or similar activities that don't require continuous availability. You can perform all the AWS Management Console procedures involved with only a single action, regardless of how many instances are in the cluster.

While your DB cluster is stopped, you are charged only for cluster storage, manual snapshots, and automated backup storage within your specified retention window. You aren't charged for any DB instance hours. Aurora automatically starts your DB cluster after seven days so that it doesn't fall behind any required maintenance updates.

To minimize charges for a lightly loaded Aurora cluster, you can stop the cluster instead of deleting all of its Aurora Replicas. For clusters with more than one or two instances, frequently deleting and recreating the DB instances is only practical using the AWS CLI or Amazon RDS API. Such a sequence of operations can also be difficult to perform in the right order, for example to delete all Aurora Replicas before deleting the primary instance to avoid activating the failover mechanism.

Don't use starting and stopping if you need to keep your DB cluster running but it has more capacity than you need. If your cluster is too costly or not very busy, delete one or more DB instances or change all your DB instances to a small instance class. You can't stop an individual Aurora DB instance.

Limitations for stopping and starting Aurora DB clusters

Some Aurora clusters can't be stopped and started:

- You can't stop and start a cluster that's part of an [Aurora global database \(p. 225\)](#).
- For a cluster that uses the [Aurora parallel query \(p. 881\)](#) feature, the minimum Aurora MySQL versions are 1.23.0 and 2.09.0.
- You can't stop and start an [Aurora Serverless cluster \(p. 147\)](#).
- You can't stop and start an [Aurora multi-master cluster \(p. 958\)](#).

If an existing cluster can't be stopped and started, the **Stop** action isn't available from the **Actions** menu on the **Databases** page or the details page.

Stopping an Aurora DB cluster

To use an Aurora DB cluster or perform administration, you always begin with a running Aurora DB cluster, then stop the cluster, and then start the cluster again. While your cluster is stopped, you are charged for cluster storage, manual snapshots, and automated backup storage within your specified retention window, but not for DB instance hours.

The stop operation stops the Aurora Replica instances first, then the primary instance, to avoid activating the failover mechanism.

You can't stop a DB cluster that acts as the replication target for data from another DB cluster, or acts as the replication master and transmits data to another cluster.

You can't stop certain special kinds of clusters. Currently, you can't stop a cluster that's part of an Aurora global database, or a multi-master cluster.

Console

To stop an Aurora cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose a cluster. You can perform the stop operation from this page, or navigate to the details page for the DB cluster that you want to stop.

If an existing cluster can't be stopped and started, the **Stop** action isn't available from the **Actions** menu on the **Databases** page or the details page. For the kinds of clusters that you can't start and stop, see [Limitations for stopping and starting Aurora DB clusters \(p. 368\)](#).
3. For **Actions**, choose **Stop**.

AWS CLI

To stop a DB instance by using the AWS CLI, call the `stop-db-cluster` command with the following parameters:

- `--db-cluster-identifier` – the name of the Aurora cluster.

Example

```
aws rds stop-db-cluster --db-cluster-identifier mydbcluster
```

RDS API

To stop a DB instance by using the Amazon RDS API, call the `StopDBCluster` operation with the following parameter:

- `DBClusterIdentifier` – the name of the Aurora cluster.

Possible operations while an Aurora DB cluster is stopped

While an Aurora cluster is stopped, you can do a point-in-time restore to any point within your specified automated backup retention window. For details about doing a point-in-time restore, see [Restoring data \(p. 493\)](#).

You can't modify the configuration of an Aurora DB cluster, or any of its DB instances, while the cluster is stopped. You also can't add or remove DB instances from the cluster, or delete the cluster if it still has any associated DB instances. You must start the cluster before performing any such administrative actions.

Stopping a DB cluster removes pending actions, except for the DB cluster parameter group or for the DB parameter groups of the DB cluster instances.

Aurora applies any scheduled maintenance to your stopped cluster after it's started again. Remember that after seven days, Aurora automatically starts any stopped clusters so that they don't fall too far behind in their maintenance status.

Aurora also doesn't perform any automated backups, because the underlying data can't change while the cluster is stopped. Aurora doesn't extend the backup retention period while the cluster is stopped.

Starting an Aurora DB cluster

You always start an Aurora DB cluster beginning with an Aurora cluster that is already in the stopped state. When you start the cluster, all its DB instances become available again. The cluster keeps its configuration settings such as endpoints, parameter groups, and VPC security groups.

Console

To start an Aurora cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose a cluster. You can perform the start operation from this page, or navigate to the details page for the DB cluster that you want to start.
3. For **Actions**, choose **Start**.

AWS CLI

To start a DB cluster by using the AWS CLI, call the `start-db-cluster` command with the following parameters:

- `--db-cluster-identifier` – the name of the Aurora cluster. This name is either a specific cluster identifier you chose when creating the cluster, or the DB instance identifier you chose with `-cluster` appended to the end.

Example

```
aws rds start-db-cluster --db-cluster-identifier mydbcluster
```

RDS API

To start an Aurora DB cluster by using the Amazon RDS API, call the `StartDBCluster` operation with the following parameter:

- **DBCluster** – the name of the Aurora cluster. This name is either a specific cluster identifier you chose when creating the cluster, or the DB instance identifier you chose with `-cluster` appended to the end.

Modifying an Amazon Aurora DB cluster

You can change the settings of a DB cluster to accomplish tasks such as changing its backup retention period or its database port. You can also modify DB instances in a DB cluster to accomplish tasks such as changing its DB instance class or enabling Performance Insights for it. This topic guides you through modifying an Aurora DB cluster and its DB instances, and describes the settings for each.

We recommend that you test any changes on a test DB cluster or DB instance before modifying a production DB cluster or DB instance, so that you fully understand the impact of each change. This is especially important when upgrading database versions.

Modifying the DB cluster by using the console, CLI, and API

You can modify a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Note

For Aurora, when you modify a DB cluster, only changes to the **DB cluster identifier**, **IAM DB authentication**, and **New master password** settings are affected by the **Apply immediately** setting. All other modifications are applied immediately, regardless of the value of the **Apply immediately** setting.

Console

To modify a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then select the DB cluster that you want to modify.
3. Choose **Modify**. The **Modify DB cluster** page appears.
4. Change any of the settings that you want. For information about each setting, see [Settings for Amazon Aurora \(p. 375\)](#).

Note

In the AWS Management Console, some instance level changes only apply to the current DB instance, while others apply to the entire DB cluster. For information about whether a setting applies to the DB instance or the DB cluster, see the scope for the setting in [Settings for Amazon Aurora \(p. 375\)](#). To change a setting that modifies the entire DB cluster at the instance level in the AWS Management Console, follow the instructions in [Modify a DB instance in a DB cluster \(p. 373\)](#).

5. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, select **Apply immediately**.
7. On the confirmation page, review your changes. If they are correct, choose **Modify cluster** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To modify a DB cluster using the AWS CLI, call the `modify-db-cluster` command. Specify the DB cluster identifier, and the values for the settings that you want to modify. For information about each setting, see [Settings for Amazon Aurora \(p. 375\)](#).

Note

Some settings only apply to DB instances. To change those settings, follow the instructions in [Modify a DB instance in a DB cluster \(p. 373\)](#).

Example

The following command modifies `mydbcluster` by setting the backup retention period to 1 week (7 days).

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
--db-cluster-identifier mydbcluster \
--backup-retention-period 7
```

For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier mydbcluster ^
--backup-retention-period 7
```

RDS API

To modify a DB cluster using the Amazon RDS API, call the [ModifyDBCluster](#) operation. Specify the DB cluster identifier, and the values for the settings that you want to modify. For information about each parameter, see [Settings for Amazon Aurora \(p. 375\)](#).

Note

Some settings only apply to DB instances. To change those settings, follow the instructions in [Modify a DB instance in a DB cluster \(p. 373\)](#).

Modify a DB instance in a DB cluster

You can modify a DB instance in a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

When you modify a DB instance, you can apply the changes immediately. To apply changes immediately, you select the **Apply Immediately** option in the AWS Management Console, you use the `--apply-immediately` parameter when calling the AWS CLI, or you set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API.

If you don't choose to apply changes immediately, the changes are deferred until the next maintenance window. During the next maintenance window, any of these deferred changes are applied. If you choose to apply changes immediately, your new changes and any previously deferred changes are applied.

Important

If any of the deferred modifications require downtime, choosing **Apply immediately** can cause unexpected downtime for the DB instance. There is no downtime for the other DB instances in the DB cluster.

Modifications that you defer aren't listed in the output of the `describe-pending-maintenance-actions` CLI command. Maintenance actions only include system upgrades that you schedule for the next maintenance window.

Console

To modify a DB instance in a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Databases**, and then select the DB instance that you want to modify.
3. For **Actions**, choose **Modify**. The **Modify DB Instance** page appears.
4. Change any of the settings that you want. For information about each setting, see [Settings for Amazon Aurora \(p. 375\)](#).

Note

Some settings apply to the entire DB cluster and must be changed at the cluster level. To change those settings, follow the instructions in [Modifying the DB cluster by using the console, CLI, and API \(p. 372\)](#).

In the AWS Management Console, some instance level changes only apply to the current DB instance, while others apply to the entire DB cluster. For information about whether a setting applies to the DB instance or the DB cluster, see the scope for the setting in [Settings for Amazon Aurora \(p. 375\)](#).

5. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, select **Apply immediately**.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To modify a DB instance in a DB cluster by using the AWS CLI, call the `modify-db-instance` command. Specify the DB instance identifier, and the values for the settings that you want to modify. For information about each parameter, see [Settings for Amazon Aurora \(p. 375\)](#).

Note

Some settings apply to the entire DB cluster. To change those settings, follow the instructions in [Modifying the DB cluster by using the console, CLI, and API \(p. 372\)](#).

Example

The following code modifies `mydbinstance` by setting the DB instance class to `db.r4.xlarge`. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--db-instance-class db.r4.xlarge \
--no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--db-instance-class db.r4.xlarge ^
--no-apply-immediately
```

RDS API

To modify a MySQL instance by using the Amazon RDS API, call the `ModifyDBInstance` operation. Specify the DB instance identifier, and the values for the settings that you want to modify. For information about each parameter, see [Settings for Amazon Aurora \(p. 375\)](#).

Note

Some settings apply to the entire DB cluster. To change those settings, follow the instructions in [Modifying the DB cluster by using the console, CLI, and API \(p. 372\)](#).

Settings for Amazon Aurora

The following table contains details about which settings you can modify, the methods for modifying the setting, and the scope of the setting. The scope determines whether the setting applies to the entire DB cluster or if it can be set only for specific DB instances.

Note

Additional settings are available if you are modifying an Aurora Serverless DB cluster. For information about these settings, see [Modifying an Aurora Serverless v1 DB cluster \(p. 170\)](#).

Also, some settings aren't available for Aurora Serverless because of Aurora Serverless limitations. For more information, see [Limitations of Aurora Serverless v1 \(p. 148\)](#).

Setting and description	Method	Scope	Downtime notes
<p>Auto minor version upgrade</p> <p>Whether you want the DB instance to receive preferred minor engine version upgrades automatically when they become available. Upgrades are installed only during your scheduled maintenance window.</p> <p>For more information about engine updates, see Amazon Aurora PostgreSQL updates (p. 1597) and Database engine updates for Amazon Aurora MySQL (p. 1082). For more information about the Auto minor version upgrade setting for Aurora MySQL, see Enabling automatic upgrades between minor Aurora MySQL versions (p. 1089).</p>	<p>Note</p> <p>This setting is enabled by default. For each new cluster, choose the appropriate value for this setting based on its importance, expected lifetime, and the amount of verification testing that you do after each upgrade.</p> <p>When you change this setting, perform this modification for every DB instance in your Aurora cluster. If any DB instance in your cluster has this setting turned off, the cluster isn't automatically upgraded.</p> <p>Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373).</p> <p>Using the AWS CLI, run <code>modify-db-instance</code></p>	The entire DB cluster	An outage doesn't occur during this change. Outages do occur during future maintenance windows when Aurora applies automatic upgrades.

Setting and description	Method	Scope	Downtime notes
	<p>and set the <code>--auto-minor-version-upgrade</code> <code>--no-auto-minor-version-upgrade</code> option.</p> <p>Using the RDS API, call ModifyDBInstance and set the <code>AutoMinorVersionUpgrade</code> parameter.</p>		
Backup retention period The number of days that automatic backups are retained. The minimum value is 1. For more information, see Backups (p. 491) .	<p>Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372).</p> <p>Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--backup-retention-period</code> option.</p> <p>Using the RDS API, call ModifyDBCluster and set the <code>BackupRetentionPeriod</code> parameter.</p>	The entire DB cluster	An outage doesn't occur during this change.

Setting and description	Method	Scope	Downtime notes
<p>Backup window (Start time)</p> <p>The time range during which automated backups of your database occurs. The backup window is a start time in Universal Coordinated Time (UTC), and a duration in hours.</p> <p>Aurora backups are continuous and incremental, but the backup window is used to create a daily system backup that is preserved within the backup retention period. You can copy it to preserve it outside of the retention period.</p> <p>The maintenance window and the backup window for the DB cluster can't overlap.</p> <p>For more information, see Backup window (p. 491).</p>	<p>Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372).</p> <p>Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--preferred-backup-window</code> option.</p> <p>Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>PreferredBackupWindow</code> parameter.</p>	The entire DB cluster.	An outage doesn't occur during this change.
<p>Certificate Authority</p> <p>The certificate that you want to use.</p>	<p>Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373).</p> <p>Using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--ca-certificate-identifier</code> option.</p> <p>Using the RDS API, call <code>ModifyDBInstance</code> and set the <code>CACertificateIdentifier</code> parameter.</p>	Only the specified DB instance	An outage occurs during this change. The DB instance is rebooted.

Setting and description	Method	Scope	Downtime notes
Copy tags to snapshots Select to specify that tags defined for this DB cluster are copied to DB snapshots created from this DB cluster. For more information, see Tagging Amazon RDS resources (p. 474) .	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--copy-tags-to-snapshot</code> or <code>--no-copy-tags-to-snapshot</code> option. Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>CopyTagsToSnapshot</code> parameter.	The entire DB cluster	An outage doesn't occur during this change.
Data API You can access Aurora Serverless with web services-based applications, including AWS Lambda and AWS AppSync. This setting only applies to an Aurora Serverless DB cluster. For more information, see Using the Data API for Aurora Serverless (p. 178) .	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--enable-http-endpoint</code> option. Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>EnableHttpEndpoint</code> parameter.	The entire DB cluster	An outage doesn't occur during this change.

Setting and description	Method	Scope	Downtime notes
<p>Database authentication The database authentication you want to use.</p> <p>For MySQL:</p> <ul style="list-style-type: none"> Choose Password authentication to authenticate database users with database passwords only. Choose Password and IAM database authentication to authenticate database users with database passwords and user credentials through IAM users and roles. For more information, see IAM database authentication (p. 1743). <p>For PostgreSQL:</p> <ul style="list-style-type: none"> Choose IAM database authentication to authenticate database users with database passwords and user credentials through IAM users and roles. For more information, see IAM database authentication (p. 1743). Choose Kerberos authentication to authenticate database passwords and user credentials using Kerberos authentication. For more information, see Using Kerberos authentication with Aurora PostgreSQL (p. 1534). 	<p>Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372).</p> <p>Using the AWS CLI, run <code>modify-db-cluster</code> and set the following options:</p> <ul style="list-style-type: none"> For IAM authentication, set the <code>--enable-iam-database-authentication --no-enable-iam-database-authentication</code> option. For Kerberos authentication, set the <code>--domain</code> and <code>--domain-iam-role-name</code> options. <p>Using the RDS API, call <code>ModifyDBCluster</code> and set the following parameters:</p> <ul style="list-style-type: none"> For IAM authentication, set the <code>EnableIAMDatabaseAuthentication</code> parameter. For Kerberos authentication, set the <code>Domain</code> and <code>DomainIAMRoleName</code> parameters. 	The entire DB cluster	An outage doesn't occur during this change.

Setting and description	Method	Scope	Downtime notes
Database port The port that you want to use to access the DB cluster.	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--port</code> option. Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>Port</code> parameter.	The entire DB cluster	An outage occurs during this change. All of the DB instances in the DB cluster are rebooted immediately.
DB cluster identifier The DB cluster identifier. This value is stored as a lowercase string. When you change the DB cluster identifier, the DB cluster endpoint changes, and the endpoints of the DB instances in the DB cluster change.	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--new-db-cluster-identifier</code> option. Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>NewDBClusterIdentifier</code> parameter.	The entire DB cluster	An outage doesn't occur during this change.
DB cluster parameter group The DB cluster parameter group that you want associated with the DB cluster. For more information, see Working with DB parameter groups and DB cluster parameter groups (p. 339) .	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--db-cluster-parameter-group-name</code> option. Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>DBClusterParameterGroupName</code> parameter.	The entire DB cluster	An outage doesn't occur during this change. When you change the parameter group, changes to some parameters are applied to the DB instances in the DB cluster immediately without a reboot. Changes to other parameters are applied only after the DB instances in the DB cluster are rebooted.

Setting and description	Method	Scope	Downtime notes
DB instance class The DB instance class that you want to use. For more information, see Aurora DB instance classes (p. 54) .	Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373) . Using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--db-instance-class</code> option. Using the RDS API, call ModifyDBInstance and set the <code>DBInstanceClass</code> parameter.	Only the specified DB instance	An outage occurs during this change.
DB instance identifier The DB instance identifier. This value is stored as a lowercase string.	Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373) . Using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--new-db-instance-identifier</code> option. Using the RDS API, call ModifyDBInstance and set the <code>NewDBInstanceIdentifier</code> parameter.	Only the specified DB instance	An outage occurs during this change. The DB instance is rebooted.

Setting and description	Method	Scope	Downtime notes
DB parameter group The DB parameter group that you want associated with the DB instance. For more information, see Working with DB parameter groups and DB cluster parameter groups (p. 339) .	Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373) . Using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--db-parameter-group-name</code> option. Using the RDS API, call ModifyDBInstance and set the <code>DBParameterGroupName</code> parameter.	Only the specified DB instance	An outage doesn't occur during this change. When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the newly associated DB parameter group, these changes are applied immediately without a reboot. For more information, see Working with DB parameter groups and DB cluster parameter groups (p. 339) and Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance (p. 451) .
Deletion protection Enable deletion protection to prevent your DB cluster from being deleted. For more information, see Deletion protection for Aurora clusters (p. 471) .	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--deletion-protection --no-deletion-protection</code> option. Using the RDS API, call ModifyDBCluster and set the <code>DeletionProtection</code> parameter.	The entire DB cluster	An outage doesn't occur during this change.

Setting and description	Method	Scope	Downtime notes
Engine version The version of the DB engine that you want to use. Before you upgrade your production DB cluster, we recommend that you test the upgrade process on a test DB cluster to verify its duration and to validate your applications.	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--engine-version</code> option. Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>EngineVersion</code> parameter.	The entire DB cluster	An outage occurs during this change.
Enhanced monitoring Enable enhanced monitoring to enable gathering metrics in real time for the operating system that your DB instance runs on. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 626) .	Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373) . Using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--monitoring-role-arn</code> and <code>--monitoring-interval</code> options. Using the RDS API, call <code>ModifyDBInstance</code> and set the <code>MonitoringRoleArn</code> and <code>MonitoringInterval</code> parameters.	Only the specified DB instance	An outage doesn't occur during this change.

Setting and description	Method	Scope	Downtime notes
<p>Log exports</p> <p>Select the log types to publish to Amazon CloudWatch Logs.</p> <p>For more information, see Aurora MySQL database log files (p. 700).</p>	<p>Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372).</p> <p>Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--cloudwatch-logs-export-configuration</code> option.</p> <p>Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>CloudwatchLogsExportConfiguration</code> parameter.</p>	The entire DB cluster	An outage doesn't occur during this change.

Setting and description	Method	Scope	Downtime notes
<p>Maintenance window</p> <p>The time range during which system maintenance occurs. System maintenance includes upgrades, if applicable. The maintenance window is a start time in Universal Coordinated Time (UTC), and a duration in hours.</p> <p>If you set the window to the current time, there must be at least 30 minutes between the current time and end of the window to ensure any pending changes are applied.</p> <p>You can set the maintenance window independently for the DB cluster and for each DB instance in the DB cluster. When the scope of a modification is the entire DB cluster, the modification is performed during the DB cluster maintenance window. When the scope of a modification is the a DB instance, the modification is performed during maintenance window of that DB instance.</p> <p>The maintenance window and the backup window for the DB cluster can't overlap.</p> <p>For more information, see The Amazon RDS maintenance window (p. 446).</p>	<p>To change the maintenance window for the DB cluster using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372).</p> <p>To change the maintenance window for a DB instance using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373).</p> <p>To change the maintenance window for the DB cluster using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--preferred-maintenance-window</code> option.</p> <p>To change the maintenance window for a DB instance using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--preferred-maintenance-window</code> option.</p> <p>To change the maintenance window for the DB cluster using the RDS API, call ModifyDBCluster and set the <code>PreferredMaintenanceWindow</code> parameter.</p> <p>To change the maintenance window for a DB instance using the RDS API, call ModifyDBInstance and set the <code>PreferredMaintenanceWindow</code> parameter.</p>	<p>The entire DB cluster or a single DB instance</p>	<p>If there are one or more pending actions that cause an outage, and the maintenance window is changed to include the current time, then those pending actions are applied immediately, and an outage occurs.</p>

Setting and description	Method	Scope	Downtime notes
New master password The password for your master user. The password must contain from 8 to 41 alphanumeric characters.	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--master-user-password</code> option. Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>MasterUserPassword</code> parameter.	The entire DB cluster	An outage doesn't occur during this change.
Performance Insights Whether to enable Performance Insights, a tool that monitors your DB instance load so that you can analyze and troubleshoot your database performance. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 573) .	Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373) . Using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--enable-performance-insights --no-enable-performance-insights</code> option. Using the RDS API, call <code>ModifyDBInstance</code> and set the <code>EnablePerformanceInsights</code> parameter.	Only the specified DB instance	An outage doesn't occur during this change.

Setting and description	Method	Scope	Downtime notes
Performance Insights AWS KMS key The AWS KMS key identifier for encryption of Performance Insights data. The KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the KMS key. For more information, see Enabling and disabling Performance Insights (p. 577) .	Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373) . Using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--performance-insights-kms-key-id</code> option. Using the RDS API, call <code>ModifyDBInstance</code> and set the <code>PerformanceInsightsKMSKeyId</code> parameter.	Only the specified DB instance	An outage doesn't occur during this change.
Performance Insights retention period The amount of time, in days, to retain Performance Insights data. Valid values are 7 or 731 (2 years). For more information, see Enabling and disabling Performance Insights (p. 577) .	Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373) . Using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--performance-insights-retention-period</code> option. Using the RDS API, call <code>ModifyDBInstance</code> and set the <code>PerformanceInsightsRetentionPeriod</code> parameter.	Only the specified DB instance	An outage doesn't occur during this change.
Promotion tier A value that specifies the order in which an Aurora Replica is promoted to the primary instance in a cluster that uses single-master replication, after a failure of the existing primary instance. For more information, see Fault tolerance for an Aurora DB cluster (p. 69) .	Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373) . Using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--promotion-tier</code> option. Using the RDS API, call <code>ModifyDBInstance</code> and set the <code>PromotionTier</code> parameter.	Only the specified DB instance	An outage doesn't occur during this change.

Setting and description	Method	Scope	Downtime notes
<p>Public access</p> <p>Publicly accessible to give the DB instance a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB instance also has to be in a public subnet in the VPC.</p> <p>Not publicly accessible to make the DB instance accessible only from inside the VPC.</p> <p>For more information, see Hiding a DB instance in a VPC from the internet (p. 1789).</p> <p>To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 1814).</p> <p>If your DB instance is isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 1723).</p>	<p>Using the AWS Management Console, Modify a DB instance in a DB cluster (p. 373).</p> <p>Using the AWS CLI, run <code>modify-db-instance</code> and set the <code>--publicly-accessible --no-publicly-accessible</code> option.</p> <p>Using the RDS API, call ModifyDBInstance and set the <code>PubliclyAccessible</code> parameter.</p>	Only the specified DB instance	An outage doesn't occur during this change.

Setting and description	Method	Scope	Downtime notes
Scaling configuration The scaling properties of the DB cluster. You can only modify scaling properties for DB clusters in serverless DB engine mode. This setting is available only for Aurora MySQL. For information about Aurora Serverless, see Using Amazon Aurora Serverless v1 (p. 147) .	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--scaling-configuration</code> option. Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>ScalingConfiguration</code> parameter.	The entire DB cluster	An outage doesn't occur during this change.
Security group The security group you want associated with the DB cluster. For more information, see Controlling access with security groups (p. 1780) .	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--vpc-security-group-ids</code> option. Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>VpcSecurityGroupIds</code> parameter.	The entire DB cluster	An outage doesn't occur during this change.

Setting and description	Method	Scope	Downtime notes
Target Backtrack window The amount of time you want to be able to backtrack your DB cluster, in seconds. This setting is available only for Aurora MySQL and only if the DB cluster was created with Backtrack enabled.	Using the AWS Management Console, Modifying the DB cluster by using the console, CLI, and API (p. 372) . Using the AWS CLI, run <code>modify-db-cluster</code> and set the <code>--backtrack-window</code> option. Using the RDS API, call <code>ModifyDBCluster</code> and set the <code>BacktrackWindow</code> parameter.	The entire DB cluster	An outage doesn't occur during this change.

Settings that do not apply to Amazon Aurora

The following settings in the AWS CLI command `modify-db-instance` and the RDS API operation [`ModifyDBInstance`](#) do not apply to Amazon Aurora.

Note

The AWS Management Console doesn't allow you to modify these settings for Aurora.

AWS CLI setting	RDS API setting
<code>--allocated-storage</code>	<code>AllocatedStorage</code>
<code>--allow-major-version-upgrade --no-allow-major-version-upgrade</code>	<code>AllowMajorVersionUpgrade</code>
<code>--copy-tags-to-snapshot --no-copy-tags-to-snapshot</code>	<code>CopyTagsToSnapshot</code>
<code>--domain</code>	<code>Domain</code>
<code>--db-security-groups</code>	<code>DBSecurityGroups</code>
<code>--db-subnet-group-name</code>	<code>DBSubnetGroupName</code>
<code>--domain-iam-role-name</code>	<code>DomainIAMRoleName</code>
<code>--multi-az --no-multi-az</code>	<code>MultiAZ</code>
<code>--iops</code>	<code>Iops</code>
<code>--license-model</code>	<code>LicenseModel</code>
<code>--option-group-name</code>	<code>OptionGroupName</code>
<code>--processor-features</code>	<code>ProcessorFeatures</code>

AWS CLI setting	RDS API setting
--storage-type	StorageType
--tde-credential-arn	TdeCredentialArn
--tde-credential-password	TdeCredentialPassword
--use-default-processor-features --no-use-default-processor-features	UseDefaultProcessorFeatures

Adding Aurora Replicas to a DB cluster

An Aurora DB cluster with single-master replication has one primary DB instance and up to 15 Aurora Replicas. The primary DB instance supports read and write operations, and performs all data modifications to the cluster volume. Aurora Replicas connect to the same storage volume as the primary DB instance, but support read operations only. You use Aurora Replicas to offload read workloads from the primary DB instance. For more information, see [Aurora Replicas \(p. 70\)](#).

Amazon Aurora Replicas have the following limitations:

- You can't create an Aurora Replica for an Aurora Serverless v1 DB cluster. Aurora Serverless v1 has a single DB instance that scales up and down automatically to support all database read and write operations.
- You can't create Aurora Replicas for an Aurora multi-master cluster. By design, an Aurora multi-master cluster has read-write DB instances only.

We recommend that you distribute the primary instance and Aurora Replicas of your Aurora DB cluster over multiple Availability Zones to improve the availability of your DB cluster. For more information, see [Region availability \(p. 12\)](#).

To remove an Aurora Replica from an Aurora DB cluster, delete the Aurora Replica by following the instructions in [Deleting a DB instance from an Aurora DB cluster \(p. 472\)](#).

Note

Amazon Aurora also supports replication with an external database, such as an RDS DB instance. The RDS DB instance must be in the same AWS Region as Amazon Aurora. For more information, see [Replication with Amazon Aurora \(p. 70\)](#).

You can add Aurora Replicas to a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To add an Aurora replica to a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then select the DB cluster where you want to add the new DB instance.
3. Make sure that both the cluster and the primary instance are in the **Available** state. If the DB cluster or the primary instance are in a transitional state such as **Creating**, you can't add a replica.

If the cluster doesn't have a primary instance, create one using the `create-db-instance` AWS CLI command. This situation can arise if you used the CLI to restore a DB cluster snapshot and then view the cluster in the AWS Management Console.

4. For **Actions**, choose **Add reader**.

The **Add reader** page appears.

5. On the **Add reader** page, specify options for your Aurora Replica. The following table shows settings for an Aurora Replica.

For this option	Do this
Availability zone	Determine if you want to specify a particular Availability Zone. The list includes only those Availability Zones

For this option	Do this
	that are mapped by the DB subnet group you specified earlier. For more information about Availability Zones, see Regions and Availability Zones (p. 11) .
Publicly accessible	Select Yes to give the Aurora Replica a public IP address; otherwise, select No. For more information about hiding Aurora Replicas from public access, see Hiding a DB instance in a VPC from the internet (p. 1789) .
Encryption	Select Enable encryption to enable encryption at rest for this Aurora Replica. For more information, see Encrypting Amazon Aurora resources (p. 1709) .
DB instance class	Select a DB instance class that defines the processing and memory requirements for the Aurora Replica. For more information about DB instance class options, see Aurora DB instance classes (p. 54) .
Aurora replica source	Select the identifier of the primary instance to create an Aurora Replica for.
DB instance identifier	Enter a name for the instance that is unique for your account in the AWS Region you selected. You might choose to add some intelligence to the name such as including the AWS Region and DB engine you selected, for example aurora-read-instance1 .
Priority	Choose a failover priority for the instance. If you don't select a value, the default is tier-1 . This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. For more information, see Fault tolerance for an Aurora DB cluster (p. 69) .
Database port	The port for an Aurora Replica is the same as the port for the DB cluster.
DB parameter group	Select a parameter group. Aurora has a default parameter group you can use, or you can create your own parameter group. For more information about parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 339) .
Enhanced monitoring	Choose Enable enhanced monitoring to enable gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 626) .
Monitoring Role	Only available if Enhanced Monitoring is set to Enable enhanced monitoring . Choose the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose Default to have RDS create a role for you named <code>rds-monitoring-role</code> . For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 626) .

For this option	Do this
Granularity	Only available if Enhanced Monitoring is set to Enable enhanced monitoring . Set the interval, in seconds, between when metrics are collected for your DB cluster.
Auto minor version upgrade	<p>Select Enable auto minor version upgrade if you want to enable your Aurora DB cluster to receive minor DB Engine version upgrades automatically when they become available.</p> <p>The Auto minor version upgrade setting applies to both Aurora PostgreSQL and Aurora MySQL DB clusters. For Aurora MySQL 1.x and 2.x clusters, this setting upgrades the clusters to a maximum version of 1.22.2 and 2.07.2.</p> <p>For more information about engine updates for Aurora PostgreSQL, see Amazon Aurora PostgreSQL updates (p. 1597).</p> <p>For more information about engine updates for Aurora MySQL, see Database engine updates for Amazon Aurora MySQL (p. 1082).</p>

6. Choose **Add reader** to create the Aurora Replica.

AWS CLI

To create an Aurora Replica in your DB cluster, run the [create-db-instance](#) AWS CLI command. Include the name of the DB cluster as the `--db-cluster-identifier` option. You can optionally specify an Availability Zone for the Aurora Replica using the `--availability-zone` parameter, as shown in the following examples.

For example, the following command creates a new MySQL 5.7-compatible Aurora Replica named `sample-instance-us-west-2a`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a \
    --db-cluster-identifier sample-cluster --engine aurora-mysql --db-instance-class
    db.r5.large \
    --availability-zone us-west-2a
```

For Windows:

```
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a ^
    --db-cluster-identifier sample-cluster --engine aurora-mysql --db-instance-class
    db.r5.large ^
    --availability-zone us-west-2a
```

The following command creates a new MySQL 5.6-compatible Aurora Replica named `sample-instance-us-west-2a`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a \
    --db-cluster-identifier sample-cluster --engine aurora --db-instance-class db.r5.large \
    \
```

```
--availability-zone us-west-2a
```

For Windows:

```
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a ^
--db-cluster-identifier sample-cluster --engine aurora --db-instance-class db.r5.large
^
--availability-zone us-west-2a
```

The following command creates a new PostgreSQL-compatible Aurora Replica named `sample-instance-us-west-2a`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a \
--db-cluster-identifier sample-cluster --engine aurora-postgresql --db-instance-class
db.r5.large \
--availability-zone us-west-2a
```

For Windows:

```
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a ^
--db-cluster-identifier sample-cluster --engine aurora-postgresql --db-instance-class
db.r5.large ^
--availability-zone us-west-2a
```

RDS API

To create an Aurora Replica in your DB cluster, call the [CreateDBInstance](#) operation. Include the name of the DB cluster as the `DBClusterIdentifier` parameter. You can optionally specify an Availability Zone for the Aurora Replica using the `AvailabilityZone` parameter.

Managing performance and scaling for Aurora DB clusters

You can use the following options to manage performance and scaling for Aurora DB clusters and DB instances:

Topics

- [Storage scaling \(p. 396\)](#)
- [Instance scaling \(p. 400\)](#)
- [Read scaling \(p. 400\)](#)
- [Managing connections \(p. 400\)](#)
- [Managing query execution plans \(p. 401\)](#)

Storage scaling

Aurora storage automatically scales with the data in your cluster volume. As your data grows, your cluster volume storage expands up to a maximum of 128 tebibytes (TiB) or 64 TiB. The maximum size depends on the DB engine version. To learn what kinds of data are included in the cluster volume, see [Amazon Aurora storage and reliability \(p. 64\)](#). For details about the maximum size for a specific version, see [Amazon Aurora size limits \(p. 1813\)](#).

The size of your cluster volume is evaluated on an hourly basis to determine your storage costs. For pricing information, see the [Aurora pricing page](#).

Even though an Aurora cluster volume can scale up in size to many tebibytes, you are only charged for the space that you use in the volume. The mechanism for determining billed storage space depends on the version of your Aurora cluster.

- When Aurora data is removed from the cluster volume, the overall billed space decreases by a comparable amount. This dynamic resizing behavior happens when underlying database files are deleted or reorganized to require less space. Thus, you can reduce storage charges by deleting tables, indexes, databases, and so on that you no longer need. Dynamic resizing applies to certain Aurora versions. The following are the Aurora versions where the cluster volume dynamically resizes as you delete data:
 - Aurora MySQL 3 (compatible with MySQL 8.0), all minor versions
 - Aurora MySQL 2.09 (compatible with MySQL 5.7) and higher
 - Aurora MySQL version 1.23 (compatible with MySQL 5.6) and higher
 - All Aurora PostgreSQL 13 versions
 - Aurora PostgreSQL version 12.4 and higher
 - Aurora PostgreSQL version 11.8 and higher
 - Aurora PostgreSQL version 10.13 and higher
- In Aurora versions lower than those in the preceding list, the cluster volume can reuse space that was freed up when you deleted data, but the volume itself never decreases in size.
- This feature is being deployed in phases to the AWS Regions where Aurora is available. Depending on the Region where your cluster is, this feature might not be available yet.

Dynamic resizing applies to operations that physically remove or resize data files within the cluster volume. Thus, it applies to SQL statements such as `DROP TABLE`, `DROP DATABASE`, `TRUNCATE TABLE`, and `ALTER TABLE ... DROP PARTITION`. It doesn't apply to deleting rows using the `DELETE` statement. If you delete a large number of rows from a table, you can run the Aurora MySQL `OPTIMIZE`

TABLE statement or use the Aurora PostgreSQL pg_repack extension afterward to reorganize the table and dynamically resize the cluster volume.

Note

For Aurora MySQL, the innodb_file_per_table affects how table storage is organized.

When tables are part of the system tablespace, dropping the table doesn't reduce the size of the system tablespace. Thus, make sure to use the setting innodb_file_per_table=1 for Aurora MySQL clusters to take full advantage of dynamic resizing.

These Aurora versions also have a higher storage limit for the cluster volume than lower versions do. Thus, you can consider upgrading to one of these versions if you are close to exceeding the original 64 TiB volume size.

You can check how much storage space a cluster is using by monitoring the VolumeBytesUsed metric in CloudWatch.

- In the AWS Management Console, you can see this figure in a chart by viewing the Monitoring tab on the details page for the cluster.
- With the AWS CLI, you can run a command similar to the following Linux example. Substitute your own values for the start and end times and the name of the cluster.

```
aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" \
--start-time "$(date -d '6 hours ago')" --end-time "$(date -d 'now')" --period 60 \
--namespace "AWS/RDS" \
--statistics Average Maximum Minimum \
--dimensions Name=DBClusterIdentifier,Value=my_cluster_identifier
```

That command produces output similar to the following.

```
{  
    "Label": "VolumeBytesUsed",  
    "Datapoints": [  
        {  
            "Timestamp": "2020-08-04T21:25:00+00:00",  
            "Average": 182871982080.0,  
            "Minimum": 182871982080.0,  
            "Maximum": 182871982080.0,  
            "Unit": "Bytes"  
        }  
    ]  
}
```

The following examples show how you might track storage usage for an Aurora cluster over time using AWS CLI commands on a Linux system. The --start-time and --end-time parameters define the overall time interval as one day. The --period parameter requests the measurements at one hour intervals. It doesn't make sense to choose a --period value that's small, because the metrics are collected at intervals, not continuously. Also, Aurora storage operations sometimes continue for some time in the background after the relevant SQL statement finishes.

The first example returns output in the default JSON format. The data points are returned in arbitrary order, not sorted by timestamp. You might import this JSON data into a charting tool to do sorting and visualization.

```
$ aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" \
--start-time "$(date -d '1 day ago')" --end-time "$(date -d 'now')" --period 3600
--namespace "AWS/RDS" --statistics Maximum --dimensions
Name=DBClusterIdentifier,Value=my_cluster_id
{  
    "Label": "VolumeBytesUsed",
```

```

    "Datapoints": [
      {
        "Timestamp": "2020-08-04T19:40:00+00:00",
        "Maximum": 182872522752.0,
        "Unit": "Bytes"
      },
      {
        "Timestamp": "2020-08-05T00:40:00+00:00",
        "Maximum": 198573719552.0,
        "Unit": "Bytes"
      },
      {
        "Timestamp": "2020-08-05T05:40:00+00:00",
        "Maximum": 206827454464.0,
        "Unit": "Bytes"
      },
      {
        "Timestamp": "2020-08-04T17:40:00+00:00",
        "Maximum": 182872522752.0,
        "Unit": "Bytes"
      },
      ...
    ... output omitted ...
  
```

This example returns the same data as the previous one. The `--output` parameter represents the data in compact plain text format. The `aws cloudwatch` command pipes its output to the `sort` command. The `-k` parameter of the `sort` command sorts the output by the third field, which is the timestamp in Universal Coordinated Time (UTC) format.

```

$ aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" \
--start-time "$(date -d '1 day ago')" --end-time "$(date -d 'now')" --period 3600 \
--namespace "AWS/RDS" --statistics Maximum --dimensions \
Name=DBClusterIdentifier,Value=my_cluster_id \
--output text | sort -k 3

```

The sorted output shows how much storage was used at the start and end of the monitoring period. You can also find the points during that period when Aurora allocated more storage for the cluster. The following example uses Linux commands to reformat the starting and ending `VolumeBytesUsed` values as gigabytes (GB) and as gibibytes (GiB). Gigabytes represent units measured in powers of 10 and are

commonly used in discussions of storage for rotational hard drives. Gibibytes represent units measured in powers of 2. Aurora storage measurements and limits are typically stated in the power-of-2 units, such as gibibytes and tebibytes.

```
$ GiB=$((1024*1024*1024))
$ GB=$((1000*1000*1000))
$ echo "Start: $((182872522752/$GiB)) GiB, End: $((206833664000/$GiB)) GiB"
Start: 170 GiB, End: 192 GiB
$ echo "Start: $((182872522752/$GB)) GB, End: $((206833664000/$GB)) GB"
Start: 182 GB, End: 206 GB
```

The `VolumeBytesUsed` metric tells you how much storage in the cluster is incurring charges. Thus, it's best to minimize this number when practical. However, this metric doesn't include some storage that Aurora uses internally in the cluster and doesn't charge for. If your cluster is approaching the storage limit and might run out of space, it's more helpful to monitor the `AuroraVolumeBytesLeftTotal` metric and try to maximize that number. The following example runs a similar calculation as the previous one, but for `AuroraVolumeBytesLeftTotal` instead of `VolumeBytesUsed`. You can see that the free size for this cluster reflects the original 64 TiB limit, because the cluster is running Aurora MySQL version 1.22.

```
$ aws cloudwatch get-metric-statistics --metric-name "AuroraVolumeBytesLeftTotal" \
--start-time "$($date -d '1 hour ago')" --end-time "$($date -d 'now')" --period 3600 \
--namespace "AWS/RDS" --statistics Maximum --dimensions
Name=DBClusterIdentifier,Value=my_old_cluster_id \
--output text | sort -k 3
AuroraVolumeBytesLeftTotal
DATAPOINTS      69797193744384.0      2020-08-05T17:52:00+00:00      Count
DATAPOINTS      69797193744384.0      2020-08-05T18:52:00+00:00      Count
$ TiB=$((1024*1024*1024*1024))
$ TB=$((1000*1000*1000*1000))
$ echo "$((69797067915264 / $TB)) TB remaining for this cluster"
69 TB remaining for this cluster
$ echo "$((69797067915264 / $TiB)) TiB remaining for this cluster"
63 TiB remaining for this cluster
```

For a cluster running Aurora MySQL version 1.23 or 2.09 and higher, or Aurora PostgreSQL 3.3.0 or 2.6.0 and higher, the free size reported by `VolumeBytesUsed` increases when data is added and decreases when data is removed. The following example shows how. This report shows the maximum and minimum storage size for a cluster at 15-minute intervals as tables with temporary data are created and dropped. The report lists the maximum value before the minimum value. Thus, to understand how storage usage changed within the 15-minute interval, interpret the numbers from right to left.

```
$ aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" \
--start-time "$($date -d '4 hours ago')" --end-time "$($date -d 'now')" --period 1800 \
--namespace "AWS/RDS" --statistics Maximum Minimum --dimensions

127 TiB remaining for this cluster
```

Instance scaling

You can scale your Aurora DB cluster as needed by modifying the DB instance class for each DB instance in the DB cluster. Aurora supports several DB instance classes optimized for Aurora, depending on database engine compatibility.

Database engine	Instance scaling
Amazon Aurora MySQL	See Scaling Aurora MySQL DB instances (p. 812)
Amazon Aurora PostgreSQL	See Scaling Aurora PostgreSQL DB instances (p. 1360)

Read scaling

You can achieve read scaling for your Aurora DB cluster by creating up to 15 Aurora Replicas in a DB cluster that uses single-master replication. Each Aurora Replica returns the same data from the cluster volume with minimal replica lag—usually considerably less than 100 milliseconds after the primary instance has written an update. As your read traffic increases, you can create additional Aurora Replicas and connect to them directly to distribute the read load for your DB cluster. Aurora Replicas don't have to be of the same DB instance class as the primary instance.

For information about adding Aurora Replicas to a DB cluster, see [Adding Aurora Replicas to a DB cluster \(p. 392\)](#).

Managing connections

The maximum number of connections allowed to an Aurora DB instance is determined by the `max_connections` parameter in the instance-level parameter group for the DB instance. The default value of that parameter varies depends on the DB instance class used for the DB instance and database engine compatibility.

Database engine	max_connections default value
Amazon Aurora MySQL	See Maximum connections to an Aurora MySQL DB instance (p. 813)
Amazon Aurora PostgreSQL	See Maximum connections to an Aurora PostgreSQL DB instance (p. 1360)

If your applications frequently open and close connections, or have long-lived connections that approach or exceed the specified limits, we recommend using Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see [Using Amazon RDS Proxy \(p. 288\)](#).

Managing query execution plans

If you use query plan management for Aurora PostgreSQL, you gain control over which plans the optimizer runs. For more information, see [Managing query execution plans for Aurora PostgreSQL \(p. 1460\)](#).

Cloning a volume for an Aurora DB cluster

By using Aurora cloning, you can quickly and cost-effectively create a new cluster that uses the same Aurora cluster volume and has the same data as the original. The new cluster with its associated data volume is known as a *clone*. Creating a clone is faster and more space-efficient than physically copying the data using other techniques, such as restoring a snapshot.

Aurora supports many different types of cloning. You can create an Aurora provisioned clone from a provisioned Aurora DB cluster. You can create an Aurora Serverless v1 clone from an Aurora Serverless v1 DB cluster. But you can also create Aurora Serverless v1 clones from Aurora provisioned DB clusters, and you can create provisioned clones from Aurora Serverless v1 DB clusters. When you create a clone using a different deployment configuration than the source, the clone is created using the latest minor version of the source's Aurora DB engine.

A cloned Aurora Serverless DB cluster has the same behavior and limitations as any Aurora Serverless v1 DB cluster. For more information, see [Using Amazon Aurora Serverless v1 \(p. 147\)](#).

When you create clones from your Aurora DB clusters, the clones are created in your AWS account—the same account that owns the source Aurora DB cluster. However, you can also share provisioned Aurora DB clusters and clones with other AWS accounts. For more information, see [Cross-account cloning with AWS RAM and Amazon Aurora \(p. 415\)](#).

Cross-account cloning currently doesn't support cloning Aurora Serverless v1 DB clusters. For more information, see [Limitations of cross-account cloning \(p. 415\)](#).

Topics

- [Overview of Aurora cloning \(p. 402\)](#)
- [Limitations of Aurora cloning \(p. 403\)](#)
- [How Aurora cloning works \(p. 403\)](#)
- [Creating an Amazon Aurora clone \(p. 406\)](#)
- [Cross-account cloning with AWS RAM and Amazon Aurora \(p. 415\)](#)

Overview of Aurora cloning

Aurora uses a *copy-on-write protocol* to create a clone. This mechanism uses minimal additional space to create an initial clone. When the clone is first created, Aurora keeps a single copy of the data that is used by the source Aurora DB cluster and the new (cloned) Aurora DB cluster. Additional storage is allocated only when changes are made to data (on the Aurora storage volume) by the source Aurora DB cluster or the Aurora DB cluster clone. To learn more about the copy-on-write protocol, see [How Aurora cloning works \(p. 403\)](#).

Aurora cloning is especially useful for quickly setting up test environments using your production data, without risking data corruption. You can use clones for many types of applications, such as the following:

- Experiment with potential changes (schema changes and parameter group changes, for example) to assess all impacts.
- Run workload-intensive operations, such as exporting data or running analytical queries on the clone.
- Create a copy of your production DB cluster for development, testing, or other purposes.

You can create more than one clone from the same Aurora DB cluster. You can also create multiple clones from another clone.

After creating an Aurora clone, you can configure the Aurora DB instances differently from the source Aurora DB cluster. For example, you might not need a clone for development purposes to meet the same

high availability requirements as the source production Aurora DB cluster. In this case, you can configure the clone with a single Aurora DB instance rather than the multiple DB instances used by the Aurora DB cluster.

When you finish using the clone for your testing, development, or other purposes, you can delete it.

Limitations of Aurora cloning

Aurora cloning currently has the following limitations:

- You can't create a clone in a different AWS Region than the source Aurora DB cluster.
- You can't create an Aurora Serverless v1 clone from a nonencrypted provisioned Aurora DB cluster.
- You can't create a Aurora Serverless v1 clone from a MySQL 5.6-compatible provisioned cluster, or a provisioned clone of a MySQL 5.6-compatible Aurora Serverless v1 cluster.
- You can't create more than 15 clones based on a copy or based on another clone. After creating 15 clones, you can create copies only. However, you can create up to 15 clones of each copy.
- You can't create a clone from an Aurora DB cluster without the parallel query feature to a cluster that uses parallel query. To bring data into a cluster that uses parallel query, create a snapshot of the original cluster and restore it to the cluster that's using the parallel query feature.
- You can't create a clone from an Aurora DB cluster that has no DB instances. You can only clone Aurora DB clusters that have at least one DB instance.
- You can create a clone in a different virtual private cloud (VPC) than that of the Aurora DB cluster. If you do, the subnets of the VPCs must map to the same Availability Zones.

How Aurora cloning works

Aurora cloning works at the storage layer of an Aurora DB cluster. It uses a *copy-on-write* protocol that's both fast and space-efficient in terms of the underlying durable media supporting the Aurora storage volume. You can learn more about Aurora cluster volumes in the [Overview of Aurora storage \(p. 64\)](#).

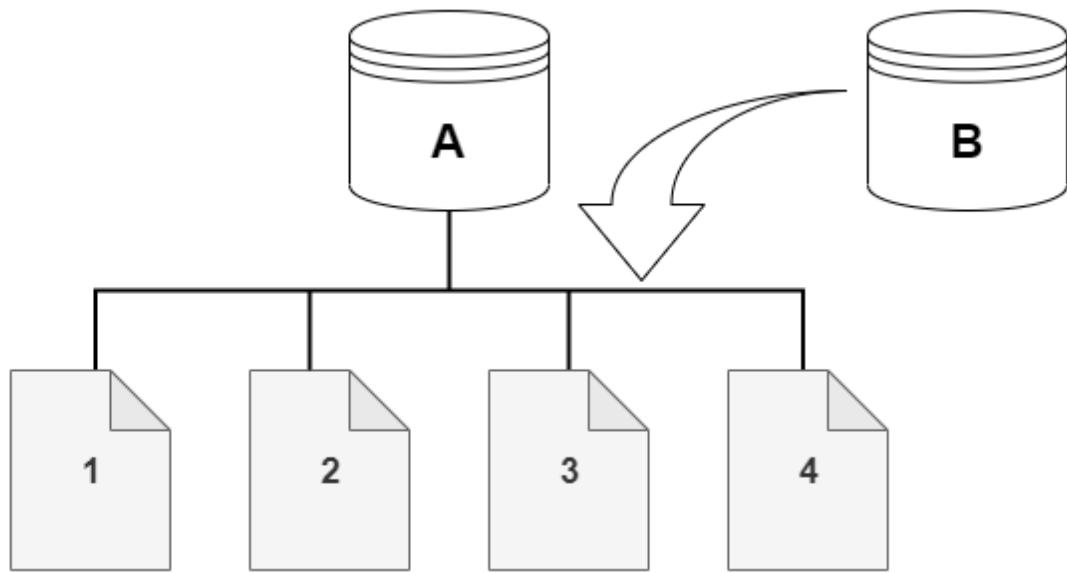

Topics

- [Understanding the copy-on-write protocol \(p. 403\)](#)
- [Deleting a source cluster volume \(p. 406\)](#)

Understanding the copy-on-write protocol

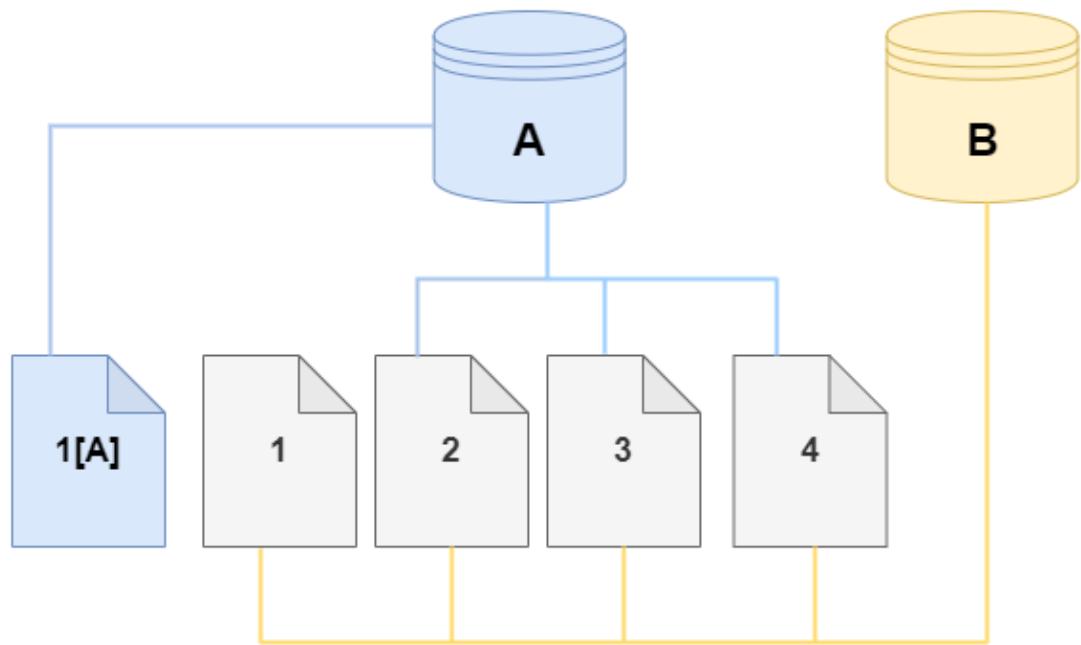

An Aurora DB cluster stores data in pages in the underlying Aurora storage volume.

For example, in the following diagram you can find an Aurora DB cluster (A) that has four data pages, 1, 2, 3, and 4. Imagine that a clone, B, is created from the Aurora DB cluster. When the clone is created, no data is copied. Rather, the clone points to the same set of pages as the source Aurora DB cluster.

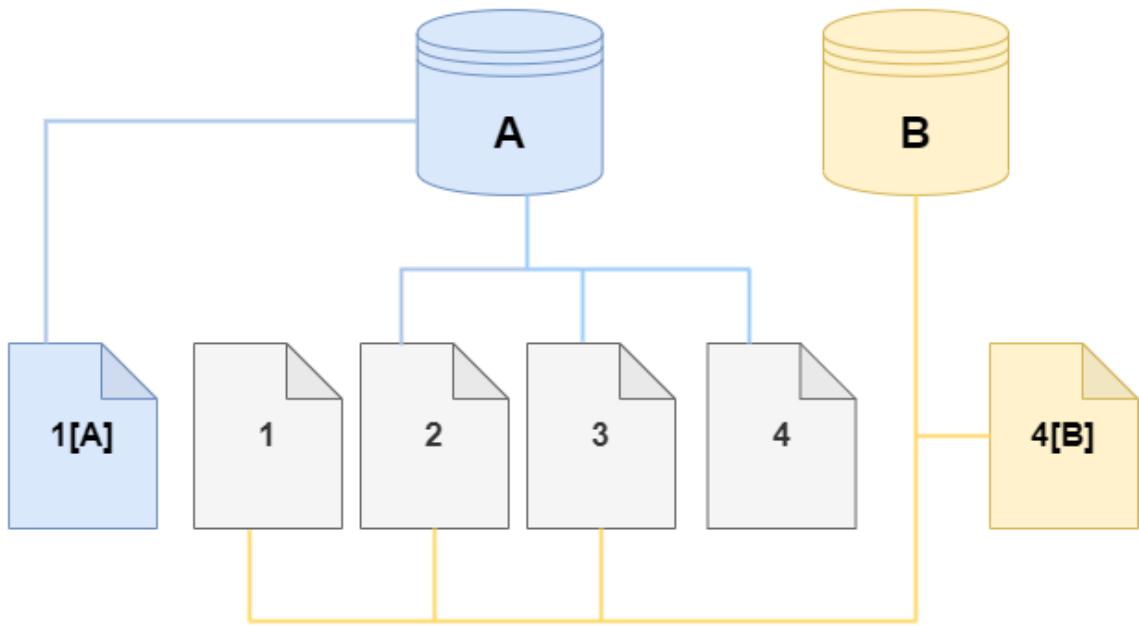

When the clone is created, no additional storage is usually needed. The copy-on-write protocol uses the same segment on the physical storage media as the source segment. Additional storage is required only if the capacity of the source segment isn't sufficient for the entire clone segment. If that's the case, the source segment is copied to another physical device.

In the following diagrams, you can find an example of the copy-on-write protocol in action using the same cluster A and its clone, B, as shown preceding. Let's say that you make a change to your Aurora DB cluster (A) that results in a change to data held on page 1. Instead of writing to the original page 1, Aurora creates a new page 1[A]. The Aurora DB cluster volume for cluster (A) now points to page 1[A], 2, 3, and 4, while the clone (B) still references the original pages.

On the clone, a change is made to page 4 on the storage volume. Instead of writing to the original page 4, Aurora creates a new page, 4[B]. The clone now points to pages 1, 2, 3, and to page 4[B], while the cluster (A) continues pointing to 1[A], 2, 3, and 4.

As more changes occur over time in both the source Aurora DB cluster volume and the clone, more storage is needed to capture and store the changes.

Deleting a source cluster volume

When you delete a source cluster volume that has one or more clones associated with it, the clones aren't affected. The clones continue to point to the pages that were previously owned by the source cluster volume.

Creating an Amazon Aurora clone

You can create a clone in the same AWS account as the source Aurora DB cluster. To do so, you can use the AWS Management Console or the AWS CLI and the procedures following.

To allow another AWS account to create a clone or to share a clone with another AWS account, use the procedures in [Cross-account cloning with AWS RAM and Amazon Aurora \(p. 415\)](#).

By using Aurora cloning, you can do the following types of cloning operations:

- Create a provisioned Aurora DB cluster clone from a provisioned Aurora DB cluster.
- Create an Aurora Serverless v1 cluster clone from an Aurora Serverless v1 DB cluster.
- Create an Aurora Serverless v1 DB cluster clone from a provisioned Aurora DB cluster.
- Create an Aurora provisioned DB cluster clone from an Aurora Serverless v1 DB cluster.

Aurora Serverless v1 DB clusters are always encrypted. When you clone an Aurora Serverless v1 DB cluster into a provisioned Aurora DB cluster, the provisioned Aurora DB cluster is encrypted. You can

choose the encryption key, but you can't disable the encryption. To clone from a provisioned Aurora DB cluster to an Aurora Serverless v1 cluster, you need an encrypted provisioned Aurora DB cluster.

Console

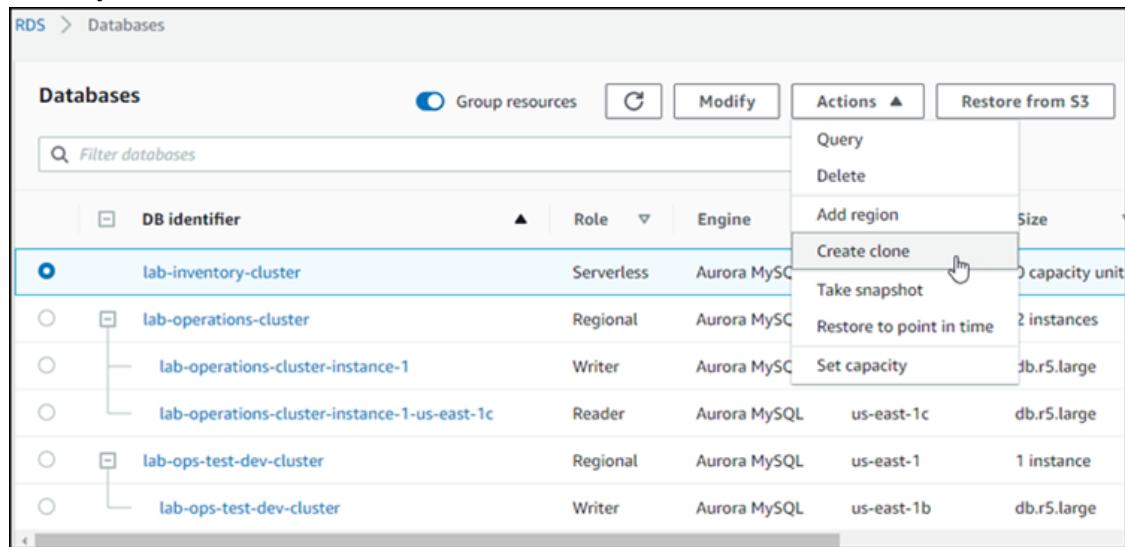

The following procedure describes how to clone an Aurora DB cluster using the AWS Management Console.

Creating a clone using the AWS Management Console results in an Aurora DB cluster with one Aurora DB instance.

These instructions apply for DB clusters owned by the same AWS account that is creating the clone. If the DB cluster is owned by a different AWS account, see [Cross-account cloning with AWS RAM and Amazon Aurora \(p. 415\)](#) instead.

To create a clone of a DB cluster owned by your AWS account using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose your Aurora DB cluster from the list, and for **Actions**, choose **Create clone**.

The Create clone page opens, where you can configure **Instance specifications**, **Connectivity**, and other options for the Aurora DB cluster clone.

4. In the **Instance specifications** section, do the following:
 - a. For **DB cluster identifier**, enter the name that you want to give to your cloned Aurora DB cluster.

Instance specifications

DB engine

Aurora MySQL

Source DB instance [Info](#)

lab-inventory-cluster

DB instance identifier [Info](#)

Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

lab-inventory-audit-cluster

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens (1 to 15 for SQL Server). First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Capacity type [Info](#)

Provisioned

You provision and manage the server instance sizes.

Serverless

You specify the minimum and maximum amount of resources needed, and Aurora scales the capacity based on database load. This is a good option for intermittent or unpredictable workloads.

- b. For **Capacity type**, choose **Provisioned** or **Serverless** as needed for your use case.

You can choose **Serverless** only if the source Aurora DB cluster is an Aurora Serverless v1 DB cluster or is a provisioned Aurora DB cluster that is encrypted.

- If you choose **Provisioned**, you see a **DB instance size** configuration card.

DB instance size

DB instance class [Info](#)

Choose a DB instance class that meets your processing power and memory requirements. The DB instance class options below are limited to those supported by the engine you selected above.

Memory Optimized classes (includes r classes)

Burstable classes (includes t classes)

db.r5.large

2 vCPUs 16 GiB RAM Network: 4,750 Mbps

Include previous generation classes

You can accept the provided setting, or you can use a different DB instance class for your clone.

- If you choose **Serverless**, you see a **Capacity settings** configuration card.

Capacity settings

This billing estimate is based on published prices. [Learn more](#)

Minimum Aurora capacity unit Info	Maximum Aurora capacity unit Info
1 2GB RAM	64 122GB RAM

[► Additional scaling configuration](#)

You can accept the provided settings, or you can change them for your use case.

- c. For **Additional configuration**, choose settings as you usually do for your Aurora DB clusters.

Additional settings include your choice for the database name and whether you want to use many optional features. These features include backup, Enhanced Monitoring, exporting logs to Amazon CloudWatch, deletion protection, and so on.

Some of the choices displayed depend on the type of clone that you are creating. For example, Aurora Serverless doesn't support Amazon RDS Performance Insights, so that option isn't shown in this case.

Encryption is a standard option available in **Additional configuration**. Aurora Serverless DB clusters are always encrypted. You can create an Aurora Serverless clone only from an Aurora Serverless DB cluster or an encrypted provisioned Aurora DB cluster. However, you can choose a different key for the Aurora Serverless clone than that used for the encrypted provisioned cluster.

Encryption

Enable encryption
Choose to encrypt the given instance. Master key IDs and aliases appear in the list after they have been created using the AWS Key Management Service console. [Info](#)

Master key [Info](#)

lab-tester-key

Account

KMS key ID

When you create an Aurora Serverless clone from an Aurora Serverless DB cluster, you can choose a different key for the clone.

- d. Finish entering all settings for your Aurora DB cluster clone. To learn more about Aurora DB cluster and instance settings, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#).
5. Choose **Create clone** to launch the Aurora clone of your chosen Aurora DB cluster.

When the clone is created, it's listed with your other Aurora DB clusters in the console **Databases** section and displays its current state. Your clone is ready to use when its state is **Available**.

AWS CLI

Using the AWS CLI for cloning your Aurora DB cluster involves a couple of steps.

The `restore-db-cluster-to-point-in-time` AWS CLI command that you use results in an empty Aurora DB cluster with 0 Aurora DB instances. That is, the command restores only the Aurora DB cluster, not the DB instances for that cluster. You do that separately after the clone is available. The two steps in the process are as follows:

1. Create the clone by using the `restore-db-cluster-to-point-in-time` CLI command. The parameters that you use with this command control the capacity type and other details of the empty Aurora DB cluster (clone) being created.
2. Create the Aurora DB instance for the clone by using the `create-db-instance` CLI command to recreate the Aurora DB instance in the restored Aurora DB cluster.

The commands following assume that the AWS CLI is set up with your AWS Region as the default. This approach saves you from passing the `--region` name in each of the commands. For more information, see [Configuring the AWS CLI](#). You can also specify the `--region` in each of the CLI commands that follow.

Topics

- [Creating the clone \(p. 410\)](#)
- [Checking the status and getting clone details \(p. 413\)](#)
- [Creating the Aurora DB instance for your clone \(p. 413\)](#)
- [Parameters to use for cloning \(p. 414\)](#)

Creating the clone

The specific parameters that you pass to the `restore-db-cluster-to-point-in-time` CLI command vary. What you pass depends on the engine-mode type of the source DB cluster—Serverless or Provisioned—and the type of clone that you want to create.

Use the following procedure to create an Aurora Serverless clone from an Aurora Serverless DB cluster, or to create a provisioned Aurora clone from a provisioned Aurora DB cluster.

To create a clone of the same engine mode as the source Aurora DB cluster

- Use the `restore-db-cluster-to-point-in-time` CLI command and specify values for the following parameters:
 - `--db-cluster-identifier` – Choose a meaningful name for your clone. You name the clone when you use the `restore-db-cluster-to-point-in-time` CLI command. You then pass the name of the clone in the `create-db-instance` CLI command.
 - `--restore-type` – Use `copy-on-write` to create a clone of the source DB cluster. Without this parameter, the `restore-db-cluster-to-point-in-time` restores the Aurora DB cluster rather than creating a clone.
 - `--source-db-cluster-identifier` – Use the name of the source Aurora DB cluster that you want to clone.
 - `--use-latest-restorable-time` – This value points to the latest restorable volume data for the clone.

The following example creates a clone named `my-clone` from a cluster named `my-source-cluster`.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
--source-db-cluster-identifier my-source-cluster \
--db-cluster-identifier my-clone \
--restore-type copy-on-write \
--use-latest-restorable-time
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
--source-db-cluster-identifier my-source-cluster ^
--db-cluster-identifier my-clone ^
--restore-type copy-on-write ^
--use-latest-restorable-time
```

The command returns the JSON object containing details of the clone. Check to make sure that your cloned DB cluster is available before trying to create the DB instance for your clone. For more information, see [Checking the status and getting clone details \(p. 413\)](#).

To create a clone with a different engine mode than the source Aurora DB cluster

- Use the `restore-db-cluster-to-point-in-time` CLI command and specify values for the following parameters:
 - `--db-cluster-identifier` – Choose a meaningful name for your clone. You name the clone when you use the `restore-db-cluster-to-point-in-time` CLI command. You then pass the name of the clone in the `create-db-instance` CLI command.
 - `--engine-mode` – Use this parameter only to create clones that are of a different type than the source Aurora DB cluster. Choose the value to pass with `--engine-mode` as follows:
 - Use `provisioned` to create a provisioned Aurora DB cluster clone from an Aurora Serverless DB cluster.
 - Use `serverless` to create an Aurora Serverless DB cluster clone from a provisioned Aurora DB cluster. When you specify `serverless` engine mode, you can also choose `--scaling-configuration`.
 - `--restore-type` – Use `copy-on-write` to create a clone of the source DB cluster. Without this parameter, the `restore-db-cluster-to-point-in-time` restores the Aurora DB cluster rather than creating a clone.

- **--scaling-configuration** – (Optional) Use only with **--engine-mode serverless** to configure the minimum and maximum capacity for the clone. If you don't use this parameter, Aurora creates the clone using a minimum capacity of 1. It uses a maximum capacity that matches the capacity of the source provisioned Aurora DB cluster.
- **--source-db-cluster-identifier** – Use the name of the source Aurora DB cluster that you want to clone.
- **--use-latest-restorable-time** – This value points to the latest restorable volume data for the clone.

The following example creates an Aurora Serverless clone (`my-clone`) from a provisioned Aurora DB cluster named `my-source-cluster`. The provisioned Aurora DB cluster is encrypted.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
  --source-db-cluster-identifier my-source-cluster \
  --db-cluster-identifier my-clone \
  --engine-mode serverless \
  --scaling-configuration MinCapacity=8, MaxCapacity=64 \
  --restore-type copy-on-write \
  --use-latest-restorable-time
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
  --source-db-cluster-identifier my-source-cluster ^
  --db-cluster-identifier my-clone ^
  --engine-mode serverless ^
  --scaling-configuration MinCapacity=8, MaxCapacity=64 ^
  --restore-type copy-on-write ^
  --use-latest-restorable-time
```

These commands return the JSON object containing details of the clone that you need to create the DB instance. You can't do that until the status of the clone (the empty Aurora DB cluster) has the status **Available**.

Note

The `restore-db-cluster-to-point-in-time` AWS CLI command only restores the DB cluster, not the DB instances for that DB cluster. You must invoke the `create-db-instance` command to create DB instances for the restored DB cluster, specifying the identifier of the restored DB cluster in `--db-cluster-identifier`. You can create DB instances only after the `restore-db-cluster-to-point-in-time` command has completed and the DB cluster is available.

For example, suppose you have a cluster named `tpch100g` that you want to clone. The following Linux example creates a cloned cluster named `tpch100g-clone` and a primary instance named `tpch100g-clone-instance` for the new cluster. You don't need to supply some parameters, such as `--master-username` `reinvent` and `--master-user-password`. Aurora automatically determines those from the original cluster. You do need to specify the DB engine to use. Thus, the example tests the new cluster to determine the right value to use for the `--engine` parameter.

```
$ aws rds restore-db-cluster-to-point-in-time \
  --source-db-cluster-identifier tpch100g \
  --db-cluster-identifier tpch100g-clone \
  --restore-type copy-on-write \
  --use-latest-restorable-time

$ aws rds describe-db-clusters \
  --db-cluster-identifier tpch100g-clone \
```

```
--query '*[].[Engine]' \
--output text
aurora

$ aws rds create-db-instance \
--db-instance-identifier tpch100g-clone-instance \
--db-cluster-identifier tpch100g-clone \
--db-instance-class db.r5.4xlarge \
--engine aurora
```

Checking the status and getting clone details

You can use the following command to check the status of your newly created empty DB cluster.

```
$ aws rds describe-db-clusters --db-cluster-identifier my-clone --query '*[].[Status]' --
output text
```

Or you can obtain the status and the other values that you need to [create the DB instance for your clone \(p. 413\)](#) by using the following AWS CLI query.

For Linux, macOS, or Unix:

```
aws rds describe-db-clusters --db-cluster-identifier my-clone \
--query '*[[].
{Status:Status,Engine:Engine,EngineVersion:EngineVersion,EngineMode:EngineMode}'
```

For Windows:

```
aws rds describe-db-clusters --db-cluster-identifier my-clone ^
--query "*[[].
{Status:Status,Engine:Engine,EngineVersion:EngineVersion,EngineMode:EngineMode}"
```

This query returns output similar to the following.

```
[

{
    "Status": "available",
    "Engine": "aurora-mysql",
    "EngineVersion": "5.7.mysql_aurora.2.09.1",
    "EngineMode": "provisioned"
}
```

Creating the Aurora DB instance for your clone

Use the [create-db-instance](#) CLI command to create the DB instance for your clone.

The `--db-instance-class` parameter is used for provisioned Aurora DB clusters only.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier my-new-db \
--db-cluster-identifier my-clone \
--db-instance-class db.r5.4xlarge \
--engine aurora-mysql
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier my-new-db ^
--db-cluster-identifier my-clone ^
--db-instance-class db.r5.4xlarge ^
--engine aurora-mysql
```

For an Aurora Serverless clone created from an Aurora Serverless DB cluster, you specify only a few parameters. The DB instance inherits the --engine-mode, --master-username, and --master-user-password properties from the source DB cluster. You can change the --scaling-configuration.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier my-new-db \
--db-cluster-identifier my-clone \
--engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier my-new-db ^
--db-cluster-identifier my-clone ^
--engine aurora-postgresql
```

Parameters to use for cloning

The following table summarizes the various parameters used with `restore-db-cluster-to-point-in-time` to clone Aurora DB clusters.

Parameter	Description
--source-db-cluster-identifier	Use the name of the source Aurora DB cluster that you want to clone.
--db-cluster-identifier	Choose a meaningful name for your clone. You name your clone with the <code>restore-db-cluster-to-point-in-time</code> command. Then you pass this name to the <code>create-db-instance</code> command.
--engine-mode	Use this parameter to create clones that are of a different type than the source Aurora DB cluster. Choose the value to pass with --engine-mode as follows: <ul style="list-style-type: none"> Use <code>provisioned</code> to create a provisioned Aurora DB cluster clone from an Aurora Serverless DB cluster. Use <code>serverless</code> to create an Aurora Serverless DB cluster clone from a provisioned Aurora DB cluster. When you specify <code>serverless</code> engine mode, you can also choose --scaling-configuration
--restore-type	Specify <code>copy-on-write</code> as the --restore-type to create a clone of the source DB cluster rather than restoring the source Aurora DB cluster.
--scaling-configuration	Use this parameter with --engine-mode <code>serverless</code> to configure the minimum and maximum capacity for the clone. If you don't use this parameter, Aurora creates the Aurora Serverless clone using a minimum capacity of 1 and a maximum capacity of 16.

Parameter	Description
--use-latest-restorable-time	This value points to the latest restorable volume data for the clone.

Cross-account cloning with AWS RAM and Amazon Aurora

By using AWS Resource Access Manager (AWS RAM) with Amazon Aurora, you can share Aurora DB clusters and clones that belong to your AWS account with another AWS account or organization. Such *cross-account cloning* is much faster than creating and restoring a database snapshot. You can create a clone of one of your Aurora DB clusters and share the clone. Or you can share your Aurora DB cluster with another AWS account and let the account holder create the clone. The approach that you choose depends on your use case.

For example, you might need to regularly share a clone of your financial database with your organization's internal auditing team. In this case, your auditing team has its own AWS account for the applications that it uses. You can give the auditing team's AWS account the permission to access your Aurora DB cluster and clone it as needed.

On the other hand, if an outside vendor audits your financial data you might prefer to create the clone yourself. You then give the outside vendor access to the clone only.

You can also use cross-account cloning to support many of the same use cases for cloning within the same AWS account, such as development and testing. For example, your organization might use different AWS accounts for production, development, testing, and so on. For more information, see [Overview of Aurora cloning \(p. 402\)](#).

Thus, you might want to share a clone with another AWS account or allow another AWS account to create clones of your Aurora DB clusters. In either case, start by using AWS RAM to create a share object. For complete information about sharing AWS resources between AWS accounts, see the [AWS RAM User Guide](#).

Creating a cross-account clone requires actions from the AWS account that owns the original cluster, and the AWS account that creates the clone. First, the original cluster owner modifies the cluster to allow one or more other accounts to clone it. If any of the accounts is in a different AWS organization, AWS generates a sharing invitation. The other account must accept the invitation before proceeding. Then each authorized account can clone the cluster. Throughout this process, the cluster is identified by its unique Amazon Resource Name (ARN).

As with cloning within the same AWS account, additional storage space is used only if changes are made to the data by the source or the clone. Charges for storage are then applied at that time. If the source cluster is deleted, storage costs are distributed equally among remaining cloned clusters.

Topics

- [Limitations of cross-account cloning \(p. 415\)](#)
- [Allowing other AWS accounts to clone your cluster \(p. 416\)](#)
- [Cloning a cluster that is owned by another AWS account \(p. 418\)](#)

Limitations of cross-account cloning

Aurora cross-account cloning has the following limitations:

- You can't clone an Aurora Serverless cluster across AWS accounts.

- You can't view or accept invitations to shared resources with the AWS Management Console. Use the AWS CLI, the Amazon RDS API, or the AWS RAM console to view and accept invitations to shared resources.
- You can't create new clones from a clone that's been shared with your AWS account.
- You can't share resources (clones or Aurora DB clusters) that have been shared with your AWS account.
- You can't create more than 15 cross-account clones from any single Aurora DB cluster. Each of these 15 clones must be owned by a different AWS account. That is, you can only create one cross-account clone of a cluster within any AWS account.
- You can't share an Aurora DB cluster with other AWS accounts unless the cluster is in an ACTIVE state.
- You can't rename an Aurora DB cluster that's been shared with other AWS accounts.
- You can't create a cross-account clone of a cluster that is encrypted with the default RDS key.
- You can't create nonencrypted clones in one AWS account from encrypted Aurora DB clusters that have been shared by another AWS account. The cluster owner must grant permission to access the source cluster's AWS KMS key. However, you can use a different key when you create the clone.

Allowing other AWS accounts to clone your cluster

To allow other AWS accounts to clone a cluster that you own, use AWS RAM to set the sharing permission. Doing so also sends an invitation to each of the other accounts that's in a different AWS organization.

For the procedures to share resources owned by you in the AWS RAM console, see [Sharing resources owned by you](#) in the *AWS RAM User Guide*.

Topics

- [Granting permission to other AWS accounts to clone your cluster \(p. 416\)](#)
- [Checking if a cluster that you own is shared with other AWS accounts \(p. 418\)](#)

Granting permission to other AWS accounts to clone your cluster

If the cluster that you're sharing is encrypted, you also share the AWS KMS key for the cluster. You can allow AWS Identity and Access Management (IAM) users or roles in one AWS account to use a KMS key in a different account.

To do this, you first add the external account (root user) to the KMS key's key policy through AWS KMS. You don't add the individual IAM users or roles to the key policy, only the external account that owns them. You can only share a KMS key that you create, not the default RDS service key. For information about access control for KMS keys, see [Authentication and access control for AWS KMS](#).

Console

To grant permission to clone your cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster that you want to share to see its **Details** page, and choose the **Connectivity & security** tab.
4. In the **Share DB cluster with other AWS accounts** section, enter the numeric account ID for the AWS account that you want to allow to clone this cluster. For account IDs in the same organization, you can begin typing in the box and then choose from the menu.

Important

In some cases, you might want an account that is not in the same AWS organization as your account to clone a cluster. In these cases, for security reasons the console doesn't report who owns that account ID or whether the account exists.

Be careful entering account numbers that are not in the same AWS organization as your AWS account. Immediately verify that you shared with the intended account.

5. On the confirmation page, verify that the account ID that you specified is correct. Enter `share` in the confirmation box to confirm.

On the **Details** page, an entry appears that shows the specified AWS account ID under **Accounts that this DB cluster is shared with**. The **Status** column initially shows a status of **Pending**.

6. Contact the owner of the other AWS account, or sign in to that account if you own both of them. Instruct the owner of the other account to accept the sharing invitation and clone the DB cluster, as described following.

AWS CLI

To grant permission to clone your cluster

1. Gather the information for the required parameters. You need the ARN for your cluster and the numeric ID for the other AWS account.
2. Run the AWS RAM CLI command `create-resource-share`.

For Linux, macOS, or Unix:

```
aws ram create-resource-share --name descriptive_name \  
  --region region \  
  --resource-arns cluster_arn \  
  --principals other_account_ids
```

For Windows:

```
aws ram create-resource-share --name descriptive_name ^  
  --region region ^  
  --resource-arns cluster_arn ^  
  --principals other_account_ids
```

To include multiple account IDs for the `--principals` parameter, separate IDs from each other with spaces. To specify whether the permitted account IDs can be outside your AWS organization, include the `--allow-external-principals` or `--no-allow-external-principals` parameter for `create-resource-share`.

AWS RAM API

To grant permission to clone your cluster

1. Gather the information for the required parameters. You need the ARN for your cluster and the numeric ID for the other AWS account.
2. Call the AWS RAM API operation `CreateResourceShare`, and specify the following values:
 - Specify the account ID for one or more AWS accounts as the `principals` parameter.
 - Specify the ARN for one or more Aurora DB clusters as the `resourceArns` parameter.
 - Specify whether the permitted account IDs can be outside your AWS organization by including a Boolean value for the `allowExternalPrincipals` parameter.

Recreating a cluster that uses the default RDS key

If the encrypted cluster that you plan to share uses the default RDS key, make sure to recreate the cluster. To do this, create a manual snapshot of your DB cluster, use an AWS KMS key, and then restore the cluster to a new cluster. Then share the new cluster. To perform this process, take the following steps.

To recreate an encrypted cluster that uses the default RDS key

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Snapshots** from the navigation pane.
3. Choose your snapshot.
4. For **Actions**, choose **Copy Snapshot**, and then choose **Enable encryption**.
5. For **AWS KMS key**, choose the new encryption key that you want to use.
6. Restore the copied snapshot. To do so, follow the procedure in [Restoring from a DB cluster snapshot \(p. 497\)](#). The new DB instance uses your new encryption key.
7. (Optional) Delete the old DB cluster if you no longer need it. To do so, follow the procedure in [Deleting a DB cluster snapshot \(p. 539\)](#). Before you do, confirm that your new cluster has all necessary data and that your application can access it successfully.

Checking if a cluster that you own is shared with other AWS accounts

You can check if other users have permission to share a cluster. Doing so can help you understand whether the cluster is approaching the limit for the maximum number of cross-account clones.

For the procedures to share resources using the AWS RAM console, see [Sharing resources owned by you in the AWS RAM User Guide](#).

AWS CLI

To find out if a cluster that you own is shared with other AWS accounts

- Call the AWS RAM CLI command `list-principals`, using your account ID as the resource owner and the ARN of your cluster as the resource ARN. You can see all shares with the following command. The results indicate which AWS accounts are allowed to clone the cluster.

```
aws ram list-principals \
    --resource-arns your_cluster_arn \
    --principals your_aws_id
```

AWS RAM API

To find out if a cluster that you own is shared with other AWS accounts

- Call the AWS RAM API operation `ListPrincipals`. Use your account ID as the resource owner and the ARN of your cluster as the resource ARN.

Cloning a cluster that is owned by another AWS account

To clone a cluster that's owned by another AWS account, use AWS RAM to get permission to make the clone. After you have the required permission, use the standard procedure for cloning an Aurora cluster.

You can also check whether a cluster that you own is a clone of a cluster owned by a different AWS account.

For the procedures to work with resources owned by others in the AWS RAM console, see [Accessing resources shared with you](#) in the *AWS RAM User Guide*.

Topics

- [Viewing invitations to clone clusters that are owned by other AWS accounts \(p. 419\)](#)
- [Accepting invitations to share clusters owned by other AWS accounts \(p. 419\)](#)
- [Cloning an Aurora cluster that is owned by another AWS account \(p. 420\)](#)
- [Checking if a DB cluster is a cross-account clone \(p. 423\)](#)

Viewing invitations to clone clusters that are owned by other AWS accounts

To work with invitations to clone clusters owned by AWS accounts in other AWS organizations, use the AWS CLI, the AWS RAM console, or the AWS RAM API. Currently, you can't perform this procedure using the Amazon RDS console.

For the procedures to work with invitations in the AWS RAM console, see [Accessing resources shared with you](#) in the *AWS RAM User Guide*.

AWS CLI

To see invitations to clone clusters that are owned by other AWS accounts

1. Run the AWS RAM CLI command [get-resource-share-invitations](#).

```
aws ram get-resource-share-invitations --region region_name
```

The results from the preceding command show all invitations to clone clusters, including any that you already accepted or rejected.

2. (Optional) Filter the list so you see only the invitations that require action from you. To do so, add the parameter `--query 'resourceShareInvitations[?status==`PENDING`]`.

AWS RAM API

To see invitations to clone clusters that are owned by other AWS accounts

1. Call the AWS RAM API operation [GetResourceShareInvitations](#). This operation returns all such invitations, including any that you already accepted or rejected.
2. (Optional) Find only the invitations that require action from you by checking the `resourceShareAssociations` return field for a `status` value of PENDING.

Accepting invitations to share clusters owned by other AWS accounts

You can accept invitations to share clusters owned by other AWS accounts that are in different AWS organizations. To work with these invitations, use the AWS CLI, the AWS RAM and RDS APIs, or the AWS RAM console. Currently, you can't perform this procedure using the RDS console.

For the procedures to work with invitations in the AWS RAM console, see [Accessing resources shared with you](#) in the *AWS RAM User Guide*.

Console

To accept an invitation to share a cluster from another AWS account

1. Find the invitation ARN by running the AWS RAM CLI command [get-resource-share-invitations](#), as shown preceding.

2. Accept the invitation by calling the AWS RAM CLI command [accept-resource-share-invitation](#), as shown following.

For Linux, macOS, or Unix:

```
aws ram accept-resource-share-invitation \
--resource-share-invitation-arn invitation_arn \
--region region
```

For Windows:

```
aws ram accept-resource-share-invitation ^
--resource-share-invitation-arn invitation_arn ^
--region region
```

AWS RAM and RDS API

To accept invitations to share somebody's cluster

1. Find the invitation ARN by calling the AWS RAM API operation [GetResourceShareInvitations](#), as shown preceding.
2. Pass that ARN as the `resourceShareInvitationArn` parameter to the RDS API operation [AcceptResourceShareInvitation](#).

Cloning an Aurora cluster that is owned by another AWS account

After you accept the invitation from the AWS account that owns the DB cluster, as shown preceding, you can clone the cluster.

Console

To clone an Aurora cluster that is owned by another AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

At the top of the database list, you should see one or more items with a **Role** value of `Shared from account #account_id`. For security reasons, you can only see limited information about the original clusters. The properties that you can see are the ones such as database engine and version that must be the same in your cloned cluster.

3. Choose the cluster that you intend to clone.
4. For **Actions**, choose **Create clone**.
5. Follow the procedure in [Console \(p. 407\)](#) to finish setting up the cloned cluster.
6. As needed, enable encryption for the cloned cluster. If the cluster that you are cloning is encrypted, you must enable encryption for the cloned cluster. The AWS account that shared the cluster with you must also share the KMS key that was used to encrypt the cluster. You can use the same KMS key to encrypt the clone, or your own KMS key. You can't create a cross-account clone for a cluster that is encrypted with the default KMS key.

The account that owns the encryption key must grant permission to use the key to the destination account by using a key policy. This process is similar to how encrypted snapshots are shared, by using a key policy that grants permission to the destination account to use the key.

AWS CLI

To clone an Aurora cluster owned by another AWS account

1. Accept the invitation from the AWS account that owns the DB cluster, as shown preceding.
2. Clone the cluster by specifying the full ARN of the source cluster in the `source-db-cluster-identifier` parameter of the RDS CLI command `restore-db-cluster-to-point-in-time`, as shown following.

If the ARN passed as the `source-db-cluster-identifier` hasn't been shared, the same error is returned as if the specified cluster doesn't exist.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
--source-db-cluster-identifier=arn:aws:rds:arn_details \
--db-cluster-identifier=new_cluster_id \
--restore-type=copy-on-write \
--use-latest-restorable-time
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
--source-db-cluster-identifier=arn:aws:rds:arn_details ^
--db-cluster-identifier=new_cluster_id ^
--restore-type=copy-on-write ^
--use-latest-restorable-time
```

3. If the cluster that you are cloning is encrypted, encrypt your cloned cluster by including a `kms-key-id` parameter. This `kms-key-id` value can be the same one used to encrypt the original DB cluster, or your own KMS key. Your account must have permission to use that encryption key.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
--source-db-cluster-identifier=arn:aws:rds:arn_details \
--db-cluster-identifier=new_cluster_id \
--restore-type=copy-on-write \
--use-latest-restorable-time \
--kms-key-id=arn:aws:kms:arn_details
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
--source-db-cluster-identifier=arn:aws:rds:arn_details ^
--db-cluster-identifier=new_cluster_id ^
--restore-type=copy-on-write ^
--use-latest-restorable-time ^
--kms-key-id=arn:aws:kms:arn_details
```

The account that owns the encryption key must grant permission to use the key to the destination account by using a key policy. This process is similar to how encrypted snapshots are shared, by using a key policy that grants permission to the destination account to use the key. An example of a key policy follows.

```
{  
  "Id": "key-policy-1",  
  "Version": "2012-10-17",  
  "Statement": [
```

```
"Statement": [
    {
        "Sid": "Allow use of the key",
        "Effect": "Allow",
        "Principal": {"AWS": [
            "arn:aws:iam::account_id:user/KeyUser",
            "arn:aws:iam::account_id:root"
        ]},
        "Action": [
            "kms>CreateGrant",
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:ReEncrypt",
            "kms:GenerateDataKey*",
            "kms:DescribeKey"
        ],
        "Resource": "*"
    },
    {
        "Sid": "Allow attachment of persistent resources",
        "Effect": "Allow",
        "Principal": {"AWS": [
            "arn:aws:iam::account_id:user/KeyUser",
            "arn:aws:iam::account_id:root"
        ]},
        "Action": [
            "kms>CreateGrant",
            "kms>ListGrants",
            "kms:RevokeGrant"
        ],
        "Resource": "*",
        "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
    }
]
```

Note

The [restore-db-cluster-to-point-in-time](#) AWS CLI command restores only the DB cluster, not the DB instances for that DB cluster. To create DB instances for the restored DB cluster, invoke the [create-db-instance](#) command. Specify the identifier of the restored DB cluster in `--db-cluster-identifier`.

You can create DB instances only after the [restore-db-cluster-to-point-in-time](#) command has completed and the DB cluster is available.

RDS API

To clone an Aurora cluster owned by another AWS account

1. Accept the invitation from the AWS account that owns the DB cluster, as shown preceding.
2. Clone the cluster by specifying the full ARN of the source cluster in the `SourceDBClusterIdentifier` parameter of the RDS API operation [RestoreDBClusterToPointInTime](#).

If the ARN passed as the `SourceDBClusterIdentifier` hasn't been shared, then the same error is returned as if the specified cluster doesn't exist.

3. If the cluster that you are cloning is encrypted, include a `KmsKeyId` parameter to encrypt your cloned cluster. This `kms-key-id` value can be the same one used to encrypt the original DB cluster, or your own KMS key. Your account must have permission to use that encryption key.

When you clone a volume, the destination account must have permission to use the encryption key used to encrypt the source cluster. Aurora encrypts the new cloned cluster with the encryption key specified in `KmsKeyId`.

The account that owns the encryption key must grant permission to use the key to the destination account by using a key policy. This process is similar to how encrypted snapshots are shared, by using a key policy that grants permission to the destination account to use the key. An example of a key policy follows.

```
{
  "Id": "key-policy-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Allow use of the key",
      "Effect": "Allow",
      "Principal": {"AWS": [
        "arn:aws:iam::account_id:user/KeyUser",
        "arn:aws:iam::account_id:root"
      ]},
      "Action": [
        "kms>CreateGrant",
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
      ],
      "Resource": "*"
    },
    {
      "Sid": "Allow attachment of persistent resources",
      "Effect": "Allow",
      "Principal": {"AWS": [
        "arn:aws:iam::account_id:user/KeyUser",
        "arn:aws:iam::account_id:root"
      ]},
      "Action": [
        "kms>CreateGrant",
        "kms>ListGrants",
        "kms:RevokeGrant"
      ],
      "Resource": "*",
      "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
    }
  ]
}
```

Note

The [RestoreDBClusterToPointInTime](#) RDS API operation restores only the DB cluster, not the DB instances for that DB cluster. To create DB instances for the restored DB cluster, invoke the [CreateDBInstance](#) RDS API operation. Specify the identifier of the restored DB cluster in `DBClusterIdentifier`. You can create DB instances only after the `RestoreDBClusterToPointInTime` operation has completed and the DB cluster is available.

Checking if a DB cluster is a cross-account clone

The `DBClusters` object identifies whether each cluster is a cross-account clone. You can see the clusters that you have permission to clone by using the `include-shared` option when you run the RDS CLI

command `describe-db-clusters`. However, you can't see most of the configuration details for such clusters.

AWS CLI

To check if a DB cluster is a cross-account clone

- Call the RDS CLI command `describe-db-clusters`.

The following example shows how actual or potential cross-account clone DB clusters appear in `describe-db-clusters` output. For existing clusters owned by your AWS account, the `CrossAccountClone` field indicates whether the cluster is a clone of a DB cluster that is owned by another AWS account.

In some cases, an entry might have a different AWS account number than yours in the `DBClusterArn` field. In this case, that entry represents a cluster that is owned by a different AWS account and that you can clone. Such entries have few fields other than `DBClusterArn`. When creating the cloned cluster, specify the same `StorageEncrypted`, `Engine`, and `EngineVersion` values as in the original cluster.

```
$ aws rds describe-db-clusters --include-shared --region us-east-1
{
  "DBClusters": [
    {
      "EarliestRestorableTime": "2019-05-01T21:17:54.106Z",
      "Engine": "aurora",
      "EngineVersion": "5.6.10a",
      "CrossAccountClone": false,
      ...
    },
    {
      "EarliestRestorableTime": "2019-04-09T16:01:07.398Z",
      "Engine": "aurora",
      "EngineVersion": "5.6.10a",
      "CrossAccountClone": true,
      ...
    },
    {
      "StorageEncrypted": false,
      "DBClusterArn": "arn:aws:rds:us-east-1:12345678:cluster:cluster-abcdefg",
      "Engine": "aurora",
      "EngineVersion": "5.6.10a",
    }
  ]
}
```

RDS API

To check if a DB cluster is a cross-account clone

- Call the RDS API operation `DescribeDBClusters`.

For existing clusters owned by your AWS account, the `CrossAccountClone` field indicates whether the cluster is a clone of a DB cluster owned by another AWS account. Entries with a different AWS account number in the `DBClusterArn` field represent clusters that you can clone and that are owned by other AWS accounts. These entries have few fields other than `DBClusterArn`. When creating the cloned cluster, specify the same `StorageEncrypted`, `Engine`, and `EngineVersion` values as in the original cluster.

The following example shows a return value that demonstrates both actual and potential cloned clusters.

```
{  
    "DBClusters": [  
        {  
            "EarliestRestorableTime": "2019-05-01T21:17:54.106Z",  
            "Engine": "aurora",  
            "EngineVersion": "5.6.10a",  
            "CrossAccountClone": false,  
            ...  
        },  
        {  
            "EarliestRestorableTime": "2019-04-09T16:01:07.398Z",  
            "Engine": "aurora",  
            "EngineVersion": "5.6.10a",  
            "CrossAccountClone": true,  
            ...  
        },  
        {  
            "StorageEncrypted": false,  
            "DBClusterArn": "arn:aws:rds:us-east-1:12345678:cluster:cluster-abcdefgh",  
            "Engine": "aurora",  
            "EngineVersion": "5.6.10a"  
        }  
    ]  
}
```

Integrating Aurora with other AWS services

Integrate Amazon Aurora with other AWS services so that you can extend your Aurora DB cluster to use additional capabilities in the AWS Cloud.

Topics

- [Integrating AWS services with Amazon Aurora MySQL \(p. 426\)](#)
- [Integrating AWS services with Amazon Aurora PostgreSQL \(p. 426\)](#)
- [Using Amazon Aurora Auto Scaling with Aurora replicas \(p. 427\)](#)
- [Using machine learning \(ML\) capabilities with Amazon Aurora \(p. 442\)](#)

Integrating AWS services with Amazon Aurora MySQL

Amazon Aurora MySQL integrates with other AWS services so that you can extend your Aurora MySQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora MySQL DB cluster can use AWS services to do the following:

- Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. Or, asynchronously invoke an AWS Lambda function using the `mysql.lambda_async` procedure.
- Load data from text or XML files stored in an Amazon S3 bucket into your DB cluster using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` command.
- Save data to text files stored in an Amazon S3 bucket from your DB cluster using the `SELECT INTO OUTFILE S3` command.
- Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see [Using Amazon Aurora Auto Scaling with Aurora replicas \(p. 427\)](#).

For more information about integrating Aurora MySQL with other AWS services, see [Integrating Amazon Aurora MySQL with other AWS services \(p. 984\)](#).

Integrating AWS services with Amazon Aurora PostgreSQL

Amazon Aurora PostgreSQL integrates with other AWS services so that you can extend your Aurora PostgreSQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora PostgreSQL DB cluster can use AWS services to do the following:

- Quickly collect, view, and assess performance on your relational database workloads with Performance Insights.
- Automatically add or remove Aurora Replicas with Aurora Auto Scaling. For more information, see [Using Amazon Aurora Auto Scaling with Aurora replicas \(p. 427\)](#).

For more information about integrating Aurora PostgreSQL with other AWS services, see [Integrating Amazon Aurora PostgreSQL with other AWS services \(p. 1437\)](#).

Using Amazon Aurora Auto Scaling with Aurora replicas

To meet your connectivity and workload requirements, Aurora Auto Scaling dynamically adjusts the number of Aurora Replicas provisioned for an Aurora DB cluster using single-master replication. Aurora Auto Scaling is available for both Aurora MySQL and Aurora PostgreSQL. Aurora Auto Scaling enables your Aurora DB cluster to handle sudden increases in connectivity or workload. When the connectivity or workload decreases, Aurora Auto Scaling removes unnecessary Aurora Replicas so that you don't pay for unused provisioned DB instances.

You define and apply a scaling policy to an Aurora DB cluster. The *scaling policy* defines the minimum and maximum number of Aurora Replicas that Aurora Auto Scaling can manage. Based on the policy, Aurora Auto Scaling adjusts the number of Aurora Replicas up or down in response to actual workloads, determined by using Amazon CloudWatch metrics and target values.

You can use the AWS Management Console to apply a scaling policy based on a predefined metric. Alternatively, you can use either the AWS CLI or Aurora Auto Scaling API to apply a scaling policy based on a predefined or custom metric.

Topics

- [Before you begin \(p. 427\)](#)
- [Aurora Auto Scaling policies \(p. 428\)](#)
- [Adding a scaling policy \(p. 429\)](#)
- [Editing a scaling policy \(p. 438\)](#)
- [Deleting a scaling policy \(p. 440\)](#)
- [DB instance IDs and tagging \(p. 441\)](#)

Before you begin

Before you can use Aurora Auto Scaling with an Aurora DB cluster, you must first create an Aurora DB cluster with a primary instance and at least one Aurora Replica. Although Aurora Auto Scaling manages Aurora Replicas, the Aurora DB cluster must start with at least one Aurora Replica. For more information about creating an Aurora DB cluster, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

Aurora Auto Scaling only scales a DB cluster if all Aurora Replicas in a DB cluster are in the available state. If any of the Aurora Replicas are in a state other than available, Aurora Auto Scaling waits until the whole DB cluster becomes available for scaling.

When Aurora Auto Scaling adds a new Aurora Replica, the new Aurora Replica is the same DB instance class as the one used by the primary instance. For more information about DB instance classes, see [Aurora DB instance classes \(p. 54\)](#). Also, the promotion tier for new Aurora Replicas is set to the last priority, which is 15 by default. This means that during a failover, a replica with a better priority, such as one created manually, would be promoted first. For more information, see [Fault tolerance for an Aurora DB cluster \(p. 69\)](#).

Aurora Auto Scaling only removes Aurora Replicas that it created.

To benefit from Aurora Auto Scaling, your applications must support connections to new Aurora Replicas. To do so, we recommend using the Aurora reader endpoint. For Aurora MySQL you can use a driver such as the MariaDB Connector/J utility. For more information, see [Connecting to an Amazon Aurora DB cluster \(p. 281\)](#).

Note

Aurora global databases currently don't support Aurora Auto Scaling for secondary DB clusters.

Aurora Auto Scaling policies

Aurora Auto Scaling uses a scaling policy to adjust the number of Aurora Replicas in an Aurora DB cluster. Aurora Auto Scaling has the following components:

- A service-linked role
- A target metric
- Minimum and maximum capacity
- A cooldown period

Service linked role

Aurora Auto Scaling uses the `AWSServiceRoleForApplicationAutoScaling_RDSCluster` service-linked role. For more information, see [Service-linked roles for Application Auto Scaling](#) in the *Application Auto Scaling User Guide*.

Target metric

In this type of policy, a predefined or custom metric and a target value for the metric is specified in a target-tracking scaling policy configuration. Aurora Auto Scaling creates and manages CloudWatch alarms that trigger the scaling policy and calculates the scaling adjustment based on the metric and target value. The scaling policy adds or removes Aurora Replicas as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target-tracking scaling policy also adjusts to fluctuations in the metric due to a changing workload. Such a policy also minimizes rapid fluctuations in the number of available Aurora Replicas for your DB cluster.

For example, take a scaling policy that uses the predefined average CPU utilization metric. Such a policy can keep CPU utilization at, or close to, a specified percentage of utilization, such as 40 percent.

Note

For each Aurora DB cluster, you can create only one Auto Scaling policy for each target metric.

Minimum and maximum capacity

You can specify the maximum number of Aurora Replicas to be managed by Application Auto Scaling. This value must be set to 0–15, and must be equal to or greater than the value specified for the minimum number of Aurora Replicas.

You can also specify the minimum number of Aurora Replicas to be managed by Application Auto Scaling. This value must be set to 0–15, and must be equal to or less than the value specified for the maximum number of Aurora Replicas.

Note

The minimum and maximum capacity are set for an Aurora DB cluster. The specified values apply to all of the policies associated with that Aurora DB cluster.

Cooldown period

You can tune the responsiveness of a target-tracking scaling policy by adding cooldown periods that affect scaling your Aurora DB cluster in and out. A cooldown period blocks subsequent scale-in or scale-out requests until the period expires. These blocks slow the deletions of Aurora Replicas in your Aurora DB cluster for scale-in requests, and the creation of Aurora Replicas for scale-out requests.

You can specify the following cooldown periods:

- A scale-in activity reduces the number of Aurora Replicas in your Aurora DB cluster. A scale-in cooldown period specifies the amount of time, in seconds, after a scale-in activity completes before another scale-in activity can start.

- A scale-out activity increases the number of Aurora Replicas in your Aurora DB cluster. A scale-out cooldown period specifies the amount of time, in seconds, after a scale-out activity completes before another scale-out activity can start.

When a scale-in or a scale-out cooldown period is not specified, the default for each is 300 seconds.

Enable or disable scale-in activities

You can enable or disable scale-in activities for a policy. Enabling scale-in activities allows the scaling policy to delete Aurora Replicas. When scale-in activities are enabled, the scale-in cooldown period in the scaling policy applies to scale-in activities. Disabling scale-in activities prevents the scaling policy from deleting Aurora Replicas.

Note

Scale-out activities are always enabled so that the scaling policy can create Aurora Replicas as needed.

Adding a scaling policy

You can add a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Note

For an example that adds a scaling policy using AWS CloudFormation, see [Declaring a scaling policy for an Aurora DB cluster](#) in the *AWS CloudFormation User Guide*.

Topics

- [Adding a scaling policy using the AWS Management Console \(p. 429\)](#)
- [Adding a scaling policy using the AWS CLI or the Application Auto Scaling API \(p. 432\)](#)

Adding a scaling policy using the AWS Management Console

You can add a scaling policy to an Aurora DB cluster by using the AWS Management Console.

To add an auto scaling policy to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora DB cluster that you want to add a policy for.
4. Choose the **Logs & events** tab.
5. In the **Auto scaling policies** section, choose **Add**.

The **Add Auto Scaling policy** dialog box appears.

6. For **Policy Name**, type the policy name.
7. For the target metric, choose one of the following:
 - **Average CPU utilization of Aurora Replicas** to create a policy based on the average CPU utilization.
 - **Average connections of Aurora Replicas** to create a policy based on the average number of connections to Aurora Replicas.
8. For the target value, type one of the following:

- If you chose **Average CPU utilization of Aurora Replicas** in the previous step, type the percentage of CPU utilization that you want to maintain on Aurora Replicas.
- If you chose **Average connections of Aurora Replicas** in the previous step, type the number of connections that you want to maintain.

Aurora Replicas are added or removed to keep the metric close to the specified value.

9. (Optional) Open **Additional Configuration** to create a scale-in or scale-out cooldown period.
10. For **Minimum capacity**, type the minimum number of Aurora Replicas that the Aurora Auto Scaling policy is required to maintain.
11. For **Maximum capacity**, type the maximum number of Aurora Replicas the Aurora Auto Scaling policy is required to maintain.
12. Choose **Add policy**.

The following dialog box creates an Auto Scaling policy based an average CPU utilization of 40 percent. The policy specifies a minimum of 5 Aurora Replicas and a maximum of 15 Aurora Replicas.

Add Auto Scaling policy

Add policy

Adding a scaling policy using the AWS CLI or the Application Auto Scaling API

You can apply a scaling policy based on either a predefined or custom metric. To do so, you can use the AWS CLI or the Application Auto Scaling API. The first step is to register your Aurora DB cluster with Application Auto Scaling.

Registering an Aurora DB cluster

Before you can use Aurora Auto Scaling with an Aurora DB cluster, you register your Aurora DB cluster with Application Auto Scaling. You do so to define the scaling dimension and limits to be applied to that cluster. Application Auto Scaling dynamically scales the Aurora DB cluster along the

`rds:cluster:ReadReplicaCount` scalable dimension, which represents the number of Aurora Replicas.

To register your Aurora DB cluster, you can use either the AWS CLI or the Application Auto Scaling API.

AWS CLI

To register your Aurora DB cluster, use the `register-scalable-target` AWS CLI command with the following parameters:

- `--service-namespace` – Set this value to `rds`.
- `--resource-id` – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:mscalablecluster`.
- `--scalable-dimension` – Set this value to `rds:cluster:ReadReplicaCount`.
- `--min-capacity` – The minimum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of DB instances in your cluster, see [Minimum and maximum capacity \(p. 428\)](#).
- `--max-capacity` – The maximum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of DB instances in your cluster, see [Minimum and maximum capacity \(p. 428\)](#).

Example

In the following example, you register an Aurora DB cluster named `mscalablecluster`. The registration indicates that the DB cluster should be dynamically scaled to have from one to eight Aurora Replicas.

For Linux, macOS, or Unix:

```
aws application-autoscaling register-scalable-target \
--service-namespace rds \
--resource-id cluster:mscalablecluster \
--scalable-dimension rds:cluster:ReadReplicaCount \
--min-capacity 1 \
--max-capacity 8
```

For Windows:

```
aws application-autoscaling register-scalable-target ^
--service-namespace rds ^
--resource-id cluster:mscalablecluster ^
--scalable-dimension rds:cluster:ReadReplicaCount ^
--min-capacity 1 ^
--max-capacity 8 ^
```

RDS API

To register your Aurora DB cluster with Application Auto Scaling, use the `RegisterScalableTarget` Application Auto Scaling API operation with the following parameters:

- `ServiceNamespace` – Set this value to `rds`.
- `ResourceID` – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:mscalablecluster`.

- **ScalableDimension** – Set this value to `rds:cluster:ReadReplicaCount`.
- **MinCapacity** – The minimum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between `MinCapacity`, `MaxCapacity`, and the number of DB instances in your cluster, see [Minimum and maximum capacity \(p. 428\)](#).
- **MaxCapacity** – The maximum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between `MinCapacity`, `MaxCapacity`, and the number of DB instances in your cluster, see [Minimum and maximum capacity \(p. 428\)](#).

Example

In the following example, you register an Aurora DB cluster named `mscalablecluster` with the Application Auto Scaling API. This registration indicates that the DB cluster should be dynamically scaled to have from one to eight Aurora Replicas.

```

Authorization: AUTHPARAMS

{
    "ServiceNamespace": "rds",
    "ResourceId": "cluster:mscalablecluster",
    "ScalableDimension": "rds:cluster:ReadReplicaCount",
    "MinCapacity": 1,
    "MaxCapacity": 8
}
```

Defining a scaling policy for an Aurora DB cluster

A target-tracking scaling policy configuration is represented by a JSON block that the metrics and target values are defined in. You can save a scaling policy configuration as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see [TargetTrackingScalingPolicyConfiguration](#) in the *Application Auto Scaling API Reference*.

The following options are available for defining a target-tracking scaling policy configuration.

Topics

- [Using a predefined metric \(p. 434\)](#)
- [Using a custom metric \(p. 435\)](#)
- [Using cooldown periods \(p. 435\)](#)
- [Disabling scale-in activity \(p. 436\)](#)

Using a predefined metric

By using predefined metrics, you can quickly define a target-tracking scaling policy for an Aurora DB cluster that works well with both target tracking and dynamic scaling in Aurora Auto Scaling.

Currently, Aurora supports the following predefined metrics in Aurora Auto Scaling:

- **RDSReaderAverageCPUUtilization** – The average value of the `CPUUtilization` metric in CloudWatch across all Aurora Replicas in the Aurora DB cluster.

- **RDSReaderAverageDatabaseConnections** – The average value of the DatabaseConnections metric in CloudWatch across all Aurora Replicas in the Aurora DB cluster.

For more information about the CPUUtilization and DatabaseConnections metrics, see [Amazon CloudWatch metrics for Amazon Aurora \(p. 633\)](#).

To use a predefined metric in your scaling policy, you create a target tracking configuration for your scaling policy. This configuration must include a PredefinedMetricSpecification for the predefined metric and a TargetValue for the target value of that metric.

Example

The following example describes a typical policy configuration for target-tracking scaling for an Aurora DB cluster. In this configuration, the RDSReaderAverageCPUUtilization predefined metric is used to adjust the Aurora DB cluster based on an average CPU utilization of 40 percent across all Aurora Replicas.

```
{
    "TargetValue": 40.0,
    "PredefinedMetricSpecification":
    {
        "PredefinedMetricType": "RDSReaderAverageCPUUtilization"
    }
}
```

Using a custom metric

By using custom metrics, you can define a target-tracking scaling policy that meets your custom requirements. You can define a custom metric based on any Aurora metric that changes in proportion to scaling.

Not all Aurora metrics work for target tracking. The metric must be a valid utilization metric and describe how busy an instance is. The value of the metric must increase or decrease in proportion to the number of Aurora Replicas in the Aurora DB cluster. This proportional increase or decrease is necessary to use the metric data to proportionally scale out or in the number of Aurora Replicas.

Example

The following example describes a target-tracking configuration for a scaling policy. In this configuration, a custom metric adjusts an Aurora DB cluster based on an average CPU utilization of 50 percent across all Aurora Replicas in an Aurora DB cluster named `my-db-cluster`.

```
{
    "TargetValue": 50,
    "CustomizedMetricSpecification":
    {
        "MetricName": "CPUUtilization",
        "Namespace": "AWS/RDS",
        "Dimensions": [
            {"Name": "DBClusterIdentifier", "Value": "my-db-cluster"},
            {"Name": "Role", "Value": "READER"}
        ],
        "Statistic": "Average",
        "Unit": "Percent"
    }
}
```

Using cooldown periods

You can specify a value, in seconds, for `ScaleOutCooldown` to add a cooldown period for scaling out your Aurora DB cluster. Similarly, you can add a value, in seconds, for `ScaleInCooldown` to add a

cooldown period for scaling in your Aurora DB cluster. For more information about `ScaleInCooldown` and `ScaleOutCooldown`, see [TargetTrackingScalingPolicyConfiguration](#) in the *Application Auto Scaling API Reference*.

Example

The following example describes a target-tracking configuration for a scaling policy. In this configuration, the `RDSReaderAverageCPUUtilization` predefined metric is used to adjust an Aurora DB cluster based on an average CPU utilization of 40 percent across all Aurora Replicas in that Aurora DB cluster. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```
{  
    "TargetValue": 40.0,  
    "PredefinedMetricSpecification":  
    {  
        "PredefinedMetricType": "RDSReaderAverageCPUUtilization"  
    },  
    "ScaleInCooldown": 600,  
    "ScaleOutCooldown": 300  
}
```

Disabling scale-in activity

You can prevent the target-tracking scaling policy configuration from scaling in your Aurora DB cluster by disabling scale-in activity. Disabling scale-in activity prevents the scaling policy from deleting Aurora Replicas, while still allowing the scaling policy to create them as needed.

You can specify a Boolean value for `DisableScaleIn` to enable or disable scale in activity for your Aurora DB cluster. For more information about `DisableScaleIn`, see [TargetTrackingScalingPolicyConfiguration](#) in the *Application Auto Scaling API Reference*.

Example

The following example describes a target-tracking configuration for a scaling policy. In this configuration, the `RDSReaderAverageCPUUtilization` predefined metric adjusts an Aurora DB cluster based on an average CPU utilization of 40 percent across all Aurora Replicas in that Aurora DB cluster. The configuration disables scale-in activity for the scaling policy.

```
{  
    "TargetValue": 40.0,  
    "PredefinedMetricSpecification":  
    {  
        "PredefinedMetricType": "RDSReaderAverageCPUUtilization"  
    },  
    "DisableScaleIn": true  
}
```

Applying a scaling policy to an Aurora DB cluster

After registering your Aurora DB cluster with Application Auto Scaling and defining a scaling policy, you apply the scaling policy to the registered Aurora DB cluster. To apply a scaling policy to an Aurora DB cluster, you can use the AWS CLI or the Application Auto Scaling API.

AWS CLI

To apply a scaling policy to your Aurora DB cluster, use the `put-scaling-policy` AWS CLI command with the following parameters:

- `--policy-name` – The name of the scaling policy.
- `--policy-type` – Set this value to `TargetTrackingScaling`.

- **--resource-id** – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`.
- **--service-namespace** – Set this value to `rds`.
- **--scalable-dimension** – Set this value to `rds:cluster:ReadReplicaCount`.
- **--target-tracking-scaling-policy-configuration** – The target-tracking scaling policy configuration to use for the Aurora DB cluster.

Example

In the following example, you apply a target-tracking scaling policy named `myscalablepolicy` to an Aurora DB cluster named `myscalablecluster` with Application Auto Scaling. To do so, you use a policy configuration saved in a file named `config.json`.

For Linux, macOS, or Unix:

```
aws application-autoscaling put-scaling-policy \
  --policy-name myscalablepolicy \
  --policy-type TargetTrackingScaling \
  --resource-id cluster:myscalablecluster \
  --service-namespace rds \
  --scalable-dimension rds:cluster:ReadReplicaCount \
  --target-tracking-scaling-policy-configuration file://config.json
```

For Windows:

```
aws application-autoscaling put-scaling-policy ^
  --policy-name myscalablepolicy ^
  --policy-type TargetTrackingScaling ^
  --resource-id cluster:myscalablecluster ^
  --service-namespace rds ^
  --scalable-dimension rds:cluster:ReadReplicaCount ^
  --target-tracking-scaling-policy-configuration file://config.json
```

RDS API

To apply a scaling policy to your Aurora DB cluster with the Application Auto Scaling API, use the [PutScalingPolicy](#) Application Auto Scaling API operation with the following parameters:

- **PolicyName** – The name of the scaling policy.
- **ServiceNamespace** – Set this value to `rds`.
- **ResourceID** – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`.
- **ScalableDimension** – Set this value to `rds:cluster:ReadReplicaCount`.
- **PolicyType** – Set this value to `TargetTrackingScaling`.
- **TargetTrackingScalingPolicyConfiguration** – The target-tracking scaling policy configuration to use for the Aurora DB cluster.

Example

In the following example, you apply a target-tracking scaling policy named `myscalablepolicy` to an Aurora DB cluster named `myscalablecluster` with Application Auto Scaling. You use a policy configuration based on the `RDSReaderAverageCPUUtilization` predefined metric.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.PutScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "rds",
    "ResourceId": "cluster:myscalablecluster",
    "ScalableDimension": "rds:cluster:ReadReplicaCount",
    "PolicyType": "TargetTrackingScaling",
    "TargetTrackingScalingPolicyConfiguration": {
        "TargetValue": 40.0,
        "PredefinedMetricSpecification":
        {
            "PredefinedMetricType": "RDSReaderAverageCPUUtilization"
        }
    }
}
```

Editing a scaling policy

You can edit a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Editing a scaling policy using the AWS Management Console

You can edit a scaling policy by using the AWS Management Console.

To edit an auto scaling policy for an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora DB cluster whose auto scaling policy you want to edit.
4. Choose the **Logs & events** tab.
5. In the **Auto scaling policies** section, choose the auto scaling policy, and then choose **Edit**.
6. Make changes to the policy.
7. Choose **Save**.

The following is a sample **Edit Auto Scaling policy** dialog box.

AWSServiceRoleForApplicationAutoScaling_RDSCluster

Target metric

Only one Aurora Auto Scaling policy is allowed for one metric.

Average CPU utilization of Aurora Replicas [View metric](#)

Average connections of Aurora Replicas [View metric](#)

Target value

Specify the desired value for the selected metric. Aurora Replicas will be added or removed to keep the metric close to the specified value.

50

%

► Additional configuration

Cluster capacity details

Capacity values specified below apply to all the Aurora Auto Scaling policies for the DB cluster.

Minimum capacity

Specify the minimum number of Aurora Replicas to maintain.

1

Aurora Replicas

Maximum capacity

Specify the maximum number of Aurora Replicas to maintain. Up to 15 Aurora Replicas are supported.

6

Aurora Replicas

Changes to the capacity values will be applied to all the Auto Scaling policies for this DB cluster.

Editing a scaling policy using the AWS CLI or the Application Auto Scaling API

You can use the AWS CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:

- When using the AWS CLI, specify the name of the policy you want to edit in the `--policy-name` parameter. Specify new values for the parameters you want to change.
- When using the Application Auto Scaling API, specify the name of the policy you want to edit in the `PolicyName` parameter. Specify new values for the parameters you want to change.

For more information, see [Applying a scaling policy to an Aurora DB cluster \(p. 436\)](#).

Deleting a scaling policy

You can delete a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Deleting a scaling policy using the AWS Management Console

You can delete a scaling policy by using the AWS Management Console.

To delete an auto scaling policy for an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora DB cluster whose auto scaling policy you want to delete.
4. Choose the **Logs & events** tab.
5. In the **Auto scaling policies** section, choose the auto scaling policy, and then choose **Delete**.

Deleting a scaling policy using the AWS CLI or the Application Auto Scaling API

You can use the AWS CLI or the Application Auto Scaling API to delete a scaling policy from an Aurora DB cluster.

AWS CLI

To delete a scaling policy from your Aurora DB cluster, use the `delete-scaling-policy` AWS CLI command with the following parameters:

- `--policy-name` – The name of the scaling policy.
- `--resource-id` – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`.
- `--service-namespace` – Set this value to `rds`.
- `--scalable-dimension` – Set this value to `rds:cluster:ReadReplicaCount`.

Example

In the following example, you delete a target-tracking scaling policy named `myscalablepolicy` from an Aurora DB cluster named `myscalablecluster`.

For Linux, macOS, or Unix:

```
aws application-autoscaling delete-scaling-policy \
--policy-name myscalablepolicy \
--resource-id cluster:myscalablecluster \
--service-namespace rds \
```

```
--scalable-dimension rds:cluster:ReadReplicaCount \
```

For Windows:

```
aws application-autoscaling delete-scaling-policy ^
--policy-name myscalablepolicy ^
--resource-id cluster:myscalablecluster ^
--service-namespace rds ^
--scalable-dimension rds:cluster:ReadReplicaCount ^
```

RDS API

To delete a scaling policy from your Aurora DB cluster, use the [DeleteScalingPolicy](#) the Application Auto Scaling API operation with the following parameters:

- **PolicyName** – The name of the scaling policy.
- **ServiceNamespace** – Set this value to `rds`.
- **ResourceId** – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`.
- **ScalableDimension** – Set this value to `rds:cluster:ReadReplicaCount`.

Example

In the following example, you delete a target-tracking scaling policy named `myscalablepolicy` from an Aurora DB cluster named `myscalablecluster` with the Application Auto Scaling API.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "rds",
    "ResourceId": "cluster:myscalablecluster",
    "ScalableDimension": "rds:cluster:ReadReplicaCount"
}
```

DB instance IDs and tagging

When a replica is added by Aurora Auto Scaling, its DB instance ID is prefixed by `application-autoscaling-`, for example, `application-autoscaling-61aabbc-4e2f-4c65-b620-ab7421abc123`.

The following tag is automatically added to the DB instance. You can view it on the **Tags** tab of the DB instance detail page.

Tag	Value
application-autoscaling:resourceId	cluster:mynewcluster-cluster

For more information on Amazon RDS resource tags, see [Tagging Amazon RDS resources \(p. 474\)](#).

Using machine learning (ML) capabilities with Amazon Aurora

Following, you can find a description of how to use machine learning (ML) capabilities in your Aurora database applications. This feature simplifies developing database applications that use the Amazon SageMaker and Amazon Comprehend services to perform predictions. In ML terminology, these predictions are known as *inferences*.

This feature is suitable for many kinds of quick predictions. Examples include low-latency, real-time use cases such as fraud detection, ad targeting, and product recommendations. The queries pass customer profile, shopping history, and product catalog data to an SageMaker model. Then your application gets product recommendations returned as query results.

To use this feature, it helps for your organization to already have the appropriate ML models, notebooks, and so on available in the Amazon machine learning services. You can divide the database knowledge and ML knowledge among the members of your team. The database developers can focus on the SQL and database side of your application. The Aurora Machine Learning feature enables the application to use ML processing through the familiar database interface of stored function calls.

Topics

- [Using machine learning \(ML\) with Aurora MySQL \(p. 1020\)](#)
- [Using machine learning \(ML\) with Aurora PostgreSQL \(p. 1494\)](#)

Maintaining an Amazon Aurora DB cluster

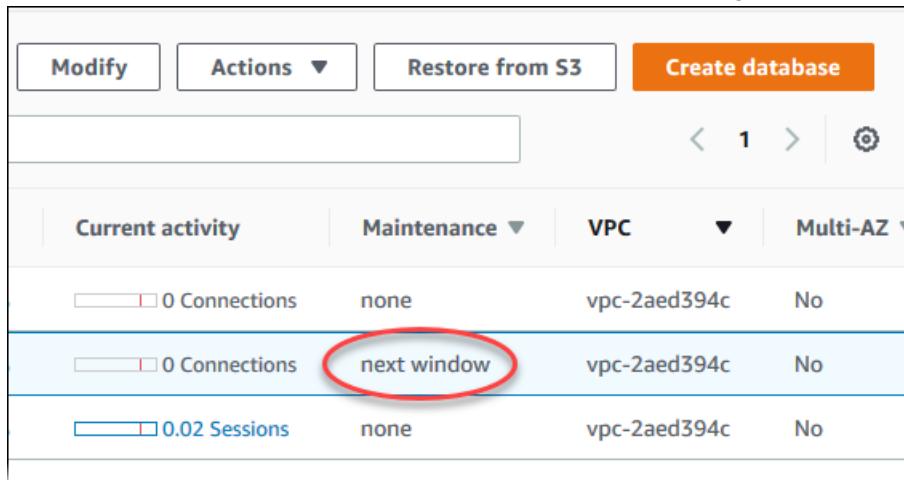

Periodically, Amazon RDS performs maintenance on Amazon RDS resources. Maintenance most often involves updates to the DB cluster's underlying hardware, underlying operating system (OS), or database engine version. Updates to the operating system most often occur for security issues and should be done as soon as possible.

Some maintenance items require that Amazon RDS take your DB cluster offline for a short time. Maintenance items that require a resource to be offline include required operating system or database patching. Required patching is automatically scheduled only for patches that are related to security and instance reliability. Such patching occurs infrequently (typically once every few months) and seldom requires more than a fraction of your maintenance window.

Deferred DB cluster and instance modifications that you have chosen not to apply immediately are also applied during the maintenance window. For example, you might choose to change DB instance classes or cluster or DB parameter groups during the maintenance window. Such modifications that you specify using the **pending reboot** setting don't show up in the **Pending maintenance** list. For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

Viewing pending maintenance

You can view whether a maintenance update is available for your DB cluster by using the RDS console, the AWS CLI, or the Amazon RDS API. If an update is available, it is indicated in the **Maintenance** column for the DB cluster on the Amazon RDS console, as shown following.

The screenshot shows a table in the Amazon RDS console. The columns are: Current activity, Maintenance, VPC, and Multi-AZ. There are three rows of data:

Current activity	Maintenance	VPC	Multi-AZ
0 Connections	none	vpc-2aed394c	No
0 Connections	next window	vpc-2aed394c	No
0.02 Sessions	none	vpc-2aed394c	No

If no maintenance update is available for a DB cluster, the column value is **none** for it.

If a maintenance update is available for a DB cluster, the following column values are possible:

- **required** – The maintenance action will be applied to the resource and can't be deferred indefinitely.
- **available** – The maintenance action is available, but it will not be applied to the resource automatically. You can apply it manually.
- **next window** – The maintenance action will be applied to the resource during the next maintenance window.
- **In progress** – The maintenance action is in the process of being applied to the resource.

If an update is available, you can take one of the actions:

- If the maintenance value is **next window**, defer the maintenance items by choosing **Defer upgrade** from **Actions**. You can't defer a maintenance action if it has already started.
- Apply the maintenance items immediately.
- Schedule the maintenance items to start during your next maintenance window.
- Take no action.

Note

Certain OS updates are marked as **required**. If you defer a required update, you get a notice from Amazon RDS indicating when the update will be performed. Other updates are marked as **available**, and these you can defer indefinitely.

To take an action, choose the DB cluster to show its details, then choose **Maintenance & backups**. The pending maintenance items appear.

The screenshot shows the AWS RDS console with the 'Maintenance & backups' tab selected. In the 'Maintenance' section, it shows that 'Auto minor version upgrade' is 'Enabled'. Below this, under 'Pending maintenance (1)', there is a table with one item:

Description	Type	Status	Apply date
Automatic minor version upgrade to postgres 9.6.11	db-upgrade	next window	February 25th 2019, 3:28:00 am UTC-8 (local)

There are buttons to 'Apply now' or 'Apply at next maintenance window'.

The maintenance window determines when pending operations start, but doesn't limit the total run time of these operations. Maintenance operations aren't guaranteed to finish before the maintenance window ends, and can continue beyond the specified end time. For more information, see [The Amazon RDS maintenance window \(p. 446\)](#).

For information about updates to Amazon Aurora engines and instructions for upgrading and patching them, see [Database engine updates for Amazon Aurora MySQL \(p. 1082\)](#) and [Amazon Aurora PostgreSQL updates \(p. 1597\)](#).

You can also view whether a maintenance update is available for your DB cluster by running the `describe-pending-maintenance-actions` AWS CLI command.

Applying updates for a DB cluster

With Amazon RDS, you can choose when to apply maintenance operations. You can decide when Amazon RDS applies updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API.

Console

To manage an update for a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster that has a required update.
4. For **Actions**, choose one of the following:
 - **Upgrade now**
 - **Upgrade at next window**

Note

If you choose **Upgrade at next window** and later want to delay the update, you can choose **Defer upgrade**. You can't defer a maintenance action if it has already started. To cancel a maintenance action, modify the DB instance and disable **Auto minor version upgrade**.

AWS CLI

To apply a pending update to a DB cluster, use the [apply-pending-maintenance-action](#) AWS CLI command.

Example

For Linux, macOS, or Unix:

```
aws rds apply-pending-maintenance-action \
    --resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db \
    --apply-action system-update \
    --opt-in-type immediate
```

For Windows:

```
aws rds apply-pending-maintenance-action ^
    --resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db ^
    --apply-action system-update ^
    --opt-in-type immediate
```

Note

To defer a maintenance action, specify `undo-opt-in` for `--opt-in-type`. You can't specify `undo-opt-in` for `--opt-in-type` if the maintenance action has already started. To cancel a maintenance action, run the [modify-db-instance](#) AWS CLI command and specify `--no-auto-minor-version-upgrade`.

To return a list of resources that have at least one pending update, use the [describe-pending-maintenance-actions](#) AWS CLI command.

Example

For Linux, macOS, or Unix:

```
aws rds describe-pending-maintenance-actions \
--resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db
```

For Windows:

```
aws rds describe-pending-maintenance-actions ^
--resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db
```

You can also return a list of resources for a DB cluster by specifying the `--filters` parameter of the `describe-pending-maintenance-actions` AWS CLI command. The format for the `--filters` command is `Name=filter-name,Value=resource-id,....`

The following are the accepted values for the `Name` parameter of a filter:

- `db-instance-id` – Accepts a list of DB instance identifiers or Amazon Resource Names (ARNs). The returned list only includes pending maintenance actions for the DB instances identified by these identifiers or ARNs.
- `db-cluster-id` – Accepts a list of DB cluster identifiers or ARNs for Amazon Aurora. The returned list only includes pending maintenance actions for the DB clusters identified by these identifiers or ARNs.

For example, the following example returns the pending maintenance actions for the `sample-cluster1` and `sample-cluster2` DB clusters.

Example

For Linux, macOS, or Unix:

```
aws rds describe-pending-maintenance-actions \
--filters Name=db-cluster-id,Values=sample-cluster1,sample-cluster2
```

For Windows:

```
aws rds describe-pending-maintenance-actions ^
--filters Name=db-cluster-id,Values=sample-cluster1,sample-cluster2
```

RDS API

To apply an update to a DB cluster, call the Amazon RDS API [ApplyPendingMaintenanceAction](#) operation.

To return a list of resources that have at least one pending update, call the Amazon RDS API [DescribePendingMaintenanceActions](#) operation.

The Amazon RDS maintenance window

Every DB cluster has a weekly maintenance window during which any system changes are applied. You can think of the maintenance window as an opportunity to control when modifications and software patching occur, in the event either are requested or required. If a maintenance event is scheduled for a given week, it is initiated during the 30-minute maintenance window you identify. Most maintenance events also complete during the 30-minute maintenance window, although larger maintenance events may take more than 30 minutes to complete.

The 30-minute maintenance window is selected at random from an 8-hour block of time per region. If you don't specify a preferred maintenance window when you create the DB cluster, then Amazon RDS assigns a 30-minute maintenance window on a randomly selected day of the week.

RDS will consume some of the resources on your DB cluster while maintenance is being applied. You might observe a minimal effect on performance. For a DB instance, on rare occasions, a Multi-AZ failover might be required for a maintenance update to complete.

Following, you can find the time blocks for each region from which default maintenance windows are assigned.

Region Name	Region	Time Block
US East (Ohio)	us-east-2	03:00–11:00 UTC
US East (N. Virginia)	us-east-1	03:00–11:00 UTC
US West (N. California)	us-west-1	06:00–14:00 UTC
US West (Oregon)	us-west-2	06:00–14:00 UTC
Africa (Cape Town)	af-south-1	03:00–11:00 UTC
Asia Pacific (Hong Kong)	ap-east-1	06:00–14:00 UTC
Asia Pacific (Jakarta)	ap-southeast-3	08:00–16:00 UTC
Asia Pacific (Mumbai)	ap-south-1	06:00–14:00 UTC
Asia Pacific (Osaka)	ap-northeast-3	22:00–23:59 UTC
Asia Pacific (Seoul)	ap-northeast-2	13:00–21:00 UTC
Asia Pacific (Singapore)	ap-southeast-1	14:00–22:00 UTC
Asia Pacific (Sydney)	ap-southeast-2	12:00–20:00 UTC
Asia Pacific (Tokyo)	ap-northeast-1	13:00–21:00 UTC
Canada (Central)	ca-central-1	03:00–11:00 UTC
China (Beijing)	cn-north-1	06:00–14:00 UTC
China (Ningxia)	cn-northwest-1	06:00–14:00 UTC
Europe (Frankfurt)	eu-central-1	21:00–05:00 UTC
Europe (Ireland)	eu-west-1	22:00–06:00 UTC
Europe (London)	eu-west-2	22:00–06:00 UTC
Europe (Paris)	eu-west-3	23:59–07:29 UTC
Europe (Milan)	eu-south-1	02:00–10:00 UTC
Europe (Stockholm)	eu-north-1	23:00–07:00 UTC
Middle East (Bahrain)	me-south-1	06:00–14:00 UTC
South America (São Paulo)	sa-east-1	00:00–08:00 UTC

Region Name	Region	Time Block
AWS GovCloud (US-East)	us-gov-east-1	17:00–01:00 UTC
AWS GovCloud (US-West)	us-gov-west-1	06:00–14:00 UTC

Adjusting the preferred DB cluster maintenance window

The Aurora DB cluster maintenance window should fall at the time of lowest usage and thus might need modification from time to time. Your DB cluster is unavailable during this time only if the updates that are being applied require an outage. The outage is for the minimum amount of time required to make the necessary updates.

Console

To adjust the preferred DB cluster maintenance window

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster for which you want to change the maintenance window.
4. Choose **Modify**.
5. In the **Maintenance** section, update the maintenance window.
6. Choose **Continue**.

On the confirmation page, review your changes.

7. To apply the changes to the maintenance window immediately, choose **Immediately** in the **Schedule of modifications** section.
8. Choose **Modify cluster** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To adjust the preferred DB cluster maintenance window, use the AWS CLI `modify-db-cluster` command with the following parameters:

- `--db-cluster-identifier`
- `--preferred-maintenance-window`

Example

The following code example sets the maintenance window to Tuesdays from 4:00–4:30 AM UTC.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
--db-cluster-identifier my-cluster \
```

```
--preferred-maintenance-window Tue:04:00-Tue:04:30
```

For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier my-cluster ^
--preferred-maintenance-window Tue:04:00-Tue:04:30
```

RDS API

To adjust the preferred DB cluster maintenance window, use the Amazon RDS [ModifyDBCluster](#) API operation with the following parameters:

- `DBClusterIdentifier`
- `PreferredMaintenanceWindow`

Automatic minor version upgrades for Aurora DB clusters

The **Auto minor version upgrade** setting specifies whether Aurora automatically applies upgrades to your cluster. These upgrades include patch levels containing bug fixes, and new minor versions containing additional features. They don't include any incompatible changes.

Note

This setting is enabled by default. For each new cluster, choose the appropriate value for this setting based on its importance, expected lifetime, and the amount of verification testing that you do after each upgrade.

For instructions about turning this setting on or off, see [Settings for Amazon Aurora \(p. 375\)](#). In particular, make sure to apply the same setting to all DB instances in the cluster. If any DB instance in your cluster has this setting turned off, the cluster isn't automatically upgraded.

For more information about engine updates for Aurora PostgreSQL, see [Amazon Aurora PostgreSQL updates \(p. 1597\)](#).

For more information about the **Auto minor version upgrade** setting for Aurora MySQL, see [Enabling automatic upgrades between minor Aurora MySQL versions \(p. 1089\)](#). For general information about engine updates for Aurora MySQL, see [Database engine updates for Amazon Aurora MySQL \(p. 1082\)](#).

Choosing the frequency of Aurora MySQL maintenance updates

You can control whether Aurora MySQL upgrades happen frequently or rarely for each DB cluster. The best choice depends on your usage of Aurora MySQL and the priorities for your applications that run on Aurora. For information about the Aurora MySQL long-term stability (LTS) releases that require less frequent upgrades, see [Aurora MySQL long-term support \(LTS\) releases \(p. 1085\)](#).

You might choose to upgrade an Aurora MySQL cluster rarely if some or all of the following conditions apply:

- Your testing cycle for your application takes a long time for each update to the Aurora MySQL database engine.
- You have many DB clusters or many applications all running on the same Aurora MySQL version. You prefer to upgrade all of your DB clusters and associated applications at the same time.

- You use both Aurora MySQL and RDS for MySQL, and you prefer to keep the Aurora MySQL clusters and RDS for MySQL DB instances compatible with the same level of MySQL.
- Your Aurora MySQL application is in production or is otherwise business-critical. You can't afford downtime for upgrades outside of rare occurrences for critical patches.
- Your Aurora MySQL application isn't limited by performance issues or feature gaps that are addressed in subsequent Aurora MySQL versions.

If the preceding factors apply to your situation, you can limit the number of forced upgrades for an Aurora MySQL DB cluster. You do so by choosing a specific Aurora MySQL version known as the "Long-Term Support" (LTS) version when you create or upgrade that DB cluster. Doing so minimizes the number of upgrade cycles, testing cycles, and upgrade-related outages for that DB cluster.

You might choose to upgrade an Aurora MySQL cluster frequently if some or all of the following conditions apply:

- The testing cycle for your application is straightforward and brief.
- Your application is still in the development stage.
- Your database environment uses a variety of Aurora MySQL versions, or Aurora MySQL and RDS for MySQL versions. Each Aurora MySQL cluster has its own upgrade cycle.
- You are waiting for specific performance or feature improvements before you increase your usage of Aurora MySQL.

If the preceding factors apply to your situation, you can enable Aurora to apply important upgrades more frequently by upgrading an Aurora MySQL DB cluster to a more recent Aurora MySQL version than the LTS version. Doing so makes the latest performance enhancements, bug fixes, and features available to you more quickly.

Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance

You might need to reboot your DB cluster or some instances within the cluster, usually for maintenance reasons. For example, suppose that you modify the parameters within a parameter group or associate a different parameter group with your cluster. In these cases, you must reboot the cluster for the changes to take effect. Similarly, you might reboot one or more reader DB instances within the cluster. You can arrange the reboot operations for individual instances to minimize downtime for the entire cluster.

The time required to reboot each DB instance in your cluster depends on the database activity at the time of reboot. It also depends on the recovery process of your specific DB engine. If it's practical, reduce database activity on that particular instance before starting the reboot process. Doing so can reduce the time needed to restart the database.

You can only reboot each DB instance in your cluster when it's in the available state. A DB instance can be unavailable for several reasons. These include the cluster being stopped state, a modification being applied to the instance, and a maintenance-window action such as a version upgrade.

Rebooting a DB instance restarts the database engine process. Rebooting a DB instance results in a momentary outage, during which the DB instance status is set to *rebooting*.

Note

If a DB instance isn't using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of **pending-reboot**. The **pending-reboot** parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance. For more information about parameter groups, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#).

Topics

- [Rebooting a DB instance within an Aurora cluster \(p. 451\)](#)
- [Rebooting an Aurora cluster \(Aurora PostgreSQL and Aurora MySQL before version 2.10\) \(p. 452\)](#)
- [Rebooting an Aurora MySQL cluster \(version 2.10 and higher\) \(p. 452\)](#)
- [Checking uptime for Aurora clusters and instances \(p. 453\)](#)
- [Examples of Aurora reboot operations \(p. 455\)](#)

Rebooting a DB instance within an Aurora cluster

This procedure is the most important operation that you take when performing reboots with Aurora. Many of the maintenance procedures involve rebooting one or more Aurora DB instances in a particular order.

Console

To reboot a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to reboot.
3. For **Actions**, choose **Reboot**.
The **Reboot DB Instance** page appears.
4. Choose **Reboot** to reboot your DB instance.

Or choose **Cancel**.

AWS CLI

To reboot a DB instance by using the AWS CLI, call the `reboot-db-instance` command.

Example

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance \  
  --db-instance-identifier mydbinstance
```

For Windows:

```
aws rds reboot-db-instance ^  
  --db-instance-identifier mydbinstance
```

RDS API

To reboot a DB instance by using the Amazon RDS API, call the `RebootDBInstance` operation.

Rebooting an Aurora cluster (Aurora PostgreSQL and Aurora MySQL before version 2.10)

In Aurora PostgreSQL-Compatible Edition, in Aurora MySQL-Compatible Edition version 1, and in Aurora MySQL before version 2.10, you reboot an entire Aurora DB cluster by rebooting the writer DB instance of that cluster. To do so, follow the procedure in [Rebooting a DB instance within an Aurora cluster \(p. 451\)](#).

Rebooting the writer DB instance also initiates a reboot for each reader DB instance in the cluster. That way, any cluster-wide parameter changes are applied to all DB instances at the same time. However, the reboot of all DB instances causes a brief outage for the cluster. The reader DB instances remain unavailable until the writer DB instance finishes rebooting and becomes available.

In the RDS console, the writer DB instance has the value **Writer** under the **Role** column on the **Databases** page. In the RDS CLI, the output of the `describe-db-clusters` command includes a section `DBCClusterMembers`. The `DBCClusterMembers` element representing the writer DB instance has a value of `true` for the `IsClusterWriter` field.

Important

In Aurora MySQL 2.10 and higher, the reboot behavior is different: the reader DB instances typically remain available while you reboot the writer instance. Then you can reboot the reader instances at a convenient time. You can reboot the reader instances on a staggered schedule if you want some reader instances to always be available. For more information, see [Rebooting an Aurora MySQL cluster \(version 2.10 and higher\) \(p. 452\)](#).

Rebooting an Aurora MySQL cluster (version 2.10 and higher)

In Aurora MySQL version 2.10 and higher, you can reboot the writer instance of your Aurora MySQL cluster without rebooting the reader instances in the cluster. Doing so can help maintain high availability

of the cluster for read operations while you reboot the writer instance. You can reboot the reader instances later, on a schedule that's convenient for you. For example, for a production cluster, you might reboot the reader instances one at a time, starting only after the reboot of the primary instance is finished. For each DB instance that you reboot, follow the procedure in [Rebooting a DB instance within an Aurora cluster \(p. 451\)](#).

Before Aurora MySQL 2.10, rebooting the primary instance caused a reboot for each reader instance at the same time. If your Aurora MySQL cluster is running an older version, use the reboot procedure in [Rebooting an Aurora cluster \(Aurora PostgreSQL and Aurora MySQL before version 2.10\) \(p. 452\)](#) instead.

Important

The change to reboot behavior in Aurora MySQL 2.10 and higher is different for Aurora global databases. If you reboot the writer instance for the primary cluster in an Aurora global database, the reader instances in the primary cluster remain available. However, the DB instances in any secondary clusters reboot at the same time.

You frequently reboot the cluster after making changes to cluster parameter groups. You make parameter changes by following the procedures in [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#). Suppose that you reboot the writer DB instance in an Aurora MySQL cluster to apply changes to cluster parameters. Some or all of the reader DB instances might continue using the old parameter settings. However, the different parameter settings don't affect the data integrity of the cluster. Any cluster parameters that affect the organization of data files are only used by the writer DB instance. For example, you can update cluster parameters such as `binlog_format` and `innodb_purge_threads` on the writer instance before the reader instances. Only the writer instance is writing binary logs and purging undo records.

For parameters that change how queries interpret SQL statements or query output, you might need to take care to reboot the reader instances immediately. You do this to avoid unexpected application behavior during queries. For example, suppose that you change the `lower_case_table_names` parameter and reboot the writer instance. In this case, the reader instances might not be able to access a newly created table until they are all rebooted.

For a list of all the Aurora MySQL cluster parameters, see [Cluster-level parameters \(p. 1043\)](#).

Tip

Aurora MySQL might still reboot some of the reader instances along with the writer instance if your cluster is processing a workload with high throughput.

The reduction in the number of reboots applies during failover operations also. Aurora MySQL only restarts the writer DB instance and the failover target during a failover. Other reader DB instances in the cluster remain available to continue processing queries through connections to the reader endpoint. Thus, you can improve availability during a failover by having more than one reader DB instance in a cluster.

Checking uptime for Aurora clusters and instances

You can check and monitor the length of time since the last reboot for each DB instance in your Aurora cluster. The Amazon CloudWatch metric `EngineUptime` reports the number of seconds since the last time a DB instance was started. You can examine this metric at a point in time to find out the uptime for the DB instance. You can also monitor this metric over time to detect when the instance is rebooted.

You can also examine the `EngineUptime` metric at the cluster level. The `Minimum` and `Maximum` dimensions report the smallest and largest uptime values for all DB instances in the cluster. To check the most recent time when any reader instance in a cluster was rebooted, or restarted for another reason, monitor the cluster-level metric using the `Minimum` dimension. To check which instance in the cluster has gone the longest without a reboot, monitor the cluster-level metric using the `Maximum` dimension. For example, you might want to confirm that all DB instances in the cluster were rebooted after a configuration change.

Tip

For long-term monitoring, we recommend monitoring the `EngineUptime` metric for individual instances instead of at the cluster level. The cluster-level `EngineUptime` metric is set to zero when a new DB instance is added to the cluster. Such cluster changes can happen as part of maintenance and scaling operations such as those performed by Auto Scaling.

The following CLI examples show how to examine the `EngineUptime` metric for the writer and reader instances in a cluster. The examples use a cluster named `tpch100g`. This cluster has a writer DB instance `instance-1234`. It also has two reader DB instances, `instance-7448` and `instance-6305`.

First, the `reboot-db-instance` command reboots one of the reader instances. The `wait` command waits until the instance is finished rebooting.

```
$ aws rds reboot-db-instance --db-instance-identifier instance-6305
{
    "DBInstance": {
        "DBInstanceIdentifier": "instance-6305",
        "DBInstanceState": "rebooting",
    }
...
$ aws rds wait db-instance-available --db-instance-id instance-6305
```

The CloudWatch `get-metric-statistics` command examines the `EngineUptime` metric over the last five minutes at one-minute intervals. The uptime for the `instance-6305` instance is reset to zero and begins counting upwards again. This AWS CLI example for Linux uses `$()` variable substitution to insert the appropriate timestamps into the CLI commands. It also uses the Linux `sort` command to order the output by the time the metric was collected. That timestamp value is the third field in each line of output.

```
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
--period 60 --namespace "AWS/RDS" --statistics Maximum \
--dimensions Name=DBInstanceIdentifier,Value=instance-6305 --output text \
| sort -k 3
EngineUptime
DATAPOINTS 231.0 2021-03-16T18:19:00+00:00 Seconds
DATAPOINTS 291.0 2021-03-16T18:20:00+00:00 Seconds
DATAPOINTS 351.0 2021-03-16T18:21:00+00:00 Seconds
DATAPOINTS 411.0 2021-03-16T18:22:00+00:00 Seconds
DATAPOINTS 471.0 2021-03-16T18:23:00+00:00 Seconds
```

The minimum uptime for the cluster is reset to zero because one of the instances in the cluster was rebooted. The maximum uptime for the cluster isn't reset because at least one of the DB instances in the cluster remained available.

```
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
--period 60 --namespace "AWS/RDS" --statistics Minimum \
--dimensions Name=DBClusterIdentifier,Value=tpch100g --output text \
| sort -k 3
EngineUptime
DATAPOINTS 63099.0 2021-03-16T18:12:00+00:00 Seconds
DATAPOINTS 63159.0 2021-03-16T18:13:00+00:00 Seconds
DATAPOINTS 63219.0 2021-03-16T18:14:00+00:00 Seconds
DATAPOINTS 63279.0 2021-03-16T18:15:00+00:00 Seconds
DATAPOINTS 51.0 2021-03-16T18:16:00+00:00 Seconds

$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
--period 60 --namespace "AWS/RDS" --statistics Maximum \
--dimensions Name=DBClusterIdentifier,Value=tpch100g --output text \
```

```
| sort -k 3
EngineUptime
DATAPOINTS 63389.0 2021-03-16T18:16:00+00:00 Seconds
DATAPOINTS 63449.0 2021-03-16T18:17:00+00:00 Seconds
DATAPOINTS 63509.0 2021-03-16T18:18:00+00:00 Seconds
DATAPOINTS 63569.0 2021-03-16T18:19:00+00:00 Seconds
DATAPOINTS 63629.0 2021-03-16T18:20:00+00:00 Seconds
```

Then another `reboot-db-instance` command reboots the writer instance of the cluster. Another `wait` command pauses until the writer instance is finished rebooting.

```
$ aws rds reboot-db-instance --db-instance-identifier instance-1234
{
  "DBInstanceIdentifier": "instance-1234",
  "DBInstanceState": "rebooting",
  ...
$ aws rds wait db-instance-available --db-instance-id instance-1234
```

Now the `EngineUptime` metric for the writer instance shows that the instance `instance-1234` was rebooted recently. The reader instance `instance-6305` was also rebooted automatically along with the writer instance. This cluster is running Aurora MySQL 2.09, which doesn't keep the reader instances running as the writer instance reboots.

```
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
--period 60 --namespace "AWS/RDS" --statistics Maximum \
--dimensions Name=DBInstanceIdentifier,Value=instance-1234 --output text \
| sort -k 3

```

Examples of Aurora reboot operations

The following Aurora MySQL examples show different combinations of reboot operations for reader and writer DB instances in an Aurora DB cluster. After each reboot, SQL queries demonstrate the uptime for the instances in the cluster.

Topics

- [Finding the writer and reader instances for an Aurora cluster \(p. 456\)](#)
- [Rebooting a single reader instance \(p. 456\)](#)
- [Rebooting the writer instance \(p. 457\)](#)
- [Rebooting the writer and readers independently \(p. 458\)](#)
- [Applying a cluster parameter change to an Aurora MySQL version 2.10 cluster \(p. 461\)](#)

Finding the writer and reader instances for an Aurora cluster

In an Aurora MySQL cluster with multiple DB instances, it's important to know which one is the writer and which ones are the readers. The writer and reader instances also can switch roles when a failover operation happens. Thus, it's best to perform a check like the following before doing any operation that requires a writer or reader instance. In this case, the `False` values for `IsClusterWriter` identify the reader instances, `instance-6305` and `instance-7448`. The `True` value identifies the writer instance, `instance-1234`.

```
$ aws rds describe-db-clusters --db-cluster-id tpch100g \
    --query "[].['Cluster:',DBClusterIdentifier,DBClusterMembers[*]].
    ['Instance:',DBInstanceIdentifier,IsClusterWriter]]" \
    --output text
Cluster:      tpch100g
Instance:     instance-6305      False
Instance:     instance-7448      False
Instance:     instance-1234      True
```

Before we start the examples of rebooting, the writer instance has an uptime of approximately one week. The SQL query in this example shows a MySQL-specific way to check the uptime. You might use this technique in a database application. For another technique that uses the AWS CLI and works for both Aurora engines, see [Checking uptime for Aurora clusters and instances \(p. 453\)](#).

```
$ mysql -h instance-7448.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
       -> time_format(sec_to_time(variable_value),'%H %im') as "Uptime"
       -> from performance_schema.global_status
       -> where variable_name='Uptime';
+-----+-----+
| Last Startup          | Uptime   |
+-----+-----+
| 2021-03-08 17:49:06.000000 | 174h 42m|
+-----+-----+
```

Rebooting a single reader instance

This example reboots one of the reader DB instances. Perhaps this instance was overloaded by a huge query or many concurrent connections. Or perhaps it fell behind the writer instance because of a network issue. After starting the reboot operation, the example uses a `wait` command to pause until the instance becomes available. By that point, the instance has an uptime of a few minutes.

```
$ aws rds reboot-db-instance --db-instance-identifier instance-6305
{
    "DBInstance": {
        "DBInstanceIdentifier": "instance-6305",
        "DBInstanceState": "rebooting",
        ...
    }
}
$ aws rds wait db-instance-available --db-instance-id instance-6305
$ mysql -h instance-6305.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
       -> time_format(sec_to_time(variable_value),'%H %im') as "Uptime"
       -> from performance_schema.global_status
       -> where variable_name='Uptime';
+-----+-----+
| Last Startup          | Uptime   |
+-----+-----+
```

```
+-----+-----+
| 2021-03-16 00:35:02.000000 | 00h 03m |
+-----+-----+
```

Rebooting the reader instance didn't affect the uptime of the writer instance. It still has an uptime of about one week.

```
$ mysql -h instance-7448.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
   -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
   -> from performance_schema.global_status where variable_name='Uptime';
+-----+-----+
| Last Startup           | Uptime    |
+-----+-----+
| 2021-03-08 17:49:06.000000 | 174h 49m |
+-----+-----+
```

Rebooting the writer instance

This example reboots the writer instance. This cluster is running Aurora MySQL version 2.09. Because the Aurora MySQL version is lower than 2.10, rebooting the writer instance also reboots any reader instances in the cluster.

A wait command pauses until the reboot is finished. Now the uptime for that instance is reset to zero. It's possible that a reboot operation might take substantially different times for writer and reader DB instances. The writer and reader DB instances perform different kinds of cleanup operations depending on their roles.

```
$ aws rds reboot-db-instance --db-instance-identifier instance-1234
{
    "DBInstance": {
        "DBInstanceIdentifier": "instance-1234",
        "DBInstanceStatus": "rebooting",
        ...
    }
}
$ aws rds wait db-instance-available --db-instance-id instance-1234
$ mysql -h instance-1234.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
   -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
   -> from performance_schema.global_status where variable_name='Uptime';
+-----+-----+
| Last Startup           | Uptime    |
+-----+-----+
| 2021-03-16 00:40:27.000000 | 00h 00m |
+-----+-----+
```

After the reboot for the writer DB instance, both of the reader DB instances also have their uptime reset. Rebooting the writer instance caused the reader instances to reboot also. This behavior applies to Aurora PostgreSQL clusters and to Aurora MySQL clusters before version 2.10.

```
$ mysql -h instance-7448.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
   -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
   -> from performance_schema.global_status where variable_name='Uptime';
+-----+-----+
| Last Startup           | Uptime    |
+-----+-----+
```

```
+-----+-----+
| 2021-03-16 00:40:35.000000 | 00h 00m |
+-----+-----+
$ mysql -h instance-6305.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
-> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
-> from performance_schema.global_status where variable_name='Uptime';
+-----+-----+
| Last Startup           | Uptime   |
+-----+-----+
| 2021-03-16 00:40:33.000000 | 00h 01m |
+-----+-----+
```

Rebooting the writer and readers independently

These next examples show a cluster that runs Aurora MySQL version 2.10. In this Aurora MySQL version and higher, you can reboot the writer instance without causing reboots for all the reader instances. That way, your query-intensive applications don't experience any outage when you reboot the writer instance. You can reboot the reader instances later. You might do those reboots at a time of low query traffic. You might also reboot the reader instances one at a time. That way, at least one reader instance is always available for the query traffic of your application.

The following example uses a cluster named `cluster-2393`, running Aurora MySQL version `5.7.mysql_aurora.2.10.0`. This cluster has a writer instance named `instance-9404` and three reader instances named `instance-6772`, `instance-2470`, and `instance-5138`.

```
$ aws rds describe-db-clusters --db-cluster-id cluster-2393 \
--query "[*].[['Cluster:',DBClusterIdentifier,DBClusterMembers[*]].\n['Instance:',DBInstanceIdentifier,IsClusterWriter]]" \
--output text
Cluster:      cluster-2393
Instance:     instance-5138      False
Instance:     instance-2470      False
Instance:     instance-6772      False
Instance:     instance-9404      True
```

Checking the `uptime` value of each database instance through the `mysql` command shows that each one has roughly the same uptime. For example, here is the uptime for `instance-5138`.

```
mysql> SHOW GLOBAL STATUS LIKE 'uptime';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Uptime       | 3866  |
+-----+-----+
```

By using CloudWatch, we can get the corresponding uptime information without actually logging into the instances. That way, an administrator can monitor the database but can't view or change any table data. In this case, we specify a time period spanning five minutes, and check the uptime value every minute. The increasing uptime values demonstrate that the instances weren't restarted during that period.

```
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
--namespace "AWS/RDS" --statistics Minimum --dimensions
Name=DBInstanceIdentifier,Value=instance-9404 \
--output text | sort -k 3
```

```

EngineUptime
DATAPOINTS 4648.0 2021-03-17T23:42:00+00:00 Seconds
DATAPOINTS 4708.0 2021-03-17T23:43:00+00:00 Seconds

DATAPOINTS 4555.0 2021-03-17T23:46:00+00:00 Seconds

```

Now we reboot one of the reader instances, `instance-5138`. We wait for the instance to become available again after the reboot. Now monitoring the uptime over a five-minute period shows that the uptime was reset to zero during that time. The most recent uptime value was measured five seconds after the reboot finished.

```

$ aws rds reboot-db-instance --db-instance-identifier instance-5138
{
    "DBInstanceIdentifier": "instance-5138",
    "DBInstanceState": "rebooting"
}
$ aws rds wait db-instance-available --db-instance-id instance-5138

$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
--namespace "AWS/RDS" --statistics Minimum --dimensions
Name=DBInstanceIdentifier,Value=instance-5138 \
--output text | sort -k 3

DATAPOINTS 5.0 2021-03-17T23:50:00+00:00 Seconds

```

Next, we perform a reboot for the writer instance, `instance-9404`. We compare the uptime values for the writer instance and one of the reader instances. By doing so, we can see that rebooting the writer didn't cause a reboot for the readers. In versions before Aurora MySQL 2.10, the uptime values for all the readers would be reset at the same time as the writer.

```

$ aws rds reboot-db-instance --db-instance-identifier instance-9404
{
    "DBInstanceIdentifier": "instance-9404",
    "DBInstanceState": "rebooting"
}
$ aws rds wait db-instance-available --db-instance-id instance-9404

$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
--namespace "AWS/RDS" --statistics Minimum --dimensions
Name=DBInstanceIdentifier,Value=instance-9404 \
--output text | sort -k 3
EngineUptime

DATAPOINTS 5455.0 2021-03-18T00:01:00+00:00 Seconds

```

To make sure that all the reader instances have all the same changes to configuration parameters as the writer instance, reboot all the reader instances after the writer. This example reboots all the readers and then waits until all of them are available before proceeding.

```

$ aws rds reboot-db-instance --db-instance-identifier instance-6772
{
  "DBInstanceIdentifier": "instance-6772",
  "DBInstanceState": "rebooting"
}

$ aws rds reboot-db-instance --db-instance-identifier instance-2470
{
  "DBInstanceIdentifier": "instance-2470",
  "DBInstanceState": "rebooting"
}

$ aws rds reboot-db-instance --db-instance-identifier instance-5138
{
  "DBInstanceIdentifier": "instance-5138",
  "DBInstanceState": "rebooting"
}

$ aws rds wait db-instance-available --db-instance-id instance-6772
$ aws rds wait db-instance-available --db-instance-id instance-2470
$ aws rds wait db-instance-available --db-instance-id instance-5138

```

Now we can see that the writer DB instance has the highest uptime. This instance's uptime value increased steadily throughout the monitoring period. The reader DB instances were all rebooted after the reader. We can see the point within the monitoring period when each reader was rebooted and its uptime was reset to zero.

```

$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
--start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 \

```

Applying a cluster parameter change to an Aurora MySQL version 2.10 cluster

The following example demonstrates how to apply a parameter change to all DB instances in your Aurora MySQL 2.10 cluster. With this Aurora MySQL version, you reboot the writer instance and all the reader instances independently.

The example uses the MySQL configuration parameter `lower_case_table_names` for illustration. When this parameter setting is different between the writer and reader DB instances, a query might not be able to access a table declared with an uppercase or mixed-case name. Or if two table names differ only in terms of uppercase and lowercase letters, a query might access the wrong table.

This example shows how to determine the writer and reader instances in the cluster by examining the `IsClusterWriter` attribute of each instance. The cluster is named `cluster-2393`. The cluster has a writer instance named `instance-9404`. The reader instances in the cluster are named `instance-5138` and `instance-2470`.

```

$ aws rds describe-db-clusters --db-cluster-id cluster-2393 \
--query '*[].[DBClusterIdentifier,DBClusterMembers[*]]. \
[DBInstanceIdentifier,IsClusterWriter]' \
--output text
cluster-2393
instance-5138      False
instance-2470      False
instance-9404      True

```

To demonstrate the effects of changing the `lower_case_table_names` parameter, we set up two DB cluster parameter groups. The `lower-case-table-names-0` parameter group has this parameter set to 0. The `lower-case-table-names-1` parameter group has this parameter group set to 1.

```

$ aws rds create-db-cluster-parameter-group --description 'lower-case-table-names-0' \
--db-parameter-group-family aurora-mysql5.7 \
--db-cluster-parameter-group-name lower-case-table-names-0
{
    "DBClusterParameterGroup": {
        "DBClusterParameterGroupName": "lower-case-table-names-0",
        "DBParameterGroupFamily": "aurora-mysql5.7",
        "Description": "lower-case-table-names-0"
    }
}

```

```
$ aws rds create-db-cluster-parameter-group --description 'lower-case-table-names-1' \
--db-parameter-group-family aurora-mysql5.7 \
--db-cluster-parameter-group-name lower-case-table-names-1
{
    "DBClusterParameterGroup": {
        "DBClusterParameterGroupName": "lower-case-table-names-1",
        "DBParameterGroupFamily": "aurora-mysql5.7",
        "Description": "lower-case-table-names-1"
    }
}

$ aws rds modify-db-cluster-parameter-group \
--db-cluster-parameter-group-name lower-case-table-names-0 \
--parameters ParameterName=lower_case_table_names,ParameterValue=0,ApplyMethod=pending-
reboot
{
    "DBClusterParameterGroupName": "lower-case-table-names-0"
}

$ aws rds modify-db-cluster-parameter-group \
--db-cluster-parameter-group-name lower-case-table-names-1 \
--parameters ParameterName=lower_case_table_names,ParameterValue=1,ApplyMethod=pending-
reboot
{
    "DBClusterParameterGroupName": "lower-case-table-names-1"
}
```

The default value of `lower_case_table_names` is 0. With this parameter setting, the table `foo` is distinct from the table `FOO`. This example verifies that the parameter is still at its default setting. Then the example creates three tables that differ only in uppercase and lowercase letters in their names.

```
mysql> create database lctn;
Query OK, 1 row affected (0.07 sec)

mysql> use lctn;
Database changed
mysql> select @@lower_case_table_names;
+-----+
| @@lower_case_table_names |
+-----+
|          0           |
+-----+

mysql> create table foo (s varchar(128));
mysql> insert into foo values ('Lowercase table name foo');

mysql> create table Foo (s varchar(128));
mysql> insert into Foo values ('Mixed-case table name Foo');

mysql> create table FOO (s varchar(128));
mysql> insert into FOO values ('Uppercase table name FOO');

mysql> select * from foo;
+-----+
| s           |
+-----+
| Lowercase table name foo |
+-----+

mysql> select * from Foo;
+-----+
| s           |
+-----+
```

```
| Mixed-case table name Foo |
+-----+
mysql> select * from FOO;
+-----+
| s |
+-----+
| Uppercase table name FOO |
+-----+
```

Next, we associate the DB parameter group with the cluster to set the `lower_case_table_names` parameter to 1. This change only takes effect after each DB instance is rebooted.

```
$ aws rds modify-db-cluster --db-cluster-identifier cluster-2393 \
--db-cluster-parameter-group-name lower-case-table-names-1
{
  "DBClusterIdentifier": "cluster-2393",
  "DBClusterParameterGroup": "lower-case-table-names-1",
  "Engine": "aurora-mysql",
  "EngineVersion": "5.7.mysql_aurora.2.10.0"
}
```

The first reboot we do is for the writer DB instance. Then we wait for the instance to become available again. At that point, we connect to the writer endpoint and verify that the writer instance has the changed parameter value. The `SHOW TABLES` command confirms that the database contains the three different tables. However, queries that refer to tables named `foo`, `Foo`, or `FOO` all access the table whose name is all-lowercase, `foo`.

```
# Rebooting the writer instance
$ aws rds reboot-db-instance --db-instance-identifier instance-9404
$ aws rds wait db-instance-available --db-instance-id instance-9404
```

Now, queries using the cluster endpoint show the effects of the parameter change. Whether the table name in the query is uppercase, lowercase, or mixed case, the SQL statement accesses the table whose name is all lowercase.

```
mysql> select @@lower_case_table_names;
+-----+
| @@lower_case_table_names |
+-----+
| 1 |
+-----+

mysql> use lctn;
mysql> show tables;
+-----+
| Tables_in_lctn |
+-----+
| FOO           |
| Foo          |
| foo          |
+-----+

mysql> select * from foo;
+-----+
| s |
+-----+
| Lowercase table name foo |
+-----+

mysql> select * from Foo;
+-----+
```

```

| s
+-----+
| Lowercase table name foo |
+-----+

mysql> select * from FOO;
+-----+
| s
+-----+
| Lowercase table name foo |
+-----+

```

The next example shows the same queries as the previous one. In this case, the queries use the reader endpoint and run on one of the reader DB instances. Those instances haven't been rebooted yet. Thus, they still have the original setting for the `lower_case_table_names` parameter. That means that queries can access each of the `foo`, `Foo`, and `FOO` tables.

```

mysql> select @@lower_case_table_names;
+-----+
| @@lower_case_table_names |
+-----+
| 0 |
+-----+

mysql> use lctn;

mysql> select * from foo;
+-----+
| s
+-----+
| Lowercase table name foo |
+-----+

mysql> select * from Foo;
+-----+
| s
+-----+
| Mixed-case table name Foo |
+-----+

mysql> select * from FOO;
+-----+
| s
+-----+
| Uppercase table name FOO |
+-----+

```

Next, we reboot one of the reader instances and wait for it to become available again.

```

$ aws rds reboot-db-instance --db-instance-identifier instance-2470
{
    "DBInstanceIdentifier": "instance-2470",
    "DBInstanceState": "rebooting"
}
$ aws rds wait db-instance-available --db-instance-id instance-2470

```

While connected to the instance endpoint for `instance-2470`, a query shows that the new parameter is in effect.

```

mysql> select @@lower_case_table_names;
+-----+
| @@lower_case_table_names |
+-----+

```

```
+-----+
|      1 |
+-----+
```

At this point, the two reader instances in the cluster are running with different `lower_case_table_names` settings. Thus, any connection to the reader endpoint of the cluster uses a value for this setting that's unpredictable. It's important to immediately reboot the other reader instance so that they both have consistent settings.

```
$ aws rds reboot-db-instance --db-instance-identifier instance-5138
{
  "DBInstanceIdentifier": "instance-5138",
  "DBInstanceState": "rebooting"
}
$ aws rds wait db-instance-available --db-instance-id instance-5138
```

The following example confirms that all the reader instances have the same setting for the `lower_case_table_names` parameter. The commands check the `lower_case_table_names` setting value on each reader instance. Then the same command using the reader endpoint demonstrates that each connection to the reader endpoint uses one of the reader instances, but which one isn't predictable.

```
# Check lower_case_table_names setting on each reader instance.

$ mysql -h instance-5138.a12345.us-east-1.rds.amazonaws.com \
  -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names'
+-----+
| @@aurora_server_id | @@lower_case_table_names |
+-----+
| instance-5138      |                      1 |
+-----+

$ mysql -h instance-2470.a12345.us-east-1.rds.amazonaws.com \
  -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names'
+-----+
| @@aurora_server_id | @@lower_case_table_names |
+-----+
| instance-2470      |                      1 |
+-----+

# Check lower_case_table_names setting on the reader endpoint of the cluster.

$ mysql -h cluster-2393.cluster-ro-a12345.us-east-1.rds.amazonaws.com \
  -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names'
+-----+
| @@aurora_server_id | @@lower_case_table_names |
+-----+
| instance-5138      |                      1 |
+-----+

# Run query on writer instance

$ mysql -h cluster-2393.cluster-a12345.us-east-1.rds.amazonaws.com \
  -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names'
+-----+
| @@aurora_server_id | @@lower_case_table_names |
+-----+
| instance-9404      |                      1 |
+-----+
```

With the parameter change applied everywhere, we can see the effect of setting `lower_case_table_names=1`. Whether the table is referred to as `foo`, `Foo`, or `FOO` the query converts the name to `foo` and accesses the same table in each case.

```
mysql> use lctn;
mysql> select * from foo;
+-----+
| s |
+-----+
| Lowercase table name foo |
+-----+

mysql> select * from Foo;
+-----+
| s |
+-----+
| Lowercase table name foo |
+-----+

mysql> select * from FOO;
+-----+
| s |
+-----+
| Lowercase table name foo |
+-----+
```

Deleting Aurora DB clusters and DB instances

You can delete an Aurora DB cluster when you don't need it any longer. Doing so removes the cluster volume containing all your data. Before deleting the cluster, you can save a snapshot of your data. You can restore the snapshot later to create a new cluster containing the same data.

You can also delete DB instances from a cluster, while preserving the cluster itself and the data that it contains. Doing so can help you reduce charges if the cluster isn't busy and doesn't need the computation capacity of multiple DB instances.

Topics

- [Deleting an Aurora DB cluster \(p. 467\)](#)
- [Deletion protection for Aurora clusters \(p. 471\)](#)
- [Deleting a stopped Aurora cluster \(p. 472\)](#)
- [Deleting Aurora MySQL clusters that are read replicas \(p. 472\)](#)
- [The final snapshot when deleting a cluster \(p. 472\)](#)
- [Deleting a DB instance from an Aurora DB cluster \(p. 472\)](#)

Deleting an Aurora DB cluster

Aurora doesn't provide a single-step method to delete a DB cluster. This design choice is intended to prevent you from accidentally losing data or taking your application offline. Aurora applications are typically mission-critical and require high availability. Thus, Aurora makes it easy to scale the capacity of the cluster up and down by adding and removing DB instances. However, removing the cluster itself requires you to make a separate choice.

Use the following general procedure to remove all the DB instances from a cluster and then delete the cluster itself.

1. Delete any reader instances in the cluster. Use the procedure in [Deleting a DB instance from an Aurora DB cluster \(p. 472\)](#). If the cluster has any reader instances, deleting one of the instances just reduces the computation capacity of the cluster. Deleting the reader instances first ensures that the cluster remains available throughout the procedure and doesn't perform unnecessary failover operations.
2. Delete the writer instance from the cluster. Again, use the procedure in [Deleting a DB instance from an Aurora DB cluster \(p. 472\)](#).

If you use the AWS Management Console, this is the final step. Deleting the final DB instance in a DB cluster through the console automatically deletes the DB cluster and the data in the cluster volume. At this point, Aurora prompts you to optionally create a snapshot before deleting the cluster. Aurora also requires you to confirm that you intend to delete the cluster.

3. CLI and API only: If you delete the DB instances using the AWS CLI or the RDS API, the cluster and its associated cluster volume remain even after you delete all the DB instances. To delete the cluster itself, you call the `delete-db-cluster` CLI command or `DeleteDBCluster` API operation when the cluster has zero associated DB instances. At this point, you choose whether to create a snapshot of the cluster volume. Doing so preserves the data from the cluster if you might need it later.

Topics

- [Deleting an empty Aurora cluster \(p. 468\)](#)
- [Deleting an Aurora cluster with a single DB instance \(p. 468\)](#)
- [Deleting an Aurora cluster with multiple DB instances \(p. 469\)](#)

Deleting an empty Aurora cluster

If you use the AWS Management Console, Aurora automatically deletes your cluster when you delete the last DB instance in that cluster. Thus, the procedures for deleting an empty cluster only apply when you use the AWS CLI or the RDS API.

Tip

You can keep a cluster with no DB instances to preserve your data without incurring CPU charges for the cluster. You can quickly start using the cluster again by creating one or more new DB instances for the cluster. You can perform Aurora-specific administrative operations on the cluster while it doesn't have any associated DB instances. You just can't access the data or perform any operations that require connecting to a DB instance.

To delete an empty Aurora DB cluster by using the AWS CLI, call the [delete-db-cluster](#) command.

To delete an empty Aurora DB cluster by using the Amazon RDS API, call the [DeleteDBInstance](#) operation.

Suppose that the empty cluster `deleteme-zero-instances` was only used for development and testing and doesn't contain any important data. In that case, you don't need to preserve a snapshot of the cluster volume when you delete the cluster. The following example demonstrates that a cluster doesn't contain any DB instances, and then deletes the empty cluster without creating a final snapshot.

```
$ aws rds describe-db-clusters --db-cluster-identifier deleteme-zero-instances --output text \
  --query '*[].[{"Cluster":DBClusterIdentifier,DBClusterMembers[*].["Instance":DBInstanceIdentifier,IsClusterWriter]}]
Cluster:          deleteme-zero-instances

$ aws rds delete-db-cluster --db-cluster-identifier deleteme-zero-instances --skip-final-snapshot
{
  "DBClusterIdentifier": "deleteme-zero-instances",
  "Status": "available",
  "Engine": "aurora-mysql"
}
```

Deleting an Aurora cluster with a single DB instance

If you try to delete the last DB instance in your Aurora cluster, the behavior depends on the method you use. You can delete the last DB instance using the AWS Management Console. Doing so also deletes the DB cluster. You can also delete the last DB instance through the AWS CLI or API, even if the DB cluster has deletion protection enabled. In this case, the DB cluster itself still exists and your data is preserved. You can access the data again by attaching a new DB instance to the cluster.

The following example shows how the `delete-db-cluster` command doesn't work when the cluster still has any associated DB instances. This cluster has a single writer DB instance. When we examine the DB instances in the cluster, we check the `IsClusterWriter` attribute of each one. The cluster could have zero or one writer DB instance. A value of `true` signifies a writer DB instance. A value of `false` signifies a reader DB instance. The cluster could have zero, one, or many reader DB instances. In this case, we delete the writer DB instance using the `delete-db-instance` command. As soon as the DB instance goes into deleting state, we can delete the cluster also. For this example also, suppose that the cluster doesn't contain any data worth preserving and so we don't create a snapshot of the cluster volume.

```
$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-only --skip-final-snapshot
An error occurred (InvalidDBClusterStateException) when calling the DeleteDBCluster operation:
  Cluster cannot be deleted, it still contains DB instances in non-deleting state.

$ aws rds describe-db-clusters --db-cluster-identifier deleteme-writer-only \
```

```

--query '*[].[DBClusterIdentifier,Status,DBClusterMembers[*].[DBInstanceIdentifier,IsClusterWriter]]'
[
  [
    [
      "deleteme-writer-only",
      "available",
      [
        [
          "instance-2130",
          true
        ]
      ]
    ]
  ]
]

$ aws rds delete-db-instance --db-instance-identifier instance-2130
{
  "DBInstanceIdentifier": "instance-2130",
  "DBInstanceState": "deleting",
  "Engine": "aurora-mysql"
}

$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-only --skip-final-snapshot
{
  "DBClusterIdentifier": "deleteme-writer-only",
  "Status": "available",
  "Engine": "aurora-mysql"
}

```

Deleting an Aurora cluster with multiple DB instances

If your cluster contains multiple DB instances, typically there is a single writer instance and one or more reader instances. The reader instances help with high availability, by being on standby to take over if the writer instance encounters a problem. You can also use reader instances to scale the cluster up to handle a read-intensive workload without adding overhead to the writer instance.

To delete a cluster with multiple reader DB instances, you delete the reader instances first and then the writer instance. If you use the AWS Management Console, deleting the writer instance automatically deletes the cluster afterwards. If you use the AWS CLI or RDS API, deleting the writer instance leaves the cluster and its data in place. In that case, you delete the cluster through a separate command or API operation.

- For the procedure to delete an Aurora DB instance, see [Deleting a DB instance from an Aurora DB cluster \(p. 472\)](#).
- For the procedure to delete the writer DB instance in an Aurora cluster, see [Deleting an Aurora cluster with a single DB instance \(p. 468\)](#).
- For the procedure to delete an empty Aurora cluster, see [Deleting an empty Aurora cluster \(p. 468\)](#).

This example shows how to delete a cluster containing both a writer DB instance and a single reader DB instance. The `describe-db-clusters` output shows that `instance-7384` is the writer instance and `instance-1039` is the reader instance. The example deletes the reader instance first, because deleting the writer instance while a reader instance still existed would cause a failover operation. It doesn't make sense to promote the reader instance to a writer if you plan to delete that instance also. Again, suppose that these `db.t2.small` instances are only used for development and testing, and so the delete operation skips the final snapshot.

```
$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-and-reader --skip-final-snapshot
```

```
An error occurred (InvalidDBClusterStateException) when calling the DeleteDBCluster operation:  
Cluster cannot be deleted, it still contains DB instances in non-deleting state.

$ aws rds describe-db-clusters --db-cluster-identifier deleteme-writer-and-reader --output  
text \  
--query '*[].[{"Cluster":DBClusterIdentifier,DBClusterMembers[*].  
["Instance":DBInstanceIdentifier,IsClusterWriter]}]  
Cluster:      deleteme-writer-and-reader  
Instance:     instance-1039  False  
Instance:     instance-7384  True

$ aws rds delete-db-instance --db-instance-identifier instance-1039  
{  
  "DBInstanceIdentifier": "instance-1039",  
  "DBInstanceState": "deleting",  
  "Engine": "aurora-mysql"  
}

$ aws rds delete-db-instance --db-instance-identifier instance-7384  
{  
  "DBInstanceIdentifier": "instance-7384",  
  "DBInstanceState": "deleting",  
  "Engine": "aurora-mysql"  
}

$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-and-reader --skip-  
final-snapshot  
{  
  "DBClusterIdentifier": "deleteme-writer-and-reader",  
  "Status": "available",  
  "Engine": "aurora-mysql"  
}
```

The following example shows how to delete a DB cluster containing a writer DB instance and multiple reader DB instances. It uses concise output from the `describe-db-clusters` command to get a report of the writer and reader instances. Again, we delete all reader DB instances before deleting the writer DB instance. It doesn't matter what order we delete the reader DB instances in. Suppose that this cluster with several DB instances does contain data worth preserving. Thus, the `delete-db-cluster` command in this example includes the `--no-skip-final-snapshot` and `--final-db-snapshot-identifier` parameters to specify the details of the snapshot to create.

```
$ aws rds describe-db-clusters --db-cluster-identifier deleteme-multiple-readers --output  
text \  
--query '*[].[{"Cluster":DBClusterIdentifier,DBClusterMembers[*].  
["Instance":DBInstanceIdentifier,IsClusterWriter]}]  
Cluster:      deleteme-multiple-readers  
Instance:     instance-1010  False  
Instance:     instance-5410  False  
Instance:     instance-9948  False  
Instance:     instance-8451  True

$ aws rds delete-db-instance --db-instance-identifier instance-1010  
{  
  "DBInstanceIdentifier": "instance-1010",  
  "DBInstanceState": "deleting",  
  "Engine": "aurora-mysql"  
}

$ aws rds delete-db-instance --db-instance-identifier instance-5410  
{  
  "DBInstanceIdentifier": "instance-5410",  
  "DBInstanceState": "deleting",  
  "Engine": "aurora-mysql"  
}
```

```
$ aws rds delete-db-instance --db-instance-identifier instance-9948
{
    "DBInstanceIdentifier": "instance-9948",
    "DBInstanceState": "deleting",
    "Engine": "aurora-mysql"
}

$ aws rds delete-db-instance --db-instance-identifier instance-8451
{
    "DBInstanceIdentifier": "instance-8451",
    "DBInstanceState": "deleting",
    "Engine": "aurora-mysql"
}

$ aws rds delete-db-cluster --db-cluster-identifier deleteme-multiple-readers --no-skip-
final-snapshot \
    --final-db-snapshot-identifier deleteme-multiple-readers-snapshot-11-7087
{
    "DBClusterIdentifier": "deleteme-multiple-readers",
    "Status": "available",
    "Engine": "aurora-mysql"
}
```

The following example shows how to confirm that Aurora created the requested snapshot. You can request details for the specific snapshot by specifying its identifier **deleteme-multiple-readers-snapshot-11-7087**. You can also get a report of all snapshots for the cluster that was deleted by specifying the cluster identifier **deleteme-multiple-readers**. Both of those commands return information about the same snapshot.

```
$ aws rds describe-db-cluster-snapshots --db-cluster-snapshot-identifier deleteme-multiple-
readers-snapshot-11-7087
{
    "DBClusterSnapshots": [
        {
            "AvailabilityZones": [],
            "DBClusterSnapshotIdentifier": "deleteme-multiple-readers-snapshot-11-7087",
            "DBClusterIdentifier": "deleteme-multiple-readers",
            "SnapshotCreateTime": "11T01:40:07.354000+00:00",
            "Engine": "aurora-mysql",
            ...
        }
    ]
}

$ aws rds describe-db-cluster-snapshots --db-cluster-identifier deleteme-multiple-readers
{
    "DBClusterSnapshots": [
        {
            "AvailabilityZones": [],
            "DBClusterSnapshotIdentifier": "deleteme-multiple-readers-snapshot-11-7087",
            "DBClusterIdentifier": "deleteme-multiple-readers",
            "SnapshotCreateTime": "11T01:40:07.354000+00:00",
            "Engine": "aurora-mysql",
            ...
        }
    ]
}
```

Deletion protection for Aurora clusters

You can't delete clusters that have deletion protection enabled. You can delete DB instances within the cluster, but not the cluster itself. That way, the cluster volume containing all your data is safe from accidental deletion. Aurora enforces deletion protection for a DB cluster whether you try to delete the cluster using the console, the AWS CLI, or the RDS API.

Deletion protection is enabled by default when you create a production DB cluster using the AWS Management Console. However, deletion protection is disabled by default if you create a cluster using

the AWS CLI or API. Enabling or disabling deletion protection doesn't cause an outage. To be able to delete the cluster, modify the cluster and disable deletion protection. For more information about turning deletion protection on and off, see [Modifying the DB cluster by using the console, CLI, and API \(p. 372\)](#).

Tip

Even if all the DB instances are deleted, you can access the data by creating a new DB instance in the cluster.

Deleting a stopped Aurora cluster

You can't delete a cluster if it's in the `stopped` state. In this case, start the cluster before deleting it. For more information, see [Starting an Aurora DB cluster \(p. 370\)](#).

Deleting Aurora MySQL clusters that are read replicas

For Aurora MySQL, you can't delete a DB instance in a DB cluster if both of the following conditions are true:

- The DB cluster is a read replica of another Aurora DB cluster.
- The DB instance is the only instance in the DB cluster.

To delete a DB instance in this case, first promote the DB cluster so that it's no longer a read replica. After the promotion completes, you can delete the final DB instance in the DB cluster. For more information, see [Replicating Amazon Aurora MySQL DB clusters across AWS Regions \(p. 922\)](#).

The final snapshot when deleting a cluster

Throughout this section, the examples show how you can choose whether to take a final snapshot when you delete an Aurora cluster. If you choose to take a final snapshot but the name you specify matches an existing snapshot, the operation stops with an error. In this case, examine the snapshot details to confirm if it represents your current detail or if it is an older snapshot. If the existing snapshot doesn't have the latest data that you want to preserve, rename the snapshot and try again, or specify a different name for the `final_snapshot` parameter.

Deleting a DB instance from an Aurora DB cluster

You can delete a DB instance from an Aurora DB cluster as part of the process of deleting the entire cluster. If your cluster contains a certain number of DB instances, then deleting the cluster requires deleting each of those DB instances. You can also delete one or more reader instances from a cluster while leaving the cluster running. You might do so to reduce compute capacity and associated charges if your cluster isn't busy.

To delete a DB instance, you specify the name of the instance.

You can delete a DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

For Aurora DB clusters, deleting a DB instance doesn't necessarily delete the entire cluster. You can delete a DB instance in an Aurora cluster to reduce compute capacity and associated charges when the cluster isn't busy. For information about the special circumstances for Aurora clusters that have one DB instance or zero DB instances, see [Deleting an Aurora cluster with a single DB instance \(p. 468\)](#) and [Deleting an empty Aurora cluster \(p. 468\)](#).

Note

You can't delete a DB cluster when deletion protection is enabled for it. For more information, see [Deletion protection for Aurora clusters \(p. 471\)](#).

You can disable deletion protection by modifying the DB cluster. For more information, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

Console

To delete a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to delete.
3. For **Actions**, choose **Delete**.
4. Enter **delete me** in the box.
5. Choose **Delete**.

AWS CLI

To delete a DB instance by using the AWS CLI, call the `delete-db-instance` command and specify the `--db-instance-identifier` value.

Example

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
--db-instance-identifier mydbinstance
```

For Windows:

```
aws rds delete-db-instance ^
--db-instance-identifier mydbinstance
```

RDS API

To delete a DB instance by using the Amazon RDS API, call the `DeleteDBInstance` operation and specify the `DBInstanceIdentifier` parameter.

Note

When the status for a DB instance is `deleting`, its CA certificate value doesn't appear in the RDS console or in output for AWS CLI commands or RDS API operations. For more information about CA certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1714\)](#).

Tagging Amazon RDS resources

You can use Amazon RDS tags to add metadata to your Amazon RDS resources. You can use the tags to add your own notations about database instances, snapshots, Aurora clusters, and so on. Doing so can help you to document your Amazon RDS resources. You can also use the tags with automated maintenance procedures.

In particular, you can use these tags with IAM policies to manage access to Amazon RDS resources and to control what actions can be applied to the Amazon RDS resources. You can also use these tags to track costs by grouping expenses for similarly tagged resources.

You can tag the following Amazon RDS resources:

- DB instances
- DB clusters
- Read replicas
- DB snapshots
- DB cluster snapshots
- Reserved DB instances
- Event subscriptions
- DB option groups
- DB parameter groups
- DB cluster parameter groups
- DB security groups
- DB subnet groups
- RDS Proxies
- RDS Proxy endpoints

Note

Currently, you can't tag RDS Proxies and RDS Proxy endpoints by using the AWS Management Console.

Overview of Amazon RDS resource tags

An Amazon RDS tag is a name-value pair that you define and associate with an Amazon RDS resource. The name is referred to as the key. Supplying a value for the key is optional. You can use tags to assign arbitrary information to an Amazon RDS resource. You can use a tag key, for example, to define a category, and the tag value might be an item in that category. For example, you might define a tag key

of "project" and a tag value of "Salix", indicating that the Amazon RDS resource is assigned to the Salix project. You can also use tags to designate Amazon RDS resources as being used for test or production by using a key such as `environment=test` or `environment=production`. We recommend that you use a consistent set of tag keys to make it easier to track metadata associated with Amazon RDS resources.

In addition, you can use conditions in your IAM policies to control access to AWS resources based on the tags on that resource. You can do this by using the global `aws:ResourceTag/tag-key` condition key. For more information, see [Controlling access to AWS resources](#) in the *AWS Identity and Access Management User Guide*.

Each Amazon RDS resource has a tag set, which contains all the tags that are assigned to that Amazon RDS resource. A tag set can contain as many as 50 tags, or it can be empty. If you add a tag to an Amazon RDS resource that has the same key as an existing tag on resource, the new value overwrites the old value.

AWS does not apply any semantic meaning to your tags; tags are interpreted strictly as character strings. Amazon RDS can set tags on a DB instance or other Amazon RDS resources, depending on the settings that you use when you create the resource. For example, Amazon RDS might add a tag indicating that a DB instance is for production or for testing.

- The tag key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with `aws:` or `rds:`. The string can contain only the set of Unicode letters, digits, white-space, `'`, `!`, `:`, `/`, `=`, `+`, `-`, `@` (Java regex: `^([\u0000-\uFFFF]\u0000-\uFFFF]*$)`).
- The tag value is an optional string value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with `aws:`. The string can contain only the set of Unicode letters, digits, white-space, `'`, `!`, `:`, `/`, `=`, `+`, `-`, `@` (Java regex: `^([\u0000-\uFFFF]\u0000-\uFFFF]*$)`).

Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of `project=Trinity` and `cost-center=Trinity`.

You can use the AWS Management Console, the command line interface, or the Amazon RDS API to add, list, and delete tags on Amazon RDS resources. When using the command line interface or the Amazon RDS API, you must provide the Amazon Resource Name (ARN) for the Amazon RDS resource you want to work with. For more information about constructing an ARN, see [Constructing an ARN for Amazon RDS \(p. 482\)](#).

Tags are cached for authorization purposes. Because of this, additions and updates to tags on Amazon RDS resources can take several minutes before they are available.

Using tags for access control with IAM

You can use tags with IAM policies to manage access to Amazon RDS resources and to control what actions can be applied to the Amazon RDS resources.

For information on managing access to tagged resources with IAM policies, see [Identity and access management in Amazon Aurora \(p. 1724\)](#).

Using tags to produce detailed billing reports

You can also use tags to track costs by grouping expenses for similarly tagged resources.

Use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. Then, to see the cost of combined resources, organize your

billing information according to resources with the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see [Using Cost Allocation Tags](#) in the *AWS Billing and Cost Management User Guide*.

Note

You can add a tag to a snapshot, however, your bill will not reflect this grouping.

Adding, listing, and removing tags

The following procedures show how to perform typical tagging operations on resources related to DB instances and Aurora DB clusters.

Console

The process to tag an Amazon RDS resource is similar for all resources. The following procedure shows how to tag an Amazon RDS DB instance.

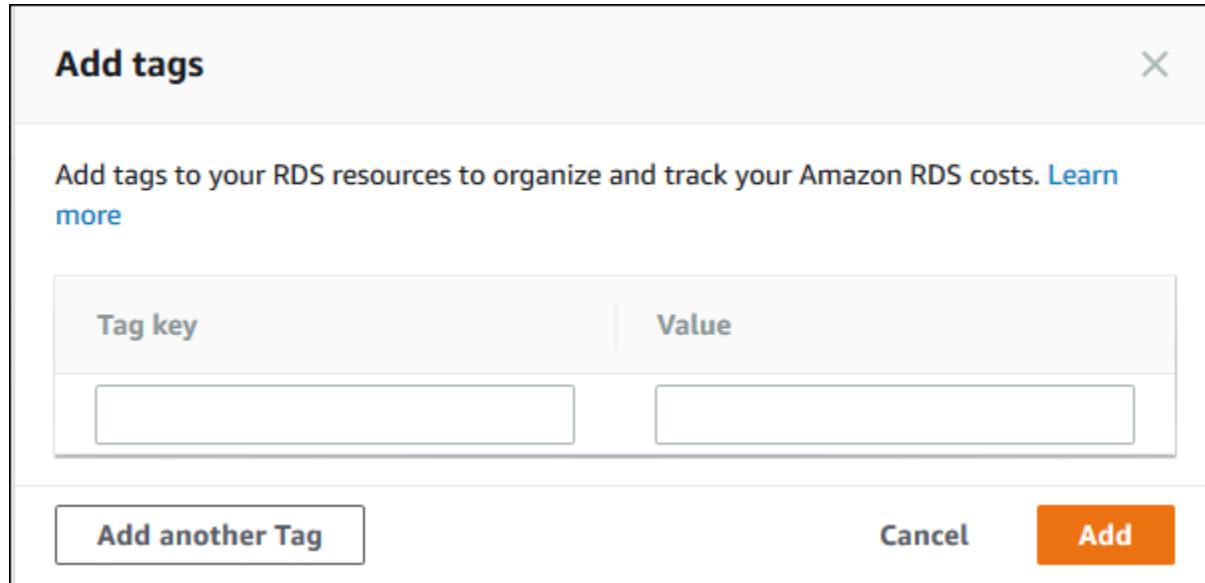

To add a tag to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

Note

To filter the list of DB instances in the **Databases** pane, enter a text string for **Filter databases**. Only DB instances that contain the string appear.

3. Choose the name of the DB instance that you want to tag to show its details.
4. In the details section, scroll down to the **Tags** section.
5. Choose **Add**. The **Add tags** window appears.

6. Enter a value for **Tag key** and **Value**.
7. To add another tag, you can choose **Add another Tag** and enter a value for its **Tag key** and **Value**.
Repeat this step as many times as necessary.
8. Choose **Add**.

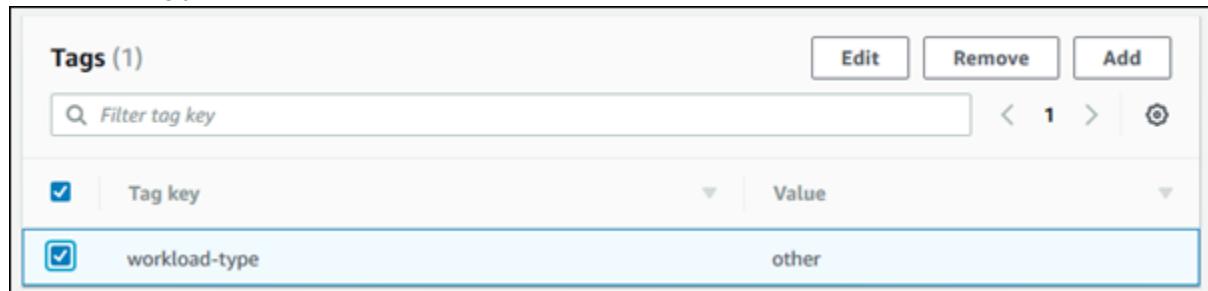

To delete a tag from a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

Note

To filter the list of DB instances in the **Databases** pane, enter a text string in the **Filter databases** box. Only DB instances that contain the string appear.

3. Choose the name of the DB instance to show its details.
4. In the details section, scroll down to the **Tags** section.
5. Choose the tag you want to delete.

6. Choose **Delete**, and then choose **Delete** in the **Delete tags** window.

AWS CLI

You can add, list, or remove tags for a DB instance using the AWS CLI.

- To add one or more tags to an Amazon RDS resource, use the AWS CLI command [add-tags-to-resource](#).
- To list the tags on an Amazon RDS resource, use the AWS CLI command [list-tags-for-resource](#).
- To remove one or more tags from an Amazon RDS resource, use the AWS CLI command [remove-tags-from-resource](#).

To learn more about how to construct the required ARN, see [Constructing an ARN for Amazon RDS \(p. 482\)](#).

RDS API

You can add, list, or remove tags for a DB instance using the Amazon RDS API.

- To add a tag to an Amazon RDS resource, use the [AddTagsToResource](#) operation.
- To list tags that are assigned to an Amazon RDS resource, use the [ListTagsForResource](#).
- To remove tags from an Amazon RDS resource, use the [RemoveTagsFromResource](#) operation.

To learn more about how to construct the required ARN, see [Constructing an ARN for Amazon RDS \(p. 482\)](#).

When working with XML using the Amazon RDS API, tags use the following schema:

```
<Tagging>
  <TagSet>
    <Tag>
      <Key>Project</Key>
```

```

        <Value>Trinity</Value>
    </Tag>
    <Tag>
        <Key>User</Key>
        <Value>Jones</Value>
    </Tag>
</TagSet>
</Tagging>

```

The following table provides a list of the allowed XML tags and their characteristics. Values for Key and Value are case-dependent. For example, project=Trinity and PROJECT=Trinity are two distinct tags.

Tagging element	Description
TagSet	A tag set is a container for all tags assigned to an Amazon RDS resource. There can be only one tag set per resource. You work with a TagSet only through the Amazon RDS API.
Tag	A tag is a user-defined key-value pair. There can be from 1 to 50 tags in a tag set.
Key	A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with <code>aws:</code> or <code>rds:</code> . The string can only contain only the set of Unicode letters, digits, white-space, '_', '.', '/', '=', '+', '-' (Java regex: " <code>^([\u00p{L}\u00p{Z}\u00p{N}_:/=-]+\u00p{-})*\$</code> "). Keys must be unique to a tag set. For example, you cannot have a key-pair in a tag set with the key the same but with different values, such as <code>project/Trinity</code> and <code>project/Xanadu</code> .
Value	A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with <code>aws:</code> or <code>rds:</code> . The string can only contain only the set of Unicode letters, digits, white-space, '_', '.', '/', '=', '+', '-' (Java regex: " <code>^([\u00p{L}\u00p{Z}\u00p{N}_:/=-]+\u00p{-})*\$</code> "). Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of <code>project/Trinity</code> and <code>cost-center/Trinity</code> .

Using the AWS Tag Editor

You can browse and edit the tags on your RDS resources in the AWS Management Console by using the AWS Tag editor. For more information, see [Tag Editor](#) in the *AWS Resource Groups User Guide*.

Copying tags to DB cluster snapshots

When you create or restore a DB cluster, you can specify that the tags from the DB cluster are copied to snapshots of the DB cluster. Copying tags ensures that the metadata for the DB snapshots matches that of the source DB cluster and any access policies for the DB snapshot also match those of the source DB cluster. Tags are not copied by default.

You can specify that tags are copied to DB snapshots for the following actions:

- Creating a DB cluster.
- Restoring a DB cluster.
- Creating a read replica.

- Copying a DB cluster snapshot.

Note

If you include a value for the `--tag-key` parameter of the `create-db-cluster-snapshot` AWS CLI command (or supply at least one tag to the `CreateDBClusterSnapshot` API operation) then RDS doesn't copy tags from the source DB cluster to the new DB snapshot. This functionality applies even if the source DB cluster has the `--copy-tags-to-snapshot` (`CopyTagsToSnapshot`) option enabled. If you take this approach, you can create a copy of a DB cluster from a DB cluster snapshot and avoid adding tags that don't apply to the new DB cluster. Once you have created your DB cluster snapshot using the AWS CLI `create-db-cluster-snapshot` command (or the `CreateDBSnapshot` Amazon RDS API operation) you can then add tags as described later in this topic.

Tutorial: Use tags to specify which Aurora DB clusters to stop

Suppose that you're creating a number of Aurora DB clusters in a development or test environment. You need to keep all of these clusters for several days. Some of the clusters run tests overnight. Other clusters can be stopped overnight and started again the next day. The following example shows how to assign a tag to those clusters that are suitable to stop overnight. Then the example shows how a script can detect which clusters have that tag and then stop those clusters. In this example, the value portion of the key-value pair doesn't matter. The presence of the `stopable` tag signifies that the cluster has this user-defined property.

To specify which Aurora DB clusters to stop

1. Determine the ARN of a cluster that you want to designate as stoppable.

The commands and APIs for tagging work with ARNs. That way, they can work seamlessly across AWS Regions, AWS accounts, and different types of resources that might have identical short names. You can specify the ARN instead of the cluster ID in CLI commands that operate on clusters. Substitute the name of your own cluster for `dev-test-cluster`. In subsequent commands that use ARN parameters, substitute the ARN of your own cluster. The ARN includes your own AWS account ID and the name of the AWS Region where your cluster is located.

```
$ aws rds describe-db-clusters --db-cluster-identifier dev-test-cluster \
--query "[].{DBClusterArn:DBClusterArn}" --output text
arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster
```

2. Add the tag `stopable` to this cluster.

The name for this tag is chosen by you. Using a tag like this is an alternative to devising a naming convention that encodes all the relevant information in the name of the cluster, DB instance, and so on. Because this example treats the tag as an attribute that is either present or absent, it omits the `Value=` part of the `--tags` parameter.

```
$ aws rds add-tags-to-resource \
--resource-name arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster \
--tags Key=stopable
```

3. Confirm that the tag is present in the cluster.

These commands retrieve the tag information for the cluster in JSON format and in plain tab-separated text.

```
$ aws rds list-tags-for-resource \
```

```
--resource-name arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster
{
    "TagList": [
        {
            "Key": "stoppable",
            "Value": ""
        }
    ]
}
$ aws rds list-tags-for-resource \
--resource-name arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster --output
text
TAGLIST stoppable
```

- To stop all the clusters that are designated as stoppable, prepare a list of all your clusters. Loop through the list and check if each cluster is tagged with the relevant attribute.

This Linux example uses shell scripting to save the list of cluster ARNs to a temporary file and then perform CLI commands for each cluster.

```
$ aws rds describe-db-clusters --query "*[].[DBClusterArn]" --output text >/tmp/
cluster_arns.lst
$ for arn in $(cat /tmp/cluster_arns.lst)
do
    match=$(aws rds list-tags-for-resource --resource-name $arn --output text | grep
'TAGLIST\|tstopable')
    if [[ ! -z "$match" ]]
    then
        echo "Cluster $arn is tagged as stoppable. Stopping it now."
    # Note that you can specify the full ARN value as the parameter instead of the short ID
    'dev-test-cluster'.
        aws rds stop-db-cluster --db-cluster-identifier $arn
    fi
done

Cluster arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster is tagged as
stoppable. Stopping it now.
{
    "DBCluster": {
        "AllocatedStorage": 1,
        "AvailabilityZones": [
            "us-east-1e",
            "us-east-1c",
            "us-east-1d"
        ],
        "BackupRetentionPeriod": 1,
        "DBClusterIdentifier": "dev-test-cluster",
        ...
    }
}
```

You can run a script like this at the end of each day to make sure that nonessential clusters are stopped. You might also schedule a job using a utility such as cron to perform such a check each night, in case some clusters were left running by mistake. In that case, you might fine-tune the command that prepares the list of clusters to check. The following command produces a list of your clusters, but only the ones in available state. The script can ignore clusters that are already stopped, because they will have different status values such as stopped or stopping.

```
$ aws rds describe-db-clusters \
--query '*[].[DBClusterArn:DBClusterArn,Status:Status]|?Status == `available`|[]'.
{DBClusterArn:DBClusterArn} \
--output text
arn:aws:rds:us-east-1:123456789:cluster:cluster-2447
```

```
arn:aws:rds:us-east-1:123456789:cluster:cluster-3395
arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster
arn:aws:rds:us-east-1:123456789:cluster:pg2-cluster
```

Tip

After you're familiar with the general procedure of assigning tags and finding clusters that have those tags, you can use the same technique to reduce costs in other ways. For example, in this scenario with Aurora DB clusters used for development and testing, you might designate some clusters to be deleted at the end of each day, or to have only their reader DB instances deleted, or to have their DB instances changed to a small DB instance classes during times of expected low usage.

Working with Amazon Resource Names (ARNs) in Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). For certain Amazon RDS operations, you must uniquely identify an Amazon RDS resource by specifying its ARN. For example, when you create an RDS DB instance read replica, you must supply the ARN for the source DB instance.

Constructing an ARN for Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). You can construct an ARN for an Amazon RDS resource using the following syntax.

`arn:aws:rds:<region>:<account number>:<resourcetype>:<name>`

Region Name	Region	Endpoint	Protocol	
US East (Ohio)	us-east-2	rds.us-east-2.amazonaws.com rds-fips.us-east-2.amazonaws.com rds-fips.us-east-2.amazonaws.com	HTTPS HTTPS HTTPS	
US East (N. Virginia)	us-east-1	rds.us-east-1.amazonaws.com rds-fips.us-east-1.amazonaws.com rds-fips.us-east-1.amazonaws.com	HTTPS HTTPS HTTPS	
US West (N. California)	us-west-1	rds.us-west-1.amazonaws.com rds-fips.us-west-1.amazonaws.com rds-fips.us-west-1.amazonaws.com	HTTPS HTTPS HTTPS	
US West (Oregon)	us-west-2	rds.us-west-2.amazonaws.com rds-fips.us-west-2.amazonaws.com rds-fips.us-west-2.amazonaws.com	HTTPS HTTPS HTTPS	
Africa (Cape Town)	af-south-1	rds.af-south-1.amazonaws.com	HTTPS	
Asia Pacific (Hong Kong)	ap-east-1	rds.ap-east-1.amazonaws.com	HTTPS	
Asia Pacific (Jakarta)	ap-southeast-3	rds.ap-southeast-3.amazonaws.com	HTTPS	

Region Name	Region	Endpoint	Protocol	
Asia Pacific (Mumbai)	ap-south-1	rds.ap-south-1.amazonaws.com	HTTPS	
Asia Pacific (Osaka)	ap-northeast-3	rds.ap-northeast-3.amazonaws.com	HTTPS	
Asia Pacific (Seoul)	ap-northeast-2	rds.ap-northeast-2.amazonaws.com	HTTPS	
Asia Pacific (Singapore)	ap-southeast-1	rds.ap-southeast-1.amazonaws.com	HTTPS	
Asia Pacific (Sydney)	ap-southeast-2	rds.ap-southeast-2.amazonaws.com	HTTPS	
Asia Pacific (Tokyo)	ap-northeast-1	rds.ap-northeast-1.amazonaws.com	HTTPS	
Canada (Central)	ca-central-1	rds.ca-central-1.amazonaws.com	HTTPS	
		rds-fips.ca-central-1.amazonaws.com	HTTPS	
		rds-fips.ca-central-1.amazonaws.com	HTTPS	
Europe (Frankfurt)	eu-central-1	rds.eu-central-1.amazonaws.com	HTTPS	
Europe (Ireland)	eu-west-1	rds.eu-west-1.amazonaws.com	HTTPS	
Europe (London)	eu-west-2	rds.eu-west-2.amazonaws.com	HTTPS	
Europe (Milan)	eu-south-1	rds.eu-south-1.amazonaws.com	HTTPS	
Europe (Paris)	eu-west-3	rds.eu-west-3.amazonaws.com	HTTPS	
Europe (Stockholm)	eu-north-1	rds.eu-north-1.amazonaws.com	HTTPS	
Middle East (Bahrain)	me-south-1	rds.me-south-1.amazonaws.com	HTTPS	
South America (São Paulo)	sa-east-1	rds.sa-east-1.amazonaws.com	HTTPS	

Region Name	Region	Endpoint	Protocol	
AWS GovCloud (US-East)	us-gov-east-1	rds.us-gov-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-West)	us-gov-west-1	rds.us-gov-west-1.amazonaws.com	HTTPS	

The following table shows the format that you should use when constructing an ARN for a particular Amazon RDS resource type.

Resource type	ARN format
DB instance	<p>arn:aws:rds:<region>:<account>:db:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:db:my-mysql-instance-1</pre>
DB cluster	<p>arn:aws:rds:<region>:<account>:cluster:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:cluster:my-aurora-cluster-1</pre>
Event subscription	<p>arn:aws:rds:<region>:<account>:es:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:es:my-subscription</pre>
DB parameter group	<p>arn:aws:rds:<region>:<account>:pg:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:pg:my-param-enable-logs</pre>
DB cluster parameter group	<p>arn:aws:rds:<region>:<account>:cluster-pg:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:cluster-pg:my-cluster-param-timezone</pre>
Reserved DB instance	<p>arn:aws:rds:<region>:<account>:ri:<name></p> <p>For example:</p>

Resource type	ARN format
	<code>arn:aws:rds:us-east-2:123456789012:ri:my-reserved-postgresql</code>
DB security group	<p><code>arn:aws:rds:<region>:<account>:secgrp:<name></code></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:secgrp:my-public</pre>
Automated DB snapshot	<p><code>arn:aws:rds:<region>:<account>:snapshot:rds:<name></code></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:snapshot:rds:my-mysql-db-2019-07-22-07-23</pre>
Automated DB cluster snapshot	<p><code>arn:aws:rds:<region>:<account>:cluster-snapshot:rds:<name></code></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:cluster-snapshot:rds:my-aurora-cluster-2019-07-22-16-16</pre>
Manual DB snapshot	<p><code>arn:aws:rds:<region>:<account>:snapshot:<name></code></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:snapshot:my-mysql-db-snap</pre>
Manual DB cluster snapshot	<p><code>arn:aws:rds:<region>:<account>:cluster-snapshot:<name></code></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:cluster-snapshot:my-aurora-cluster-snap</pre>
DB subnet group	<p><code>arn:aws:rds:<region>:<account>:subgrp:<name></code></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:subgrp:my-subnet-10</pre>

Getting an existing ARN

You can get the ARN of an RDS resource by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or RDS API.

Console

To get an ARN from the AWS Management Console, navigate to the resource you want an ARN for, and view the details for that resource. For example, you can get the ARN for a DB instance from the **Configuration** tab of the DB instance details, as shown following.

The screenshot shows the AWS Management Console interface for a DB instance named "oracle-instance1". The top navigation bar has tabs: Connectivity, Monitoring, Logs & events, and Configuration. The Configuration tab is highlighted with a red oval. Below the tabs, the page title is "Instance" and the section title is "Configuration". The configuration details listed are:

- DB instance id: oracle-instance1
- Engine version: 12.1.0.2.v14
- Storage type: General Purpose (SSD)
- IOPS: -
- Storage: 20 GiB
- DB name: ORCL
- License model: Bring Your Own License
- Character set: AL32UTF8
- Option groups: default:oracle-ee-12-1
- ARN: arn:aws:rds:us-west-2:XXXXXXXXXXXX:db:oracle-instance1
- Resource id: (redacted)

AWS CLI

To get an ARN from the AWS CLI for a particular RDS resource, you use the `describe` command for that resource. The following table shows each AWS CLI command, and the ARN property used with the command to get an ARN.

AWS CLI command	ARN property
describe-event-subscriptions	EventSubscriptionArn
describe-certificates	CertificateArn
describe-db-parameter-groups	DBParameterGroupArn
describe-db-cluster-parameter-groups	DBClusterParameterGroupArn
describe-db-instances	DBInstanceArn
describe-db-security-groups	DBSecurityGroupArn
describe-db-snapshots	DBSnapshotArn
describe-events	SourceArn
describe-reserved-db-instances	ReservedDBInstanceArn
describe-db-subnet-groups	DBSubnetGroupArn
describe-db-clusters	DBClusterArn
describe-db-cluster-snapshots	DBClusterSnapshotArn

For example, the following AWS CLI command gets the ARN for a DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
--db-instance-identifier DBInstanceIdentifier \
--region us-west-2 \
--query "[].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

For Windows:

```
aws rds describe-db-instances ^
--db-instance-identifier DBInstanceIdentifier ^
--region us-west-2 ^
--query "[].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

The output of that command is like the following:

```
[  
  {  
    "DBInstanceArn": "arn:aws:rds:us-west-2:account_id:db:instance_id",  
    "DBInstanceIdentifier": "instance_id"  
  }  
]
```

RDS API

To get an ARN for a particular RDS resource, you can call the following RDS API operations and use the ARN properties shown following.

RDS API operation	ARN property
DescribeEventSubscriptions	EventSubscriptionArn
DescribeCertificates	CertificateArn
DescribeDBParameterGroups	DBParameterGroupArn
DescribeDBClusterParameterGroups	DBClusterParameterGroupArn
DescribeDBInstances	DBInstanceArn
DescribeDBSecurityGroups	DBSecurityGroupArn
DescribeDBSnapshots	DBSnapshotArn
DescribeEvents	SourceArn
DescribeReservedDBInstances	ReservedDBInstanceArn
DescribeDBSubnetGroups	DBSubnetGroupArn
DescribeDBClusters	DBClusterArn
DescribeDBClusterSnapshots	DBClusterSnapshotArn

Amazon Aurora updates

Amazon Aurora releases updates regularly. Updates are applied to Amazon Aurora DB clusters during system maintenance windows. The timing when updates are applied depends on the region and maintenance window setting for the DB cluster, and also the type of update. Updates require a database restart, so you typically experience 20 to 30 seconds of downtime. After this downtime, you can resume using your DB cluster or clusters. You can view or change your maintenance window settings from the [AWS Management Console](#).

Note

The time required to reboot your DB instance depends on the crash recovery process, database activity at the time of reboot, and the behavior of your specific DB engine. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

Following, you can find information on general updates to Amazon Aurora. Some of the updates applied to Amazon Aurora are specific to a database engine supported by Aurora. For more information about database engine updates for Aurora, see the following table.

Database engine	Updates
Amazon Aurora MySQL	See Database engine updates for Amazon Aurora MySQL (p. 1082)
Amazon Aurora PostgreSQL	See Amazon Aurora PostgreSQL updates (p. 1597)

Identifying your Amazon Aurora version

Amazon Aurora includes certain features that are general to Aurora and available to all Aurora DB clusters. Aurora includes other features that are specific to a particular database engine that Aurora supports. These features are available only to those Aurora DB clusters that use that database engine, such as Aurora PostgreSQL.

An Aurora DB instance provides two version numbers, the Aurora version number and the Aurora database engine version number. Aurora version numbers use the following format.

```
<major version>.<minor version>.<patch version>
```

To get the Aurora version number from an Aurora DB instance using a particular database engine, use one of the following queries.

Database engine	Queries
Amazon Aurora MySQL	<pre>SELECT AURORA_VERSION();</pre>
Amazon Aurora PostgreSQL	<pre>SHOW @@aurora_version;</pre>

Backing up and restoring an Amazon Aurora DB cluster

This section shows how to back up and restore Amazon Aurora DB clusters.

Overview of backing up and restoring an Aurora DB cluster

In the following sections, you can find information about Aurora backups and how to restore your Aurora DB cluster using the AWS Management Console.

Tip

The Aurora high availability features and automatic backup capabilities help to keep your data safe without requiring extensive setup from you. Before you implement a backup strategy, learn about the ways that Aurora maintains multiple copies of your data and helps you to access them across multiple DB instances and AWS Regions. For details, see [High availability for Amazon Aurora \(p. 68\)](#).

Backups

Aurora backs up your cluster volume automatically and retains restore data for the length of the *backup retention period*. Aurora backups are continuous and incremental so you can quickly restore to any point within the backup retention period. No performance impact or interruption of database service occurs as backup data is being written. You can specify a backup retention period, from 1 to 35 days, when you create or modify a DB cluster. Aurora backups are stored in Amazon S3.

If you want to retain a backup beyond the backup retention period, you can also take a snapshot of the data in your cluster volume. Because Aurora retains incremental restore data for the entire backup retention period, you only need to create a snapshot for data that you want to retain beyond the backup retention period. You can create a new DB cluster from the snapshot.

Note

- For Amazon Aurora DB clusters, the default backup retention period is one day regardless of how the DB cluster is created.
- You can't disable automated backups on Aurora. The backup retention period for Aurora is managed by the DB cluster.

Your costs for backup storage depend upon the amount of Aurora backup and snapshot data you keep and how long you keep it. For information about the storage associated with Aurora backups and snapshots, see [Understanding Aurora backup storage usage \(p. 494\)](#). For pricing information about Aurora backup storage, see [Amazon RDS for Aurora pricing](#). After the Aurora cluster associated with a snapshot is deleted, storing that snapshot incurs the standard backup storage charges for Aurora.

Note

You can also use AWS Backup to manage backups of Amazon Aurora DB clusters. Backups managed by AWS Backup are considered manual DB cluster snapshots, but don't count toward the DB cluster snapshot quota for Aurora. Backups that were created with AWS Backup have names ending in `awsbackup:AWS-Backup-job-number`. For information about AWS Backup, see the [AWS Backup Developer Guide](#).

Backup window

Automated backups occur daily during the preferred backup window. If the backup requires more time than allotted to the backup window, the backup continues after the window ends, until it finishes. The backup window can't overlap with the weekly maintenance window for the DB cluster.

Aurora backups are continuous and incremental, but the backup window is used to create a daily system backup that is preserved within the backup retention period. You can copy it to preserve it outside of the retention period.

Note

When you create a DB cluster using the AWS Management Console, you can't specify a backup window. However, you can specify a backup window when you create a DB cluster using the AWS CLI or RDS API.

If you don't specify a preferred backup window when you create the DB cluster, Aurora assigns a default 30-minute backup window. This window is selected at random from an 8-hour block of time for each AWS Region. The following table lists the time blocks for each AWS Region from which the default backup windows are assigned.

Region Name	Region	Time Block
US East (Ohio)	us-east-2	03:00–11:00 UTC
US East (N. Virginia)	us-east-1	03:00–11:00 UTC
US West (N. California)	us-west-1	06:00–14:00 UTC
US West (Oregon)	us-west-2	06:00–14:00 UTC
Africa (Cape Town)	af-south-1	03:00–11:00 UTC
Asia Pacific (Hong Kong)	ap-east-1	06:00–14:00 UTC
Asia Pacific (Jakarta)	ap-southeast-3	08:00–16:00 UTC
Asia Pacific (Mumbai)	ap-south-1	16:30–00:30 UTC
Asia Pacific (Osaka)	ap-northeast-3	00:00–08:00 UTC
Asia Pacific (Seoul)	ap-northeast-2	13:00–21:00 UTC
Asia Pacific (Singapore)	ap-southeast-1	14:00–22:00 UTC
Asia Pacific (Sydney)	ap-southeast-2	12:00–20:00 UTC
Asia Pacific (Tokyo)	ap-northeast-1	13:00–21:00 UTC
Canada (Central)	ca-central-1	03:00–11:00 UTC
China (Beijing)	cn-north-1	06:00–14:00 UTC
China (Ningxia)	cn-northwest-1	06:00–14:00 UTC
Europe (Frankfurt)	eu-central-1	20:00–04:00 UTC
Europe (Ireland)	eu-west-1	22:00–06:00 UTC
Europe (London)	eu-west-2	22:00–06:00 UTC
Europe (Paris)	eu-west-3	07:29–14:29 UTC
Europe (Milan)	eu-south-1	02:00–10:00 UTC
Europe (Stockholm)	eu-north-1	23:00–07:00 UTC
Middle East (Bahrain)	me-south-1	06:00–14:00 UTC
South America (São Paulo)	sa-east-1	23:00–07:00 UTC

Region Name	Region	Time Block
AWS GovCloud (US-East)	us-gov-east-1	17:00–01:00 UTC
AWS GovCloud (US-West)	us-gov-west-1	06:00–14:00 UTC

Restoring data

You can recover your data by creating a new Aurora DB cluster from the backup data that Aurora retains, or from a DB cluster snapshot that you have saved. You can quickly restore a new copy of a DB cluster created from backup data to any point in time during your backup retention period. The continuous and incremental nature of Aurora backups during the backup retention period means you don't need to take frequent snapshots of your data to improve restore times.

To determine the latest or earliest restorable time for a DB cluster, look for the `Latest restore time` or `Earliest restorable time` values on the RDS console. For information about viewing these values, see [Viewing an Amazon Aurora DB cluster \(p. 547\)](#). The latest restorable time for a DB cluster is the most recent point at which you can restore your DB cluster, typically within 5 minutes of the current time. The earliest restorable time specifies how far back within the backup retention period that you can restore your cluster volume.

You can determine when the restore of a DB cluster is complete by checking the `Latest Restorable Time` and `Earliest Restorable Time` values. The `Latest Restorable Time` and `Earliest Restorable Time` values return `NULL` until the restore operation is complete. You can't request a backup or restore operation if `Latest Restorable Time` or `Earliest Restorable Time` returns `NULL`.

For information about restoring a DB cluster to a specified time, see [Restoring a DB cluster to a specified time \(p. 537\)](#).

Database cloning for Aurora

You can also use database cloning to clone the databases of your Aurora DB cluster to a new DB cluster, instead of restoring a DB cluster snapshot. The clone databases use only minimal additional space when first created. Data is copied only as data changes, either on the source databases or the clone databases. You can make multiple clones from the same DB cluster, or create additional clones even from other clones. For more information, see [Cloning a volume for an Aurora DB cluster \(p. 402\)](#).

Backtrack

Aurora MySQL now supports "rewinding" a DB cluster to a specific time, without restoring data from a backup. For more information, see [Backtracking an Aurora DB cluster \(p. 816\)](#).

Understanding Aurora backup storage usage

Aurora stores continuous backups (within the backup retention period) and snapshots in Aurora backup storage. To control your backup storage usage, you can reduce the backup retention interval, remove old manual snapshots when they are no longer needed, or both. For general information about Aurora backups, see [Backups \(p. 491\)](#). For pricing information about Aurora backup storage, see the [Amazon Aurora pricing](#) webpage.

To control your costs, you can monitor the amount of storage consumed by continuous backups and manual snapshots that persist beyond the retention period. Then you can reduce the backup retention interval and remove manual snapshots when they are no longer needed.

You can use the Amazon CloudWatch metrics `TotalBackupStorageBilled`, `SnapshotStorageUsed`, and `BackupRetentionPeriodStorageUsed` to review and monitor the amount of storage used by your Aurora backups, as follows:

- `BackupRetentionPeriodStorageUsed` represents the amount of backup storage used, in bytes, for storing continuous backups at the current time. This value depends on the size of the cluster volume and the amount of changes you make during the retention period. However, for billing purposes it doesn't exceed the cumulative cluster volume size during the retention period. For example, if your cluster's `VolumeBytesUsed` size is 107,374,182,400 bytes (100 GiB), and your retention period is two days, the maximum value for `BackupRetentionPeriodStorageUsed` is 214,748,364,800 bytes (100 GiB + 100 GiB).
- `SnapshotStorageUsed` represents the amount of backup storage used, in bytes, for storing manual snapshots beyond the backup retention period. Manual snapshots don't count against your snapshot backup storage while their creation timestamp is within the retention period. All automatic snapshots also don't count against your snapshot backup storage. The size of each snapshot is the size of the cluster volume at the time you take the snapshot. The `SnapshotStorageUsed` value depends on the number of snapshots you keep and the size of each snapshot. For example, suppose you have one manual snapshot outside the retention period, and the cluster's `VolumeBytesUsed` size was 100 GiB when that snapshot was taken. The amount of `SnapshotStorageUsed` is 107,374,182,400 bytes (100 GiB).
- `TotalBackupStorageBilled` represents the sum, in bytes, of `BackupRetentionPeriodStorageUsed` and `SnapshotStorageUsed`, minus an amount of free backup storage, which equals the size of the cluster volume for one day. The free backup storage is equal to the latest volume size. For example if your cluster's `VolumeBytesUsed` size is 100 GiB, your retention period is two days, and you have one manual snapshot outside the retention period, the `TotalBackupStorageBilled` is 214,748,364,800 bytes (200 GiB + 100 GiB - 100 GiB).
- These metrics are computed independently for each Aurora DB cluster.

You can monitor your Aurora clusters and build reports using CloudWatch metrics through the [CloudWatch console](#). For more information about how to use CloudWatch metrics, see [Availability of Aurora metrics in the Amazon RDS console \(p. 649\)](#).

The backtrack setting for an Aurora DB cluster doesn't affect the volume of backup data for that cluster. Amazon bills the storage for backtrack data separately. You can also find the backtrack pricing information on the [Amazon Aurora pricing](#) web page.

If you share a snapshot with another user, you are still the owner of that snapshot. The storage costs apply to the snapshot owner. If you delete a shared snapshot that you own, nobody can access it. To keep access to a shared snapshot owned by someone else, you can copy that snapshot. Doing so makes you the owner of the new snapshot. Any storage costs for the copied snapshot apply to your account.

Creating a DB cluster snapshot

Amazon RDS creates a storage volume snapshot of your DB cluster, backing up the entire DB cluster and not just individual databases. When you create a DB cluster snapshot, you need to identify which DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later. The amount of time it takes to create a DB cluster snapshot varies with the size of your databases. Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects the amount of time it takes to create the snapshot.

Unlike automated backups, manual snapshots aren't subject to the backup retention period. Snapshots don't expire.

For very long-term backups, we recommend exporting snapshot data to Amazon S3. If the major version of your DB engine is no longer supported, you can't restore to that version from a snapshot. For more information, see [Exporting DB snapshot data to Amazon S3 \(p. 518\)](#).

You can create a DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

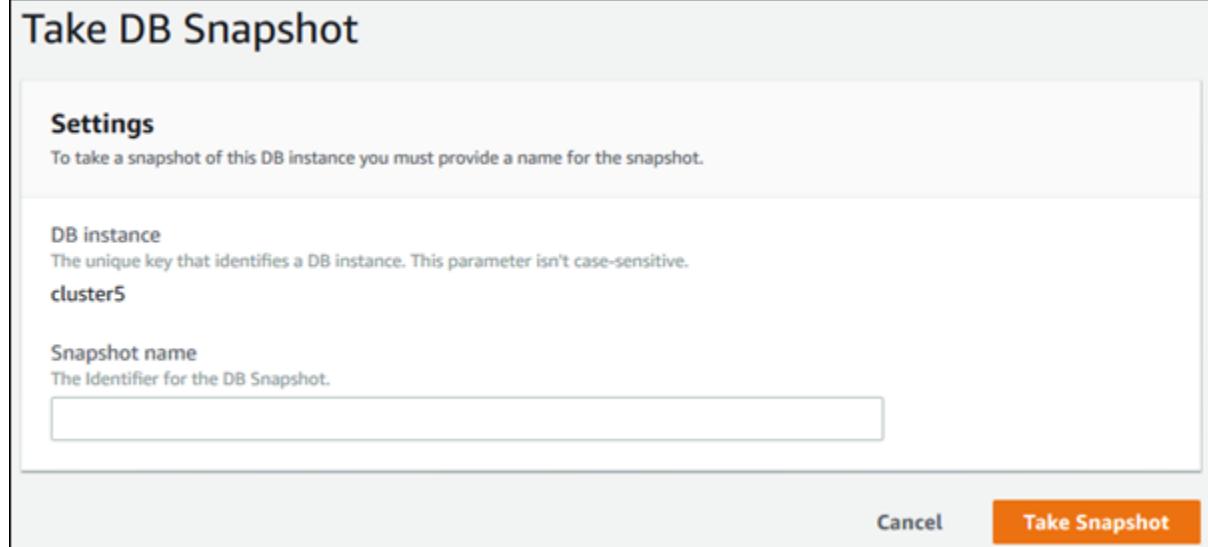

Console

To create a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. In the list of DB instances, choose a writer instance for the DB cluster.
4. Choose **Actions**, and then choose **Take snapshot**.

The **Take DB Snapshot** window appears.

5. Enter the name of the DB cluster snapshot in the **Snapshot name** box.

6. Choose **Take Snapshot**.

AWS CLI

When you create a DB cluster snapshot using the AWS CLI, you need to identify which DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later.

You can do this by using the AWS CLI [create-db-cluster-snapshot](#) command with the following parameters:

- `--db-cluster-identifier`
- `--db-cluster-snapshot-identifier`

In this example, you create a DB cluster snapshot named `mydbclustersnapshot` for a DB cluster called `mydbcluster`.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster-snapshot \
--db-cluster-identifier mydbcluster \
--db-cluster-snapshot-identifier mydbclustersnapshot
```

For Windows:

```
aws rds create-db-cluster-snapshot ^
--db-cluster-identifier mydbcluster ^
--db-cluster-snapshot-identifier mydbclustersnapshot
```

RDS API

When you create a DB cluster snapshot using the Amazon RDS API, you need to identify which DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later. You can do this by using the Amazon RDS API [CreateDBClusterSnapshot](#) command with the following parameters:

- `DBClusterIdentifier`
- `DBClusterSnapshotIdentifier`

Determining whether the DB cluster snapshot is available

You can check that the DB cluster snapshot is available by looking under **Snapshots** on the **Maintenance & backups** tab on the detail page for the cluster in the AWS Management Console, by using the [describe-db-cluster-snapshots](#) CLI command, or by using the [DescribeDBClusterSnapshots](#) API action.

You can also use the [wait db-cluster-snapshot-available](#) CLI command to poll the API every 30 seconds until the snapshot is available.

Restoring from a DB cluster snapshot

Amazon RDS creates a storage volume snapshot of your DB cluster, backing up the entire DB instance and not just individual databases. You can create a new DB cluster by restoring from a DB snapshot. You provide the name of the DB cluster snapshot to restore from, and then provide a name for the new DB cluster that is created from the restore. You can't restore from a DB cluster snapshot to an existing DB cluster; a new DB cluster is created when you restore.

You can use the restored DB cluster as soon as its status is available.

You can use AWS CloudFormation to restore a DB cluster from a DB cluster snapshot. For more information, see [AWS::RDS::DBCluster](#) in the *AWS CloudFormation User Guide*.

Note

Sharing a manual DB cluster snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to directly restore a DB cluster from the snapshot instead of taking a copy of it and restoring from that. For more information, see [Sharing a DB cluster snapshot \(p. 510\)](#).

Parameter group considerations

We recommend that you retain the DB parameter group and DB cluster parameter group for any DB cluster snapshots you create, so that you can associate your restored DB cluster with the correct parameter groups.

The default DB parameter group and DB cluster parameter group are associated with the restored cluster, unless you choose different ones. No custom parameter settings are available in the default parameter groups.

You can specify the parameter groups when you restore the DB cluster.

For more information about DB parameter groups and DB cluster parameter groups, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#).

Security group considerations

When you restore a DB cluster, the default virtual private cloud (VPC), DB subnet group, and VPC security group are associated with the restored instance, unless you choose different ones.

- If you're using the Amazon RDS console, you can specify a custom VPC security group to associate with the cluster or create a new VPC security group.
- If you're using the AWS CLI, you can specify a custom VPC security group to associate with the cluster by including the `--vpc-security-group-ids` option in the `restore-db-cluster-from-snapshot` command.
- If you're using the Amazon RDS API, you can include the `VpcSecurityGroupIds.VpcSecurityGroupId.N` parameter in the `RestoreDBClusterFromSnapshot` action.

As soon as the restore is complete and your new DB cluster is available, you can also change the VPC settings by modifying the DB cluster. For more information, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

Amazon Aurora considerations

With Aurora, you restore a DB cluster snapshot to a DB cluster.

With both Aurora MySQL and Aurora PostgreSQL, you can also restore a DB cluster snapshot to an Aurora Serverless DB cluster. For more information, see [Restoring an Aurora Serverless v1 DB cluster \(p. 166\)](#).

With Aurora MySQL, you can restore a DB cluster snapshot from a cluster without parallel query to a cluster with parallel query. Because parallel query is typically used with very large tables, the snapshot mechanism is the fastest way to ingest large volumes of data to an Aurora MySQL parallel query-enabled cluster. For more information, see [Working with parallel query for Amazon Aurora MySQL \(p. 881\)](#).

Restoring from a snapshot

You can restore a DB cluster from a DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore a DB cluster from a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB cluster snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore snapshot** page, for **DB instance identifier**, enter the name for your restored DB cluster.
6. Choose **Restore DB instance**.

AWS CLI

To restore a DB cluster from a DB cluster snapshot, use the AWS CLI command [restore-db-cluster-from-snapshot](#).

In this example, you restore from a previously created DB cluster snapshot named `mydbclustersnapshot`. You restore to a new DB cluster named `mynewdbcluster`.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
--db-cluster-identifier mynewdbcluster \
--snapshot-identifier mydbclustersnapshot \
--engine aurora/aurora-mysql/aurora-postgresql
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
--db-cluster-identifier mynewdbcluster ^
--snapshot-identifier mydbclustersnapshot ^
--engine aurora/aurora-mysql/aurora-postgresql
```

After the DB cluster has been restored, you must add the DB cluster to the security group used by the DB cluster used to create the DB cluster snapshot if you want the same functionality as that of the previous DB cluster.

Important

If you use the console to restore a DB cluster, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to restore a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster. Call the [create-db-instance](#) AWS CLI command to create the primary instance for your DB cluster. Include the name of the DB cluster as the --db-cluster-identifier option value.

RDS API

To restore a DB cluster from a DB cluster snapshot, call the RDS API operation [RestoreDBClusterFromSnapshot](#) with the following parameters:

- `DBClusterIdentifier`
- `SnapshotIdentifier`

Important

If you use the console to restore a DB cluster, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the RDS API to restore a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster. Call the RDS API operation [CreateDBInstance](#) to create the primary instance for your DB cluster. Include the name of the DB cluster as the `DBClusterIdentifier` parameter value.

Copying a DB cluster snapshot

With Amazon RDS, you can copy automated backups or manual DB cluster snapshots. After you copy a snapshot, the copy is a manual snapshot. You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

You can copy a snapshot within the same AWS Region, you can copy a snapshot across AWS Regions, and you can copy shared snapshots.

You can't copy a DB cluster snapshot across Regions and accounts in a single step. Perform one step for each of these copy actions. As an alternative to copying, you can also share manual snapshots with other AWS accounts. For more information, see [Sharing a DB cluster snapshot \(p. 510\)](#).

Note

Amazon bills you based upon the amount of Amazon Aurora backup and snapshot data you keep and the period of time that you keep it. For information about the storage associated with Aurora backups and snapshots, see [Understanding Aurora backup storage usage \(p. 494\)](#). For pricing information about Aurora storage, see [Amazon RDS for Aurora pricing](#).

Limitations

The following are some limitations when you copy snapshots:

- You can't copy a snapshot to or from the China (Beijing) or China (Ningxia) Regions.
- You can copy a snapshot between AWS GovCloud (US-East) and AWS GovCloud (US-West). However, you can't copy a snapshot between these AWS GovCloud (US) Regions and commercial AWS Regions.
- If you delete a source snapshot before the target snapshot becomes available, the snapshot copy might fail. Verify that the target snapshot has a status of `AVAILABLE` before you delete a source snapshot.
- You can have up to five snapshot copy requests in progress to a single destination Region per account.
- Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete. In some cases, there might be a large number of cross-Region snapshot copy requests from a given source Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copy starts.

Snapshot retention

Amazon RDS deletes automated backups in several situations:

- At the end of their retention period.
- When you disable automated backups for a DB cluster.
- When you delete a DB cluster.

If you want to keep an automated backup for a longer period, copy it to create a manual snapshot, which is retained until you delete it. Amazon RDS storage costs might apply to manual snapshots if they exceed your default storage space.

For more information about backup storage costs, see [Amazon RDS pricing](#).

Copying shared snapshots

You can copy snapshots shared to you by other AWS accounts. In some cases, you might copy an encrypted snapshot that has been shared from another AWS account. In these cases, you must have access to the AWS KMS key that was used to encrypt the snapshot.

You can only copy a shared DB cluster snapshot, whether encrypted or not, in the same AWS Region. For more information, see [Sharing encrypted snapshots \(p. 511\)](#).

Handling encryption

You can copy a snapshot that has been encrypted using a KMS key. If you copy an encrypted snapshot, the copy of the snapshot must also be encrypted. If you copy an encrypted snapshot within the same AWS Region, you can encrypt the copy with the same KMS key as the original snapshot. Or you can specify a different KMS key.

If you copy an encrypted snapshot across Regions, you must specify a KMS key valid in the destination AWS Region. It can be a Region-specific KMS key, or a multi-Region key. For more information on multi-Region KMS keys, see [Using multi-Region keys in AWS KMS](#).

The source snapshot remains encrypted throughout the copy process. For more information, see [Limitations of Amazon Aurora encrypted DB clusters \(p. 1712\)](#).

Note

For Amazon Aurora DB cluster snapshots, you can't encrypt an unencrypted DB cluster snapshot when you copy the snapshot.

Incremental snapshot copying

Aurora doesn't support incremental snapshot copying. Aurora DB cluster snapshot copies are always full copies. A full snapshot copy contains all of the data and metadata required to restore the DB cluster.

Cross-Region snapshot copying

You can copy DB cluster snapshots across AWS Regions. However, there are certain constraints and considerations for cross-Region snapshot copying.

Cross-Region copying of DB cluster snapshots isn't supported in the following opt-in AWS Regions:

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Europe (Milan)
- Middle East (Bahrain)

Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete.

In some cases, there might be a large number of cross-Region snapshot copy requests from a given source AWS Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source AWS Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copying starts.

Parameter group considerations

When you copy a snapshot across Regions, the copy doesn't include the parameter group used by the original DB cluster. When you restore a snapshot to create a new DB cluster, that DB cluster gets the default parameter group for the AWS Region it is created in. To give the new DB cluster the same parameters as the original, do the following:

1. In the destination AWS Region, create a DB cluster parameter group with the same settings as the original DB cluster. If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB cluster and add the new or existing parameter group from the previous step.

Copying a DB cluster snapshot

Use the procedures in this topic to copy a DB cluster snapshot. If your source database engine is Aurora, then your snapshot is a DB cluster snapshot.

For each AWS account, you can copy up to five DB cluster snapshots at a time from one AWS Region to another. Copying both encrypted and unencrypted DB cluster snapshots is supported. If you copy a DB cluster snapshot to another AWS Region, you create a manual DB cluster snapshot that is retained in that AWS Region. Copying a DB cluster snapshot out of the source AWS Region incurs Amazon RDS data transfer charges.

For more information about data transfer pricing, see [Amazon RDS pricing](#).

After the DB cluster snapshot copy has been created in the new AWS Region, the DB cluster snapshot copy behaves the same as all other DB cluster snapshots in that AWS Region.

Console

This procedure works for copying encrypted or unencrypted DB cluster snapshots, in the same AWS Region or across Regions.

To cancel a copy operation once it is in progress, delete the target DB cluster snapshot while that DB cluster snapshot is in **copying** status.

To copy a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the check box for the DB cluster snapshot you want to copy.
4. For **Actions**, choose **Copy Snapshot**. The **Make Copy of DB Snapshot** page appears.

New DB Snapshot Identifier

DB Snapshot Identifier for the new snapshot

Copy Tags [Info](#)

i Please note that depending on the amount of data to be copied and the Region you choose, this operation could take several hours to complete and the display on the progress bar could be delayed until setup is complete.

Encryption

Encryption [Info](#)

Enable encryption [Learn more](#) ↗

Select to encrypt the given instance. Master key ids and aliases appear in the list after they have been created using the Key Management Service(KMS) console.

Disable encryption

[Cancel](#)

[Copy Snapshot](#)

5. (Optional) To copy the DB cluster snapshot to a different AWS Region, choose that AWS Region for **Destination Region**.
6. Type the name of the DB cluster snapshot copy in **New DB Snapshot Identifier**.
7. To copy tags and values from the snapshot to the copy of the snapshot, choose **Copy Tags**.
8. Choose **Copy Snapshot**.

Copying an unencrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API

Use the procedures in the following sections to copy an unencrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API.

To cancel a copy operation once it is in progress, delete the target DB cluster snapshot identified by `--target-db-cluster-snapshot-identifier` or `TargetDBClusterSnapshotIdentifier` while that DB cluster snapshot is in **copying** status.

AWS CLI

To copy a DB cluster snapshot, use the AWS CLI [copy-db-cluster-snapshot](#) command. If you are copying the snapshot to another AWS Region, run the command in the AWS Region to which the snapshot will be copied.

The following options are used to copy an unencrypted DB cluster snapshot:

- **--source-db-cluster-snapshot-identifier** – The identifier for the DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- **--target-db-cluster-snapshot-identifier** – The identifier for the new copy of the DB cluster snapshot.

The following code creates a copy of DB cluster snapshot `arn:aws:rds:us-east-1:123456789012:cluster-snapshot:aurora-cluster1-snapshot-20130805` named `myclustersnapshotcopy` in the AWS Region in which the command is run. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-cluster-snapshot \
--source-db-cluster-snapshot-identifier arn:aws:rds:us-east-1:123456789012:cluster-
snapshot:aurora-cluster1-snapshot-20130805 \
--target-db-cluster-snapshot-identifier myclustersnapshotcopy \
--copy-tags
```

For Windows:

```
aws rds copy-db-cluster-snapshot ^
--source-db-cluster-snapshot-identifier arn:aws:rds:us-east-1:123456789012:cluster-
snapshot:aurora-cluster1-snapshot-20130805 ^
--target-db-cluster-snapshot-identifier myclustersnapshotcopy ^
--copy-tags
```

RDS API

To copy a DB cluster snapshot, use the Amazon RDS API [CopyDBClusterSnapshot](#) operation. If you are copying the snapshot to another AWS Region, perform the action in the AWS Region to which the snapshot will be copied.

The following parameters are used to copy an unencrypted DB cluster snapshot:

- **SourceDBClusterSnapshotIdentifier** – The identifier for the DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- **TargetDBClusterSnapshotIdentifier** – The identifier for the new copy of the DB cluster snapshot.

The following code creates a copy of a snapshot `arn:aws:rds:us-east-1:123456789012:cluster-snapshot:aurora-cluster1-snapshot-20130805` named `myclustersnapshotcopy` in the US West (N. California) Region. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

Example

```
https://rds.us-west-1.amazonaws.com/
?Action=CopyDBClusterSnapshot
&CopyTags=true
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&SourceDBSnapshotIdentifier=arn%3Aaws%3Ards%3Aus-east-1%3A123456789012%3Acluster-
snapshot%3Aaurora-cluster1-snapshot-20130805
&TargetDBSnapshotIdentifier=myclustersnapshotcopy
&Version=2013-09-09
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140429/us-west-1/rds/aws4_request
&X-Amz-Date=20140429T175351Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=9164337efa99caf850e874a1cb7ef62f3cea29d0b448b9e0e7c53b288ddffed2
```

Copying an encrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API

Use the procedures in the following sections to copy an encrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API.

To cancel a copy operation once it is in progress, delete the target DB cluster snapshot identified by `--target-db-cluster-snapshot-identifier` or `TargetDBClusterSnapshotIdentifier` while that DB cluster snapshot is in **copying** status.

AWS CLI

To copy a DB cluster snapshot, use the AWS CLI `copy-db-cluster-snapshot` command. If you are copying the snapshot to another AWS Region, run the command in the AWS Region to which the snapshot will be copied.

The following options are used to copy an encrypted DB cluster snapshot:

- `--source-region` – If you are copying the snapshot to another AWS Region, specify the AWS Region that the encrypted DB cluster snapshot will be copied from.

If you are copying the snapshot to another AWS Region and you don't specify `source-region`, you must specify the `pre-signed-url` option instead. The `pre-signed-url` value must be a URL that contains a Signature Version 4 signed request for the `CopyDBClusterSnapshot` action to be called in the source AWS Region where the DB cluster snapshot is copied from. To learn more about the `pre-signed-url`, see `copy-db-cluster-snapshot`.

- `--source-db-cluster-snapshot-identifier` – The identifier for the encrypted DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region. If that is the case, the AWS Region specified in `source-db-cluster-snapshot-identifier` must match the AWS Region specified for `--source-region`.
- `--target-db-cluster-snapshot-identifier` – The identifier for the new copy of the encrypted DB cluster snapshot.
- `--kms-key-id` – The KMS key identifier for the key to use to encrypt the copy of the DB cluster snapshot.

You can optionally use this option if the DB cluster snapshot is encrypted, you copy the snapshot in the same AWS Region, and you want to specify a new KMS key to encrypt the copy. Otherwise, the copy of the DB cluster snapshot is encrypted with the same KMS key as the source DB cluster snapshot.

You must use this option if the DB cluster snapshot is encrypted and you are copying the snapshot to another AWS Region. In that case, you must specify a KMS key for the destination AWS Region.

The following code example copies the encrypted DB cluster snapshot from the US West (Oregon) Region to the US East (N. Virginia) Region. The command is called in the US East (N. Virginia) Region.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-cluster-snapshot \
--source-db-cluster-snapshot-identifier arn:aws:rds:us-west-2:123456789012:cluster-
snapshot:aurora-cluster1-snapshot-20161115 \
--target-db-cluster-snapshot-identifier myclustersnapshotcopy \
--source-region us-west-2 \
--kms-key-id my-us-east-1-key
```

For Windows:

```
aws rds copy-db-cluster-snapshot ^
--source-db-cluster-snapshot-identifier arn:aws:rds:us-west-2:123456789012:cluster-
snapshot:aurora-cluster1-snapshot-20161115 ^
--target-db-cluster-snapshot-identifier myclustersnapshotcopy ^
--source-region us-west-2 ^
--kms-key-id my-us-east-1-key
```

RDS API

To copy a DB cluster snapshot, use the Amazon RDS API [CopyDBClusterSnapshot](#) operation. If you are copying the snapshot to another AWS Region, perform the action in the AWS Region to which the snapshot will be copied.

The following parameters are used to copy an encrypted DB cluster snapshot:

- **SourceDBClusterSnapshotIdentifier** – The identifier for the encrypted DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- **TargetDBClusterSnapshotIdentifier** – The identifier for the new copy of the encrypted DB cluster snapshot.
- **KmsKeyId** – The KMS key identifier for the key to use to encrypt the copy of the DB cluster snapshot.

You can optionally use this parameter if the DB cluster snapshot is encrypted, you copy the snapshot in the same AWS Region, and you specify a new KMS key to use to encrypt the copy. Otherwise, the copy of the DB cluster snapshot is encrypted with the same KMS key as the source DB cluster snapshot.

You must use this parameter if the DB cluster snapshot is encrypted and you are copying the snapshot to another AWS Region. In that case, you must specify a KMS key for the destination AWS Region.

- **PreSignedUrl** – If you are copying the snapshot to another AWS Region, you must specify the **PreSignedUrl** parameter. The **PreSignedUrl** value must be a URL that contains a Signature Version 4 signed request for the `CopyDBClusterSnapshot` action to be called in the source AWS Region where the DB cluster snapshot is copied from. To learn more about using a presigned URL, see [CopyDBClusterSnapshot](#).

To automatically rather than manually generate a presigned URL, use the AWS CLI `copy-db-cluster-snapshot` command with the `--source-region` option instead.

The following code example copies the encrypted DB cluster snapshot from the US West (Oregon) Region to the US East (N. Virginia) Region. The action is called in the US East (N. Virginia) Region.

Example

```
https://rds.us-east-1.amazonaws.com/
?Action=CopyDBClusterSnapshot
&KmsKeyId=my-us-east-1-key
&PreSignedUrl=https%253A%252F%252Frds.us-west-2.amazonaws.com%252F

```

Copying a DB cluster snapshot across accounts

You can enable other AWS accounts to copy DB cluster snapshots that you specify by using the Amazon RDS API `ModifyDBClusterSnapshotAttribute` and `CopyDBClusterSnapshot` actions. You can only copy DB cluster snapshots across accounts in the same AWS Region. The cross-account copying process works as follows, where Account A is making the snapshot available to copy, and Account B is copying it.

1. Using Account A, call `ModifyDBClusterSnapshotAttribute`, specifying `restore` for the `AttributeName` parameter, and the ID for Account B for the `ValuesToAdd` parameter.
2. (If the snapshot is encrypted) Using Account A, update the key policy for the KMS key, first adding the ARN of Account B as a `Principal`, and then allow the `kms:CreateGrant` action.
3. (If the snapshot is encrypted) Using Account B, choose or create an IAM user and attach an IAM policy to that user that allows it to copy an encrypted DB cluster snapshot using your KMS key.
4. Using Account B, call `CopyDBClusterSnapshot` and use the `SourceDBClusterSnapshotIdentifier` parameter to specify the ARN of the DB cluster snapshot to be copied, which must include the ID for Account A.

To list all of the AWS accounts permitted to restore a DB cluster snapshot, use the `DescribeDBSnapshotAttributes` or `DescribeDBClusterSnapshotAttributes` API operation.

To remove sharing permission for an AWS account, use the `ModifyDBSnapshotAttribute` or `ModifyDBClusterSnapshotAttribute` action with `AttributeName` set to `restore` and the ID of the account to remove in the `ValuesToRemove` parameter.

Copying an unencrypted DB cluster snapshot to another account

Use the following procedure to copy an unencrypted DB cluster snapshot to another account in the same AWS Region.

1. In the source account for the DB cluster snapshot, call `ModifyDBClusterSnapshotAttribute`, specifying `restore` for the `AttributeName` parameter, and the ID for the target account for the `ValuesToAdd` parameter.

Running the following example using the account 987654321 permits two AWS account identifiers, 123451234512 and 123456789012, to restore the DB cluster snapshot named manual-snapshot1.

```
https://rds.us-west-2.amazonaws.com/
?Action=ModifyDBClusterSnapshotAttribute
&AttributeName=restore
&DBClusterSnapshotIdentifier=manual-snapshot1
&SignatureMethod=HmacSHA256&SignatureVersion=4
&ValuesToAdd.member.1=123451234512
&ValuesToAdd.member.2=123456789012
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20150922/us-west-2/rds/aws4_request
&X-Amz-Date=20150922T220515Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=ef38f1ce3dab4e1dbf113d8d2a265c67d17ece1999ffd36be85714ed36ddbb3
```

2. In the target account, call `CopyDBClusterSnapshot` and use the `SourceDBClusterSnapshotIdentifier` parameter to specify the ARN of the DB cluster snapshot to be copied, which must include the ID for the source account.

Running the following example using the account 123451234512 copies the DB cluster snapshot aurora-cluster1-snapshot-20130805 from account 987654321 and creates a DB cluster snapshot named dbclustersnapshot1.

```
https://rds.us-west-2.amazonaws.com/
?Action=CopyDBClusterSnapshot
&CopyTags=true
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&SourceDBClusterSnapshotIdentifier=arn:aws:rds:us-west-2:987654321:cluster-
snapshot:aurora-cluster1-snapshot-20130805
&TargetDBClusterSnapshotIdentifier=dbclustersnapshot1
&Version=2013-09-09
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20150922/us-west-2/rds/aws4_request
&X-Amz-Date=20140429T175351Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=9164337efa99caf850e874a1cb7ef62f3cea29d0b448b9e0e7c53b288ddffed2
```

Copying an encrypted DB cluster snapshot to another account

Use the following procedure to copy an encrypted DB cluster snapshot to another account in the same AWS Region.

1. In the source account for the DB cluster snapshot, call `ModifyDBClusterSnapshotAttribute`, specifying `restore` for the `AttributeName` parameter, and the ID for the target account for the `ValuesToAdd` parameter.

Running the following example using the account 987654321 permits two AWS account identifiers, 123451234512 and 123456789012, to restore the DB cluster snapshot named manual-snapshot1.

```
https://rds.us-west-2.amazonaws.com/
?Action=ModifyDBClusterSnapshotAttribute
&AttributeName=restore
&DBClusterSnapshotIdentifier>manual-snapshot1
&SignatureMethod=HmacSHA256&SignatureVersion=4
&ValuesToAdd.member.1=123451234512
&ValuesToAdd.member.2=123456789012
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20150922/us-west-2/rds/aws4_request
&X-Amz-Date=20150922T220515Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=ef38f1ce3dab4e1dbf113d8d2a265c67d17ece1999ffd36be85714ed36ddbb3
```

2. In the source account for the DB cluster snapshot, update the key policy for the KMS key, first adding the ARN of the target account as a Principal, and then allow the `kms:CreateGrant` action. For more information, see [Allowing access to an AWS KMS key \(p. 511\)](#).
3. In the target account, choose or create an IAM user and attach an IAM policy to that user that allows it to copy an encrypted DB cluster snapshot using your KMS key. For more information, see [Creating an IAM policy to enable copying of the encrypted snapshot \(p. 512\)](#).
4. In the target account, call `CopyDBClusterSnapshot` and use the `SourceDBClusterSnapshotIdentifier` parameter to specify the ARN of the DB cluster snapshot to be copied, which must include the ID for the source account.

Running the following example using the account 123451234512 copies the DB cluster snapshot aurora-cluster1-snapshot-20130805 from account 987654321 and creates a DB cluster snapshot named dbclustersnapshot1.

```
https://rds.us-west-2.amazonaws.com/
?Action=CopyDBClusterSnapshot
&CopyTags=true
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&SourceDBClusterSnapshotIdentifier=arn:aws:rds:us-west-2:987654321:cluster-
snapshot:aurora-cluster1-snapshot-20130805
&TargetDBClusterSnapshotIdentifier=dbclustersnapshot1
&Version=2013-09-09
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140429T175351Z
&X-Amz-Date=20140429T175351Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=9164337efa99caf850e874a1cb7ef62f3cea29d0b448b9e0e7c53b288ddffed2
```

Sharing a DB cluster snapshot

Using Amazon RDS, you can share a manual DB cluster snapshot in the following ways:

- Sharing a manual DB cluster snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to copy the snapshot.
- Sharing a manual DB cluster snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to directly restore a DB cluster from the snapshot instead of taking a copy of it and restoring from that.

Note

To share an automated DB cluster snapshot, create a manual DB cluster snapshot by copying the automated snapshot, and then share that copy. This process also applies to AWS Backup-generated resources.

For more information on copying a snapshot, see [Copying a DB cluster snapshot \(p. 500\)](#). For more information on restoring a DB instance from a DB cluster snapshot, see [Restoring from a DB cluster snapshot \(p. 497\)](#).

For more information on restoring a DB cluster from a DB cluster snapshot, see [Overview of backing up and restoring an Aurora DB cluster \(p. 491\)](#).

You can share a manual snapshot with up to 20 other AWS accounts.

The following limitation applies when sharing manual snapshots with other AWS accounts:

- When you restore a DB cluster from a shared snapshot using the AWS Command Line Interface (AWS CLI) or Amazon RDS API, you must specify the Amazon Resource Name (ARN) of the shared snapshot as the snapshot identifier.

Sharing public snapshots

You can also share an unencrypted manual snapshot as public, which makes the snapshot available to all AWS accounts. Make sure when sharing a snapshot as public that none of your private information is included in the public snapshot.

When a snapshot is shared publicly, it gives all AWS accounts permission both to copy the snapshot and to create DB clusters from it.

You aren't billed for the backup storage of public snapshots owned by other accounts. You're billed only for snapshots that you own.

If you copy a public snapshot, you own the copy. You're billed for the backup storage of your snapshot copy. If you create a DB cluster from a public snapshot, you're billed for that DB cluster. For Amazon Aurora pricing information, see the [Aurora pricing page](#).

You can delete only the public snapshots that you own. To delete a shared or public snapshot, make sure to log into the AWS account that owns the snapshot.

Viewing public snapshots owned by other AWS accounts

You can view public snapshots owned by other accounts in a particular AWS Region on the **Public** tab of the **Snapshots** page in the Amazon RDS console. Your snapshots (those owned by your account) don't appear on this tab.

To view public snapshots

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Public** tab.

The public snapshots appear. You can see which account owns a public snapshot in the **Owner** column.

Note

You might have to modify the page preferences, by selecting the gear icon at the upper right of the **Public snapshots** list, to see this column.

Viewing your own public snapshots

You can use the following AWS CLI command (Unix only) to view the public snapshots owned by your AWS account in a particular AWS Region.

```
aws rds describe-db-cluster-snapshots --snapshot-type public --include-public |  
grep account_number
```

The output returned is similar to the following example if you have public snapshots.

```
"DBClusterSnapshotArn": "arn:aws:rds:us-west-2:123456789012:cluster-  
snapshot:myclustersnapshot1",  
"DBClusterSnapshotArn": "arn:aws:rds:us-west-2:123456789012:cluster-  
snapshot:myclustersnapshot2",
```

Sharing encrypted snapshots

You can share DB cluster snapshots that have been encrypted "at rest" using the AES-256 encryption algorithm, as described in [Encrypting Amazon Aurora resources \(p. 1709\)](#). To do this, take the following steps:

1. Share the AWS KMS key that was used to encrypt the snapshot with any accounts that you want to be able to access the snapshot.

You can share KMS keys with another AWS account by adding the other account to the KMS key policy. For details on updating a key policy, see [Key policies](#) in the *AWS KMS Developer Guide*. For an example of creating a key policy, see [Allowing access to an AWS KMS key \(p. 511\)](#) later in this topic.
2. Use the AWS Management Console, AWS CLI, or Amazon RDS API to share the encrypted snapshot with the other accounts.

These restrictions apply to sharing encrypted snapshots:

- You can't share encrypted snapshots as public.
- You can't share a snapshot that has been encrypted using the default KMS key of the AWS account that shared the snapshot.

Allowing access to an AWS KMS key

For another AWS account to copy an encrypted DB cluster snapshot shared from your account, the account that you share your snapshot with must have access to the AWS KMS key that encrypted the snapshot.

To allow another AWS account access to a KMS key, update the key policy for the KMS key. You update it with the Amazon Resource Name (ARN) of the AWS account that you are sharing to as `Principal` in the KMS key policy. Then you allow the `kms:CreateGrant` action.

After you have given an AWS account access to your KMS key, to copy your encrypted snapshot that AWS account must create an AWS Identity and Access Management (IAM) role or user if it doesn't already have one. In addition, that AWS account must also attach an IAM policy to that IAM role or user that allows the role or user to copy an encrypted DB cluster snapshot using your KMS key. The account must be an IAM user and cannot be a root AWS account identity due to AWS KMS security restrictions.

In the following key policy example, user `111122223333` is the owner of the KMS key, and user `444455556666` is the account that the key is being shared with. This updated key policy gives the AWS account access to the KMS key by including the ARN for the root AWS account identity for user `444455556666` as a `Principal` for the policy, and by allowing the `kms:CreateGrant` action.

```
{
  "Id": "key-policy-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Allow use of the key",
      "Effect": "Allow",
      "Principal": {"AWS": [
        "arn:aws:iam::111122223333:user/KeyUser",
        "arn:aws:iam::444455556666:root"
      ]},
      "Action": [
        "kms:CreateGrant",
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
      ],
      "Resource": "*"
    },
    {
      "Sid": "Allow attachment of persistent resources",
      "Effect": "Allow",
      "Principal": {"AWS": [
        "arn:aws:iam::111122223333:user/KeyUser",
        "arn:aws:iam::444455556666:root"
      ]},
      "Action": [
        "kms:CreateGrant",
        "kms>ListGrants",
        "kms:RevokeGrant"
      ],
      "Resource": "*",
      "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
    }
  ]
}
```

Creating an IAM policy to enable copying of the encrypted snapshot

Once the external AWS account has access to your KMS key, the owner of that AWS account can create a policy that allows an IAM user created for that account to copy an encrypted snapshot encrypted with that KMS key.

The following example shows a policy that can be attached to an IAM user for AWS account `444455556666` that enables the IAM user to copy a shared snapshot from AWS account `111122223333`

that has been encrypted with the KMS key `c989c1dd-a3f2-4a5d-8d96-e793d082ab26` in the `us-west-2` region.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowUseOfTheKey",  
            "Effect": "Allow",  
            "Action": [  
                "kms:Encrypt",  
                "kms:Decrypt",  
                "kms:ReEncrypt*",  
                "kms:GenerateDataKey*",  
                "kms:DescribeKey",  
                "kms:CreateGrant",  
                "kms:RetireGrant"  
            ],  
            "Resource": ["arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-e793d082ab26"]  
        },  
        {  
            "Sid": "AllowAttachmentOfPersistentResources",  
            "Effect": "Allow",  
            "Action": [  
                "kms:CreateGrant",  
                "kms>ListGrants",  
                "kms:RevokeGrant"  
            ],  
            "Resource": ["arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-e793d082ab26"],  
            "Condition": {  
                "Bool": {  
                    "kms:GrantIsForAWSResource": true  
                }  
            }  
        }  
    ]  
}
```

For details on updating a key policy, see [Key policies in the AWS KMS Developer Guide](#).

Sharing a snapshot

You can share a DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

Using the Amazon RDS console, you can share a manual DB cluster snapshot with up to 20 AWS accounts. You can also use the console to stop sharing a manual snapshot with one or more accounts.

To share a manual DB cluster snapshot by using the Amazon RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the manual snapshot that you want to share.
4. For **Actions**, choose **Share Snapshot**.

5. Choose one of the following options for **DB snapshot visibility**.
 - If the source is unencrypted, choose **Public** to permit all AWS accounts to restore a DB cluster from your manual DB cluster snapshot, or choose **Private** to permit only AWS accounts that you specify to restore a DB cluster from your manual DB cluster snapshot.
6. For **AWS Account ID**, type the AWS account identifier for an account that you want to permit to restore a DB cluster from your manual snapshot, and then choose **Add**. Repeat to include additional AWS account identifiers, up to 20 AWS accounts.

If you make an error when adding an AWS account identifier to the list of permitted accounts, you can delete it from the list by choosing **Delete** at the right of the incorrect AWS account identifier.

Snapshot permissions

Preferences

You are sharing an unencrypted DB snapshot. When you share an unencrypted DB snapshot, you give the other account permission to make a copy of the DB snapshot and to restore a database from your DB snapshot.

DB snapshot
testoracletags-snap

DB snapshot visibility
 Private
 Public

AWS account ID

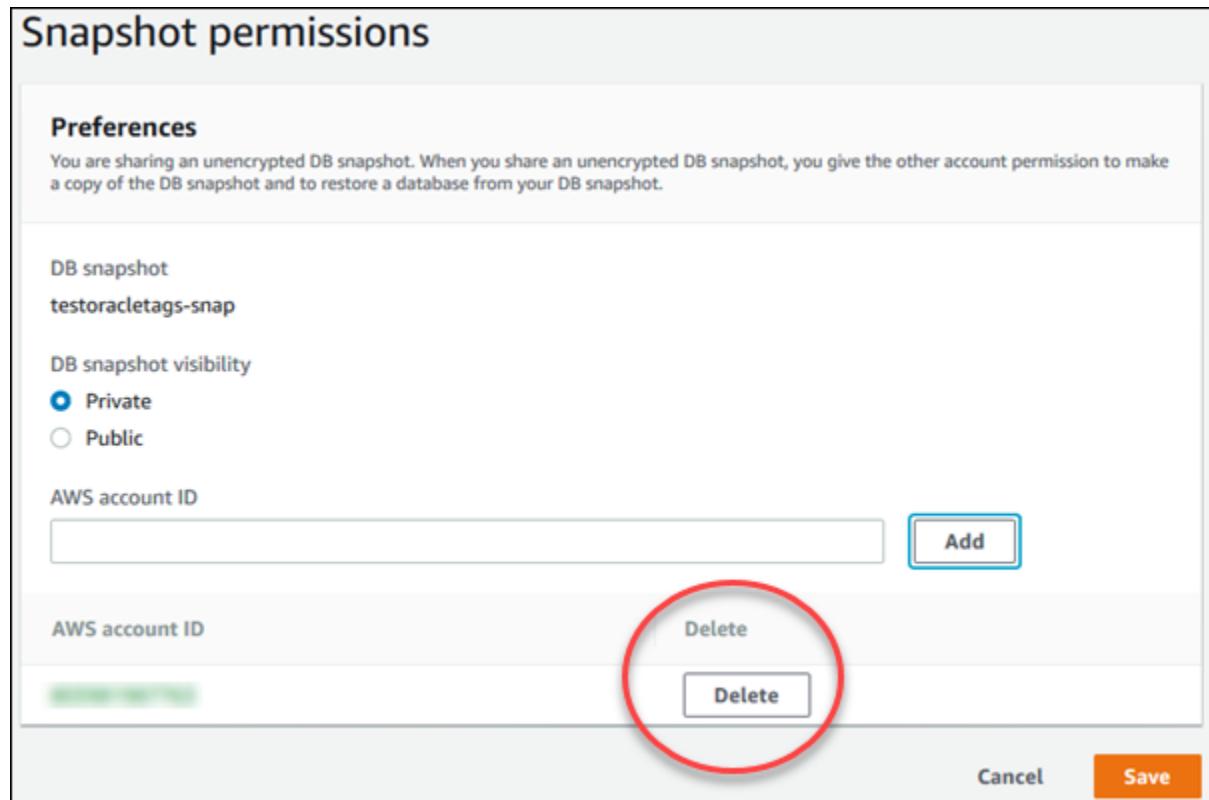

AWS account ID	Delete
Please add AWS account ID	

7. After you have added identifiers for all of the AWS accounts that you want to permit to restore the manual snapshot, choose **Save** to save your changes.

To stop sharing a manual DB cluster snapshot with an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the manual snapshot that you want to stop sharing.
4. Choose **Actions**, and then choose **Share Snapshot**.

- To remove permission for an AWS account, choose **Delete** for the AWS account identifier for that account from the list of authorized accounts.

- Choose **Save** to save your changes.

AWS CLI

To share a DB cluster snapshot, use the `aws rds modify-db-cluster-snapshot-attribute` command. Use the `--values-to-add` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

Example of sharing a snapshot with a single account

The following example enables AWS account identifier 123456789012 to restore the DB cluster snapshot named `cluster-3-snapshot`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-snapshot-attribute \
--db-cluster-snapshot-identifier cluster-3-snapshot \
--attribute-name restore \
--values-to-add 123456789012
```

For Windows:

```
aws rds modify-db-cluster-snapshot-attribute ^
--db-cluster-snapshot-identifier cluster-3-snapshot ^
--attribute-name restore ^
--values-to-add 123456789012
```

Example of sharing a snapshot with multiple accounts

The following example enables two AWS account identifiers, 111122223333 and 444455556666, to restore the DB cluster snapshot named manual-cluster-snapshot1.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-snapshot-attribute \
--db-cluster-snapshot-identifier manual-cluster-snapshot1 \
--attribute-name restore \
--values-to-add {"111122223333","444455556666"}
```

For Windows:

```
aws rds modify-db-cluster-snapshot-attribute ^
--db-cluster-snapshot-identifier manual-cluster-snapshot1 ^
--attribute-name restore ^
--values-to-add "[\"111122223333\", \"444455556666\"]"
```

Note

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

To remove an AWS account identifier from the list, use the --values-to-remove parameter.

Example of stopping snapshot sharing

The following example prevents AWS account ID 444455556666 from restoring the snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-snapshot-attribute \
--db-cluster-snapshot-identifier manual-cluster-snapshot1 \
--attribute-name restore \
--values-to-remove 444455556666
```

For Windows:

```
aws rds modify-db-cluster-snapshot-attribute ^
--db-cluster-snapshot-identifier manual-cluster-snapshot1 ^
--attribute-name restore ^
--values-to-remove 444455556666
```

To list the AWS accounts enabled to restore a snapshot, use the [describe-db-cluster-snapshot-attributes](#) AWS CLI command.

RDS API

You can also share a manual DB cluster snapshot with other AWS accounts by using the Amazon RDS API. To do so, call the [ModifyDBClusterSnapshotAttribute](#) operation. Specify `restore` for `AttributeName`, and use the `ValuesToAdd` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

To make a manual snapshot public and restorable by all AWS accounts, use the value `all`. However, take care not to add the `all` value for any manual snapshots that contain private information that you don't want to be available to all AWS accounts. Also, don't specify `all` for encrypted snapshots, because making such snapshots public isn't supported.

To remove sharing permission for an AWS account, use the [ModifyDBClusterSnapshotAttribute](#) operation with `AttributeName` set to `restore` and the `ValuesToRemove` parameter. To mark a manual snapshot as private, remove the value `all` from the values list for the `restore` attribute.

To list all of the AWS accounts permitted to restore a snapshot, use the [DescribeDBClusterSnapshotAttributes](#) API operation.

Exporting DB snapshot data to Amazon S3

You can export DB snapshot data to an Amazon S3 bucket. The export process runs in the background and doesn't affect the performance of your active DB cluster.

When you export a DB snapshot, Amazon Aurora extracts data from the snapshot and stores it in an Amazon S3 bucket. The data is stored in an Apache Parquet format that is compressed and consistent.

You can export manual snapshots and automated system snapshots. By default, all data in the snapshot is exported. However, you can choose to export specific sets of databases, schemas, or tables.

After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information on using Athena to read Parquet data, see [Parquet SerDe](#) in the *Amazon Athena User Guide*. For more information on using Redshift Spectrum to read Parquet data, see [COPY from columnar data formats](#) in the *Amazon Redshift Database Developer Guide*.

Amazon RDS supports exporting snapshots in all AWS Regions except the following:

- Asia Pacific (Jakarta)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

The following table shows the Aurora MySQL engine versions that are supported for exporting snapshot data to Amazon S3. For more information about Aurora MySQL engine versions, see [Database engine updates for Amazon Aurora MySQL \(p. 1082\)](#).

Aurora MySQL version	MySQL-compatible version
3.01.0 and higher	8.0
2.04.4 and higher	5.7
1.19.2 and higher	5.6

The following table shows the Aurora PostgreSQL engine versions that are supported for exporting snapshot data to Amazon S3. For more information about Aurora PostgreSQL engine versions, see [Amazon Aurora PostgreSQL releases and engine versions \(p. 1599\)](#).

Aurora PostgreSQL version	PostgreSQL-compatible version
13.3 and higher	13.3 and higher
4.0 and higher	12.4 and higher
3.0 and higher	11.4 and higher
2.2 and higher	10.6 and higher
1.4 and higher	9.6.11 and higher

Topics

Limitations

Exporting DB snapshot data to Amazon S3 has the following limitations:

- If a database, schema, or table has characters in its name other than the following, partial export isn't supported. However, you can export the entire DB snapshot.
 - Latin letters (A–Z)
 - Digits (0–9)
 - Dollar symbol (\$)
 - Underscore (_)
- Spaces () and certain characters aren't supported in database table column names. Tables with the following characters in column names are skipped during export:

```
, ; { } ( ) \n \t = (space)
```

- If the data contains a large object such as a BLOB or CLOB, close to or greater than 500 MB, the export fails.
- If a table contains a large row close to or greater than 2 GB, the table is skipped during export.

Overview of exporting snapshot data

You use the following process to export DB snapshot data to an Amazon S3 bucket. For more details, see the following sections.

1. Identify the snapshot to export.

Use an existing automated or manual snapshot, or create a manual snapshot of a DB instance.

2. Set up access to the Amazon S3 bucket.

A *bucket* is a container for Amazon S3 objects or files. To provide the information to access a bucket, take the following steps:

- a. Identify the S3 bucket where the snapshot is to be exported to. The S3 bucket must be in the same AWS Region as the snapshot. For more information, see [Identifying the Amazon S3 bucket for export \(p. 520\)](#).
 - b. Create an AWS Identity and Access Management (IAM) role that grants the snapshot export task access to the S3 bucket. For more information, see [Providing access to an Amazon S3 bucket using an IAM role \(p. 520\)](#).
3. Create a symmetric AWS KMS key for the server-side encryption. The KMS key is used by the snapshot export task to set up AWS KMS server-side encryption when writing the export data to S3. For more information, see [Encrypting Amazon Aurora resources \(p. 1709\)](#).

The KMS key is also used for local disk encryption at rest on Amazon EC2. In addition, if you have a deny statement in your KMS key policy, make sure to explicitly exclude the AWS service principal `export.rds.amazonaws.com`.

You can use a KMS key within your AWS account, or you can use a cross-account KMS key. For more information, see [Using a cross-account AWS KMS key for encrypting Amazon S3 exports \(p. 522\)](#).

4. Export the snapshot to Amazon S3 using the console or the `start-export-task` CLI command. For more information, see [Exporting a snapshot to an Amazon S3 bucket \(p. 523\)](#).
5. To access your exported data in the Amazon S3 bucket, see [Uploading, downloading, and managing objects](#) in the *Amazon Simple Storage Service User Guide*.

Setting up access to an Amazon S3 bucket

To export DB snapshot data to an Amazon S3 file, you first give the snapshot permission to access the Amazon S3 bucket. You then create an IAM role to allow the Amazon Aurora service to write to the Amazon S3 bucket.

Topics

- [Identifying the Amazon S3 bucket for export \(p. 520\)](#)
- [Providing access to an Amazon S3 bucket using an IAM role \(p. 520\)](#)
- [Using a cross-account Amazon S3 bucket \(p. 522\)](#)

Identifying the Amazon S3 bucket for export

Identify the Amazon S3 bucket to export the DB snapshot to. Use an existing S3 bucket or create a new S3 bucket.

Note

The S3 bucket to export to must be in the same AWS Region as the snapshot.

For more information about working with Amazon S3 buckets, see the following in the *Amazon Simple Storage Service User Guide*:

- [How do I view the properties for an S3 bucket?](#)
- [How do I enable default encryption for an Amazon S3 bucket?](#)
- [How do I create an S3 bucket?](#)

Providing access to an Amazon S3 bucket using an IAM role

Before you export DB snapshot data to Amazon S3, give the snapshot export tasks write-access permission to the Amazon S3 bucket.

To do this, create an IAM policy that provides access to the bucket. Then create an IAM role and attach the policy to the role. You later assign the IAM role to your snapshot export task.

Important

If you plan to use the AWS Management Console to export your snapshot, you can choose to create the IAM policy and the role automatically when you export the snapshot. For instructions, see [Exporting a snapshot to an Amazon S3 bucket \(p. 523\)](#).

To give DB snapshot tasks access to Amazon S3

1. Create an IAM policy. This policy provides the bucket and object permissions that allow your snapshot export task to access Amazon S3.

Include in the policy the following required actions to allow the transfer of files from Amazon Aurora to an S3 bucket:

- s3:PutObject*
- s3:GetObject*
- s3>ListBucket
- s3>DeleteObject*
- s3:GetBucketLocation

Include in the policy the following resources to identify the S3 bucket and objects in the bucket. The following list of resources shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- arn:aws:s3:::*your-s3-bucket*
- arn:aws:s3:::*your-s3-bucket*/*

For more information on creating an IAM policy for Amazon Aurora, see [Creating and using an IAM policy for IAM database access \(p. 1746\)](#). See also [Tutorial: Create and attach your first customer managed policy](#) in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `ExportPolicy` with these options. It grants access to a bucket named `your-s3-bucket`.

Note

After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy --policy-name ExportPolicy --policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "ExportPolicy",  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject*",  
                "s3>ListBucket",  
                "s3:GetObject*",  
                "s3>DeleteObject*",  
                "s3:GetBucketLocation"  
            ],  
            "Resource": [  
                "arn:aws:s3:::your-s3-bucket",  
                "arn:aws:s3:::your-s3-bucket/*"  
            ]  
        }  
    ]  
}'
```

2. Create an IAM role. You do this so that Aurora can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

The following example shows using the AWS CLI command to create a role named `rds-s3-export-role`.

```
aws iam create-role --role-name rds-s3-export-role --assume-role-policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": "rds.amazonaws.com",  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}'
```

```
{  
    "Effect": "Allow",  
    "Principal": {  
        "Service": "export.rds.amazonaws.com"  
    },  
    "Action": "sts:AssumeRole"  
}  
]  
}'
```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

Using a cross-account Amazon S3 bucket

You can use Amazon S3 buckets across AWS accounts. To use a cross-account bucket, add a bucket policy to allow access to the IAM role that you're using for the S3 exports. For more information, see [Example 2: Bucket owner granting cross-account bucket permissions](#).

- Attach a bucket policy to your bucket, as shown in the following example.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:role/Admin"  
            },  
            "Action": [  
                "s3:PutObject*",  
                "s3>ListBucket",  
                "s3:GetObject*",  
                "s3>DeleteObject*",  
                "s3:GetBucketLocation"  
            ],  
            "Resource": [  
                "arn:aws:s3:::mycrossaccountbucket",  
                "arn:aws:s3:::mycrossaccountbucket/*"  
            ]  
        }  
    ]  
}
```

Using a cross-account AWS KMS key for encrypting Amazon S3 exports

You can use a cross-account AWS KMS key to encrypt Amazon S3 exports. First, you add a key policy to the local account, then you add IAM policies in the external account. For more information, see [Allowing users in other accounts to use a KMS key](#).

To use a cross-account KMS key

1. Add a key policy to the local account.

The following example gives `ExampleRole` and `ExampleUser` in the external account 444455556666 permissions in the local account 123456789012.

```
{  
    "Sid": "Allow an external account to use this KMS key",  
    "Effect": "Allow",  
    "Principal": {  
        "AWS": [  
            "arn:aws:iam::444455556666:role/ExampleRole",  
            "arn:aws:iam::444455556666:user/ExampleUser"  
        ]  
    },  
    "Action": [  
        "kms:Encrypt",  
        "kms:Decrypt",  
        "kms:ReEncrypt*",  
        "kms:GenerateDataKey*",  
        "kms>CreateGrant",  
        "kms:DescribeKey",  
        "kms:RetireGrant"  
    ],  
    "Resource": "*"  
}
```

2. Add IAM policies to the external account.

The following example IAM policy allows the principal to use the KMS key in account 123456789012 for cryptographic operations. To give this permission to `ExampleRole` and `ExampleUser` in account 444455556666, [attach the policy](#) to them in that account.

```
{  
    "Sid": "Allow use of KMS key in account 123456789012",  
    "Effect": "Allow",  
    "Action": [  
        "kms:Encrypt",  
        "kms:Decrypt",  
        "kms:ReEncrypt*",  
        "kms:GenerateDataKey*",  
        "kms>CreateGrant",  
        "kms:DescribeKey",  
        "kms:RetireGrant"  
    ],  
    "Resource": "arn:aws:kms:us-  
west-2:123456789012:key/1234abcd-12ab-34cd-56ef-1234567890ab"  
}
```

Exporting a snapshot to an Amazon S3 bucket

You can have up to five concurrent DB snapshot export tasks in progress per account.

Note

Exporting RDS snapshots can take a while depending on your database type and size. The export task first restores and scales the entire database before extracting the data to Amazon S3. The task's progress during this phase displays as **Starting**. When the task switches to exporting data to S3, progress displays as **In progress**.

The time it takes for the export to complete depends on the data stored in the database. For example, tables with well-distributed numeric primary key or index columns export the fastest. Tables that don't contain a column suitable for partitioning and tables with only one index on a string-based column take longer. This longer export time occurs because the export uses a slower single-threaded process.

You can export a DB snapshot to Amazon S3 using the AWS Management Console, the AWS CLI, or the RDS API.

If you use a Lambda function to export a snapshot, add the `kms:DescribeKey` action to the Lambda function policy. For more information, see [AWS Lambda permissions](#).

Console

The **Export to Amazon S3** console option appears only for snapshots that can be exported to Amazon S3. A snapshot might not be available for export because of the following reasons:

- The DB engine isn't supported for S3 export.
- The DB instance version isn't supported for S3 export.
- S3 export isn't supported in the AWS Region where the snapshot was created.

To export a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. From the tabs, choose the type of snapshot that you want to export.
4. In the list of snapshots, choose the snapshot that you want to export.
5. For **Actions**, choose **Export to Amazon S3**.

The **Export to Amazon S3** window appears.

6. For **Export identifier**, enter a name to identify the export task. This value is also used for the name of the file created in the S3 bucket.
7. Choose the data to be exported:
 - Choose **All** to export all data in the snapshot.
 - Choose **Partial** to export specific parts of the snapshot. To identify which parts of the snapshot to export, enter one or more databases, schemas, or tables for **Identifiers**, separated by spaces.

Use the following format:

```
database[.schema][.table] database2[.schema2][.table2] ... databasen[.scheman]  
[.tablen]
```

For example:

```
mydatabase mydatabase2.myschema1 mydatabase2.myschema2.mytable1  
mydatabase2.myschema2.mytable2
```

8. For **S3 bucket**, choose the bucket to export to.

To assign the exported data to a folder path in the S3 bucket, enter the optional path for **S3 prefix**.

9. For **IAM role**, either choose a role that grants you write access to your chosen S3 bucket, or create a new role.

- If you created a role by following the steps in [Providing access to an Amazon S3 bucket using an IAM role \(p. 520\)](#), choose that role.
 - If you didn't create a role that grants you write access to your chosen S3 bucket, choose **Create a new role** to create the role automatically. Next, enter a name for the role in **IAM role name**.
10. For **AWS KMS key**, enter the ARN for the key to use for encrypting the exported data.
11. Choose **Export to Amazon S3**.

AWS CLI

To export a DB snapshot to Amazon S3 using the AWS CLI, use the `start-export-task` command with the following required options:

- `--export-task-identifier`
- `--source-arn`
- `--s3-bucket-name`
- `--iam-role-arn`
- `--kms-key-id`

In the following examples, the snapshot export task is named `my-snapshot-export`, which exports a snapshot to an S3 bucket named `my-export-bucket`.

Example

For Linux, macOS, or Unix:

```
aws rds start-export-task \
  --export-task-identifier my-snapshot-export \
  --source-arn arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot-name \
  --s3-bucket-name my-export-bucket \
  --iam-role-arn iam-role \
  --kms-key-id my-key
```

For Windows:

```
aws rds start-export-task ^
  --export-task-identifier my-snapshot-export ^
  --source-arn arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot-name ^
  --s3-bucket-name my-export-bucket ^
  --iam-role-arn iam-role ^
  --kms-key-id my-key
```

Sample output follows.

```
{  
  "Status": "STARTING",  
  "IamRoleArn": "iam-role",  
  "ExportTime": "2019-08-12T01:23:53.109Z",  
  "S3Bucket": "my-export-bucket",  
  "PercentProgress": 0,  
  "KmsKeyId": "my-key",  
  "ExportTaskIdentifier": "my-snapshot-export",  
  "TotalExtractedDataInGB": 0,  
  "TaskStartTime": "2019-11-13T19:46:00.173Z",  
  "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot-name"  
}
```

To provide a folder path in the S3 bucket for the snapshot export, include the `--s3-prefix` option in the [start-export-task](#) command.

RDS API

To export a DB snapshot to Amazon S3 using the Amazon RDS API, use the [StartExportTask](#) operation with the following required parameters:

- `ExportTaskIdentifier`
- `SourceArn`
- `S3BucketName`
- `IamRoleArn`
- `KmsKeyId`

Monitoring snapshot exports

You can monitor DB snapshot exports using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To monitor DB snapshot exports

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. To view the list of snapshot exports, choose the **Exports in Amazon S3** tab.
4. To view information about a specific snapshot export, choose the export task.

AWS CLI

To monitor DB snapshot exports using the AWS CLI, use the [describe-export-tasks](#) command.

The following example shows how to display current information about all of your snapshot exports.

Example

```
aws rds describe-export-tasks
{
    "ExportTasks": [
        {
            "Status": "CANCELED",
            "TaskEndTime": "2019-11-01T17:36:46.961Z",
            "S3Prefix": "something",
            "ExportTime": "2019-10-24T20:23:48.364Z",
            "S3Bucket": "examplebucket",
            "PercentProgress": 0,
            "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
            "ExportTaskIdentifier": "anewtest",
            "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
            "TotalExtractedDataInGB": 0,
            "TaskStartTime": "2019-10-25T19:10:58.885Z",
            "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:parameter-groups-test"
    ]
}
```

```

        },
        {
            "Status": "COMPLETE",
            "TaskEndTime": "2019-10-31T21:37:28.312Z",
            "WarningMessage": "{\"skippedTables\":[],\"skippedObjectives\":[],\"general\":[" +
                "{\"reason\":\"FAILED_TO_EXTRACT_TABLES_LIST_FOR_DATABASE\"}]}",
            "S3Prefix": "",
            "ExportTime": "2019-10-31T06:44:53.452Z",
            "S3Bucket": "examplebucket1",
            "PercentProgress": 100,
            "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/2Zp9Utk/
h3yCo8nvbEXAMPLEKEY",
            "ExportTaskIdentifier": "thursday-events-test",
            "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
            "TotalExtractedDataInGB": 263,
            "TaskStartTime": "2019-10-31T20:58:06.998Z",
            "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:rds:example-1-2019-10-31-06-44"
        },
        {
            "Status": "FAILED",
            "TaskEndTime": "2019-10-31T02:12:36.409Z",
            "FailureCause": "The S3 bucket edgcuc-export isn't located in the current AWS Region. Please, review your S3 bucket name and retry the export.",
            "S3Prefix": "",
            "ExportTime": "2019-10-30T06:45:04.526Z",
            "S3Bucket": "examplebucket2",
            "PercentProgress": 0,
            "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/2Zp9Utk/
h3yCo8nvbEXAMPLEKEY",
            "ExportTaskIdentifier": "wednesday-afternoon-test",
            "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
            "TotalExtractedDataInGB": 0,
            "TaskStartTime": "2019-10-30T22:43:40.034Z",
            "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:rds:example-1-2019-10-30-06-45"
        }
    ]
}

```

To display information about a specific snapshot export, include the `--export-task-identifier` option with the `describe-export-tasks` command. To filter the output, include the `--Filters` option. For more options, see the [describe-export-tasks](#) command.

RDS API

To display information about DB snapshot exports using the Amazon RDS API, use the [DescribeExportTasks](#) operation.

To track completion of the export workflow or to trigger another workflow, you can subscribe to Amazon Simple Notification Service topics. For more information on Amazon SNS, see [Using Amazon RDS event notification \(p. 675\)](#).

Cancelling a snapshot export task

You can cancel a DB snapshot export task using the AWS Management Console, the AWS CLI, or the RDS API.

Note

Canceling a snapshot export task doesn't remove any data that was exported to Amazon S3. For information about how to delete the data using the console, see [How do I delete objects from an S3 bucket?](#) To delete the data using the CLI, use the `delete-object` command.

Console

To cancel a snapshot export task

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Exports in Amazon S3** tab.
4. Choose the snapshot export task that you want to cancel.
5. Choose **Cancel**.
6. Choose **Cancel export task** on the confirmation page.

AWS CLI

To cancel a snapshot export task using the AWS CLI, use the `cancel-export-task` command. The command requires the `--export-task-identifier` option.

Example

```
aws rds cancel-export-task --export-task-identifier my_export
{
    "Status": "CANCELING",
    "S3Prefix": "",
    "ExportTime": "2019-08-12T01:23:53.109Z",
    "S3Bucket": "examplebucket",
    "PercentProgress": 0,
    "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
    "ExportTaskIdentifier": "my_export",
    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 0,
    "TaskStartTime": "2019-11-13T19:46:00.173Z",
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:export-example-1"
}
```

RDS API

To cancel a snapshot export task using the Amazon RDS API, use the `CancelExportTask` operation with the `ExportTaskIdentifier` parameter.

Failure messages for Amazon S3 export tasks

The following table describes the messages that are returned when Amazon S3 export tasks fail.

Failure message	Description
An unknown internal error occurred.	The task has failed because of an unknown error, exception, or failure.
An unknown internal error occurred writing the export task's metadata to the S3 bucket [bucket name].	The task has failed because of an unknown error, exception, or failure.
The RDS export failed to write the export task's metadata because it can't assume the IAM role [role ARN].	The export task assumes your IAM role to validate whether it is allowed to write metadata to your S3 bucket. If the task can't assume your IAM role, it fails.

Failure message	Description
The RDS export failed to write the export task's metadata to the S3 bucket [bucket name] using the IAM role [role ARN] with the KMS key [key ID]. Error code: [error code]	<p>One or more permissions are missing, so the export task can't access the S3 bucket. This failure message is raised when receiving one of the following:</p> <ul style="list-style-type: none"> • <code>AWSecurityTokenServiceException</code> with the error code <code>AccessDenied</code> • <code>AmazonS3Exception</code> with the error code <code>NoSuchBucket</code>, <code>AccessDenied</code>, <code>KMS.InvalidStateException</code>, <code>403 Forbidden</code>, or <code>KMS.DisabledException</code> <p>This means that there are settings misconfigured among the IAM role, S3 bucket, or KMS key.</p>
The IAM role [role ARN] isn't authorized to call [S3 action] on the S3 bucket [bucket name]. Review your permissions and retry the export.	The IAM policy is misconfigured. Permission for the specific S3 action on the S3 bucket is missing. This causes the export task to fail.
KMS key check failed. Check the credentials on your KMS key and try again.	The KMS key credential check failed.
S3 credential check failed. Check the permissions on your S3 bucket and IAM policy.	The S3 credential check failed.
The S3 bucket [bucket name] isn't valid. Either it isn't located in the current AWS Region or it doesn't exist. Review your S3 bucket name and retry the export.	The S3 bucket is invalid.
The S3 bucket [bucket name] isn't located in the current AWS Region. Review your S3 bucket name and retry the export.	The S3 bucket is in the wrong AWS Region.

Troubleshooting PostgreSQL permissions errors

When exporting PostgreSQL databases to Amazon S3, you might see a `PERMISSIONS_DO_NOT_EXIST` error stating that certain tables were skipped. This is usually caused by the superuser, which you specify when creating the DB instance, not having permissions to access those tables.

To fix this error, run the following command:

```
GRANT ALL PRIVILEGES ON ALL TABLES IN SCHEMA schema_name TO superuser_name
```

For more information on superuser privileges, see [Master user account privileges \(p. 1782\)](#).

File naming convention

Exported data for specific tables is stored in the format `base_prefix/files`, where the base prefix is the following:

```
export_identifier/database_name/schema_name.table_name/
```

For example:

```
export-1234567890123-459/rdststdb/rdststdb.DataInsert_7ADB5D19965123A2/
```

There are two conventions for how files are named. The current convention is the following:

```
partition_index/part-00000-random_uuid.format-based_extension
```

For example:

```
1/part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet  
2/part-00000-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet  
3/part-00000-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet
```

The older convention is the following:

```
part-partition_index-random_uuid.format-based_extension
```

For example:

```
part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet  
part-00001-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet  
part-00002-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet
```

The file naming convention is subject to change. Therefore, when reading target tables we recommend that you read everything inside the base prefix for the table.

Data conversion when exporting to an Amazon S3 bucket

When you export a DB snapshot to an Amazon S3 bucket, Amazon Aurora converts data to, exports data in, and stores data in the Parquet format. For more information about Parquet, see the [Apache Parquet](#) website.

Parquet stores all data as one of the following primitive types:

- BOOLEAN
- INT32
- INT64
- INT96
- FLOAT
- DOUBLE
- BYTE_ARRAY – A variable-length byte array, also known as binary
- FIXED_LEN_BYTE_ARRAY – A fixed-length byte array used when the values have a constant size

The Parquet data types are few to reduce the complexity of reading and writing the format. Parquet provides logical types for extending primitive types. A *logical type* is implemented as an annotation with the data in a `LogicalType` metadata field. The logical type annotation explains how to interpret the primitive type.

When the `STRING` logical type annotates a `BYTE_ARRAY` type, it indicates that the byte array should be interpreted as a UTF-8 encoded character string. After an export task completes, Amazon Aurora notifies

you if any string conversion occurred. The underlying data exported is always the same as the data from the source. However, due to the encoding difference in UTF-8, some characters might appear different from the source when read in tools such as Athena.

For more information, see [Parquet logical type definitions](#) in the Parquet documentation.

Topics

- [MySQL data type mapping to Parquet \(p. 531\)](#)
- [PostgreSQL data type mapping to Parquet \(p. 533\)](#)

MySQL data type mapping to Parquet

The following table shows the mapping from MySQL data types to Parquet data types when data is converted and exported to Amazon S3.

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
Numeric data types			
BIGINT	INT64		
BIGINT UNSIGNED	FIXED_LEN_BYTE_ARRAY(9)DECIMAL(20,0)		Parquet supports only signed types, so the mapping requires an additional byte (8 plus 1) to store the BIGINT_UNSIGNED type.
BIT	BYTE_ARRAY		
DECIMAL	INT32	DECIMAL(p,s)	If the source value is less than 2^{31} , it's stored as INT32.
	INT64	DECIMAL(p,s)	If the source value is 2^{31} or greater, but less than 2^{63} , it's stored as INT64.
	FIXED_LEN_BYTE_ARRAY(ND)DECIMAL(p,s)		If the source value is 2^{63} or greater, it's stored as FIXED_LEN_BYTE_ARRAY(N).
	BYTE_ARRAY	STRING	Parquet doesn't support Decimal precision greater than 38. The Decimal value is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
DOUBLE	DOUBLE		
FLOAT	DOUBLE		
INT	INT32		

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
INT UNSIGNED	INT64		
MEDIUMINT	INT32		
MEDIUMINT UNSIGNED	INT64		
NUMERIC	INT32	DECIMAL(p,s)	If the source value is less than 2^{31} , it's stored as INT32.
	INT64	DECIMAL(p,s)	If the source value is 2^{31} or greater, but less than 2^{63} , it's stored as INT64.
	FIXED_LEN_ARRAY(N)	DECIMAL(p,s)	If the source value is 2^{63} or greater, it's stored as FIXED_LEN_BYTE_ARRAY(N).
	BYTE_ARRAY	STRING	Parquet doesn't support Numeric precision greater than 38. This Numeric value is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
SMALLINT	INT32		
SMALLINT UNSIGNED	INT32		
TINYINT	INT32		
TINYINT UNSIGNED	INT32		
String data types			
BINARY	BYTE_ARRAY		
BLOB	BYTE_ARRAY		
CHAR	BYTE_ARRAY		
ENUM	BYTE_ARRAY	STRING	
LINESTRING	BYTE_ARRAY		
LONGBLOB	BYTE_ARRAY		
LONGTEXT	BYTE_ARRAY	STRING	
MEDIUMBLOB	BYTE_ARRAY		
MEDIUMTEXT	BYTE_ARRAY	STRING	
MULTILINESTRING	BYTE_ARRAY		
SET	BYTE_ARRAY	STRING	
TEXT	BYTE_ARRAY	STRING	

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
TINYBLOB	BYTE_ARRAY		
TINYTEXT	BYTE_ARRAY	STRING	
VARBINARY	BYTE_ARRAY		
VARCHAR	BYTE_ARRAY	STRING	
Date and time data types			
DATE	BYTE_ARRAY	STRING	A date is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
DATETIME	INT64	TIMESTAMP_MICROS	
TIME	BYTE_ARRAY	STRING	A TIME type is converted to a string in a BYTE_ARRAY and encoded as UTF8.
TIMESTAMP	INT64	TIMESTAMP_MICROS	
YEAR	INT32		
Geometric data types			
GEOMETRY	BYTE_ARRAY		
GEOMETRYCOLLECTION	BYTE_ARRAY		
MULTIPOINT	BYTE_ARRAY		
MULTIPOLYGON	BYTE_ARRAY		
POINT	BYTE_ARRAY		
POLYGON	BYTE_ARRAY		
JSON data type			
JSON	BYTE_ARRAY	STRING	

PostgreSQL data type mapping to Parquet

The following table shows the mapping from PostgreSQL data types to Parquet data types when data is converted and exported to Amazon S3.

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
Numeric data types			
BIGINT	INT64		

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
BIGSERIAL	INT64		
DECIMAL	BYTE_ARRAY	STRING	A DECIMAL type is converted to a string in a BYTE_ARRAY type and encoded as UTF8. This conversion is to avoid complications due to data precision and data values that are not a number (NaN).
DOUBLE PRECISION	DOUBLE		
INTEGER	INT32		
MONEY	BYTE_ARRAY	STRING	
REAL	FLOAT		
SERIAL	INT32		
SMALLINT	INT32	INT_16	
SMALLSERIAL	INT32	INT_16	
String and related data types			
ARRAY	BYTE_ARRAY	STRING	An array is converted to a string and encoded as BINARY (UTF8). This conversion is to avoid complications due to data precision, data values that are not a number (NaN), and time data values.
BIT	BYTE_ARRAY	STRING	
BIT VARYING	BYTE_ARRAY	STRING	
BYTEA	BINARY		
CHAR	BYTE_ARRAY	STRING	
CHAR(N)	BYTE_ARRAY	STRING	
ENUM	BYTE_ARRAY	STRING	
NAME	BYTE_ARRAY	STRING	
TEXT	BYTE_ARRAY	STRING	
TEXT SEARCH	BYTE_ARRAY	STRING	

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
VARCHAR(N)	BYTE_ARRAY	STRING	
XML	BYTE_ARRAY	STRING	
Date and time data types			
DATE	BYTE_ARRAY	STRING	
INTERVAL	BYTE_ARRAY	STRING	
TIME	BYTE_ARRAY	STRING	
TIME WITH TIME ZONE	BYTE_ARRAY	STRING	
TIMESTAMP	BYTE_ARRAY	STRING	
TIMESTAMP WITH TIME ZONE	BYTE_ARRAY	STRING	
Geometric data types			
BOX	BYTE_ARRAY	STRING	
CIRCLE	BYTE_ARRAY	STRING	
LINE	BYTE_ARRAY	STRING	
LINESEGMENT	BYTE_ARRAY	STRING	
PATH	BYTE_ARRAY	STRING	
POINT	BYTE_ARRAY	STRING	
POLYGON	BYTE_ARRAY	STRING	
JSON data types			
JSON	BYTE_ARRAY	STRING	
JSONB	BYTE_ARRAY	STRING	
Other data types			
BOOLEAN	BOOLEAN		
CIDR	BYTE_ARRAY	STRING	Network data type
COMPOSITE	BYTE_ARRAY	STRING	
DOMAIN	BYTE_ARRAY	STRING	
INET	BYTE_ARRAY	STRING	Network data type
MACADDR	BYTE_ARRAY	STRING	
OBJECT IDENTIFIER	N/A		
PG_LSN	BYTE_ARRAY	STRING	
RANGE	BYTE_ARRAY	STRING	

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
UUID	BYTE_ARRAY	STRING	

Restoring a DB cluster to a specified time

You can restore a DB cluster to a specific point in time, creating a new DB cluster.

When you restore a DB cluster to a point in time, you can choose the default virtual private cloud (VPC) security group. Or you can apply a custom VPC security group to your DB cluster.

Restored DB clusters are automatically associated with the default DB cluster and DB parameter groups. However, you can apply custom parameter groups by specifying them during a restore.

Amazon RDS uploads transaction logs for DB clusters to Amazon S3 continuously. To see the latest restorable time for a DB cluster, use the AWS CLI [describe-db-clusters](#) command and look at the value returned in the `LatestRestorableTime` field for the DB cluster.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for a DB cluster, use the AWS CLI [describe-db-clusters](#) command and look at the value returned in the `EarliestRestorableTime` field for the DB cluster.

Note

Information in this topic applies to Amazon Aurora. For information on restoring an Amazon RDS DB instance, see [Restoring a DB instance to a specified time](#).

For more information about backing up and restoring an Aurora DB cluster, see [Overview of backing up and restoring an Aurora DB cluster \(p. 491\)](#).

For Aurora MySQL, you can restore a provisioned DB cluster to an Aurora Serverless DB cluster.

For more information, see [Restoring an Aurora Serverless v1 DB cluster \(p. 166\)](#).

You can restore a DB cluster to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore a DB cluster to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

The **Restore to point in time** window appears.

5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

If you chose **Custom**, enter the date and time to which you want to restore the cluster.

Note

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

6. For **DB instance identifier**, enter the name of the target restored DB cluster. The name must be unique.
7. Choose other options as needed, such as DB instance class and storage.
8. Choose **Restore to point in time**.

AWS CLI

To restore a DB cluster to a specified time, use the AWS CLI command [restore-db-cluster-to-point-in-time](#) to create a new DB cluster.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
--source-db-cluster-identifier mysourcedbcluster \
--db-cluster-identifier mytargetdbcluster \
--restore-to-time 2017-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
--source-db-cluster-identifier mysourcedbcluster ^
--db-cluster-identifier mytargetdbcluster ^
--restore-to-time 2017-10-14T23:45:00.000Z
```

Important

If you use the console to restore a DB cluster to a specified time, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to restore a DB cluster to a specified time, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

To create the primary instance for your DB cluster, call the [create-db-instance](#) AWS CLI command. Include the name of the DB cluster as the `--db-cluster-identifier` option value.

RDS API

To restore a DB cluster to a specified time, call the Amazon RDS API

[RestoreDBClusterToPointInTime](#) operation with the following parameters:

- `SourceDBClusterIdentifier`
- `DBClusterIdentifier`
- `RestoreToTime`

Important

If you use the console to restore a DB cluster to a specified time, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the RDS API to restore a DB cluster to a specified time, make sure to explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

To create the primary instance for your DB cluster, call the RDS API operation [CreateDBInstance](#). Include the name of the DB cluster as the `DBClusterIdentifier` parameter value.

Deleting a DB cluster snapshot

You can delete DB cluster snapshots managed by Amazon RDS when you no longer need them.

Note

To delete backups managed by AWS Backup, use the AWS Backup console. For information about AWS Backup, see the [AWS Backup Developer Guide](#).

Deleting a DB cluster snapshot

You can delete a DB cluster snapshot using the console, the AWS CLI, or the RDS API.

To delete a shared or public snapshot, you must sign in to the AWS account that owns the snapshot.

Console

To delete a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB cluster snapshot that you want to delete.
4. For **Actions**, choose **Delete Snapshot**.
5. Choose **Delete** on the confirmation page.

AWS CLI

You can delete a DB cluster snapshot by using the AWS CLI command [delete-db-cluster-snapshot](#).

The following options are used to delete a DB cluster snapshot.

- `--db-cluster-snapshot-identifier` – The identifier for the DB cluster snapshot.

Example

The following code deletes the `mydbclustersnapshot` DB cluster snapshot.

For Linux, macOS, or Unix:

```
aws rds delete-db-cluster-snapshot \
--db-cluster-snapshot-identifier mydbclustersnapshot
```

For Windows:

```
aws rds delete-db-cluster-snapshot ^
--db-cluster-snapshot-identifier mydbclustersnapshot
```

RDS API

You can delete a DB cluster snapshot by using the Amazon RDS API operation [DeleteDBClusterSnapshot](#).

The following parameters are used to delete a DB cluster snapshot.

- **DBClusterSnapshotIdentifier** – The identifier for the DB cluster snapshot.

Monitoring metrics in an Amazon Aurora cluster

Amazon Aurora uses a cluster of replicated database servers. Typically, monitoring an Aurora cluster requires checking the health of multiple DB instances. The instances might have specialized roles, handling mostly write operations, only read operations, or a combination. You also monitor the overall health of the cluster by measuring the *replication lag*. This is the amount of time for changes made by one DB instance to be available to the other instances.

- [Monitoring tools \(p. 543\)](#)

Monitoring plan

Before you start monitoring Amazon Aurora, create a monitoring plan. This plan should answer the following questions:

- What are your monitoring goals?
- Which resources will you monitor?
- How often will you monitor these resources?
- Which monitoring tools will you use?
- Who will perform the monitoring tasks?
- Whom should be notified when something goes wrong?

Performance baseline

To achieve your monitoring goals, you need to establish a baseline. To do this, measure performance under different load conditions at various times in your Amazon Aurora environment. You can monitor metrics such as the following:

- Network throughput
- Client connections
- I/O for read, write, or metadata operations
- Burst credit balances for your DB instances

We recommend that you store historical performance data for Amazon Aurora. Using the stored data, you can compare current performance against past trends. You can also distinguish normal performance patterns from anomalies, and devise techniques to address issues.

Performance guidelines

In general, acceptable values for performance metrics depend on what your application is doing relative to your baseline. Investigate consistent or trending variances from your baseline. The following metrics are often the source of performance issues:

- **High CPU or RAM consumption** – High values for CPU or RAM consumption might be appropriate, if they're in keeping with your goals for your application (like throughput or concurrency) and are expected.

- **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.
- **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and internet connection. Investigate network traffic if throughput is consistently lower than expected.
- **Database connections** – If you see high numbers of user connections and also decreases in instance performance and response time, consider constraining database connections. The best number of user connections for your DB instance varies based on your instance class and the complexity of the operations being performed. To determine the number of database connections, associate your DB instance with a parameter group where the `User_Connections` parameter is set to a value other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#).
- **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure that your typical working set fits into memory to minimize read and write operations.

When performance falls outside your established baseline, you might need to make changes to optimize your database availability for your workload. For example, you might need to change the instance class of your DB instance. Or you might need to change the number of DB instances and read replicas that are available for clients.

Monitoring tools

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your other AWS solutions. AWS provides various monitoring tools to watch Amazon Aurora, report when something is wrong, and take automatic actions when appropriate.

Topics

- [Automated monitoring tools \(p. 543\)](#)
- [Manual monitoring tools \(p. 544\)](#)

Automated monitoring tools

We recommend that you automate monitoring tasks as much as possible.

Topics

- [Amazon Aurora cluster status and recommendations \(p. 543\)](#)
- [Amazon CloudWatch metrics for Amazon Aurora \(p. 544\)](#)
- [Amazon RDS Performance Insights and operating-system monitoring \(p. 544\)](#)
- [Integrated services \(p. 544\)](#)

Amazon Aurora cluster status and recommendations

You can use the following automated tools to watch Amazon Aurora and report when something is wrong:

- **Amazon Aurora cluster status** — View details about the current status of your cluster by using the Amazon RDS console, the AWS CLI, or the RDS API.

- **Amazon Aurora recommendations** — Respond to automated recommendations for database resources, such as DB instances, DB clusters, and DB cluster parameter groups. For more information, see [Viewing Amazon Aurora recommendations \(p. 558\)](#).

Amazon CloudWatch metrics for Amazon Aurora

Amazon Aurora integrates with Amazon CloudWatch for additional monitoring capabilities.

- **Amazon CloudWatch** – This service monitors your AWS resources and the applications you run on AWS in real time. You can use the following Amazon CloudWatch features with Amazon Aurora:
 - **Amazon CloudWatch metrics** – Amazon Aurora automatically sends metrics to CloudWatch every minute for each active database. You don't get additional charges for Amazon RDS metrics in CloudWatch. For more information, see [Amazon CloudWatch metrics for Amazon Aurora \(p. 633\)](#)
 - **Amazon CloudWatch alarms** – You can watch a single Amazon Aurora metric over a specific time period. You can then perform one or more actions based on the value of the metric relative to a threshold that you set.

Amazon RDS Performance Insights and operating-system monitoring

You can use the following automated tools to monitor Amazon Aurora performance:

- **Amazon RDS Performance Insights** – Assess the load on your database, and determine when and where to take action. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 573\)](#).
- **Amazon RDS Enhanced Monitoring** – Look at metrics in real time for the operating system. For more information, see [Monitoring OS metrics with Enhanced Monitoring \(p. 626\)](#).

Integrated services

The following AWS services are integrated with Amazon Aurora:

- *Amazon EventBridge* is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. For more information, see [Monitoring Amazon Aurora events \(p. 671\)](#).
- *Amazon CloudWatch Logs* lets you monitor, store, and access your log files from Amazon Aurora instances, CloudTrail, and other sources. For more information, see [Monitoring Amazon Aurora log files \(p. 695\)](#).
- *AWS CloudTrail* captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. For more information, see [Monitoring Amazon Aurora API calls in AWS CloudTrail \(p. 710\)](#).
- *Database Activity Streams* is an Amazon Aurora feature that provides a near-real-time stream of the activity in your DB cluster. For more information, see [Monitoring Amazon Aurora with Database Activity Streams \(p. 714\)](#).
- *DevOps Guru for RDS* is a capability of Amazon DevOps Guru that applies machine learning to Performance Insights metrics for Amazon Aurora databases. For more information, see [Analyzing performance anomalies with DevOps Guru for RDS \(p. 623\)](#).

Manual monitoring tools

You need to manually monitor those items that the CloudWatch alarms don't cover. The Amazon RDS, CloudWatch, AWS Trusted Advisor and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your DB instance.

- From the Amazon RDS console, you can monitor the following items for your resources:
 - The number of connections to a DB instance
 - The amount of read and write operations to a DB instance
 - The amount of storage that a DB instance is currently using
 - The amount of memory and CPU being used for a DB instance
 - The amount of network traffic to and from a DB instance
- From the Trusted Advisor dashboard, you can review the following cost optimization, security, fault tolerance, and performance improvement checks:
 - Amazon RDS Idle DB Instances
 - Amazon RDS Security Group Access Risk
 - Amazon RDS Backups
 - Amazon RDS Multi-AZ
 - Aurora DB Instance Accessibility

For more information on these checks, see [Trusted Advisor best practices \(checks\)](#).

- CloudWatch home page shows:
 - Current alarms and status
 - Graphs of alarms and resources
 - Service health status

In addition, you can use CloudWatch to do the following:

- Create [customized dashboards](#) to monitor the services that you care about.
- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all your AWS resource metrics.
- Create and edit alarms to be notified of problems.

Viewing cluster status and recommendations

Using the Amazon RDS console, you can quickly access the status of your DB cluster and respond to Amazon Aurora recommendations.

Topics

- [Viewing an Amazon Aurora DB cluster \(p. 547\)](#)
- [Viewing DB cluster status \(p. 553\)](#)
- [Viewing DB instance status in an Aurora cluster \(p. 555\)](#)
- [Viewing Amazon Aurora recommendations \(p. 558\)](#)

Viewing an Amazon Aurora DB cluster

You have several options for viewing information about your Amazon Aurora DB clusters and the DB instances in your DB clusters.

- You can view DB clusters and DB instances in the Amazon RDS console by choosing **Databases** from the navigation pane.
- You can get DB cluster and DB instance information using the AWS Command Line Interface (AWS CLI).
- You can get DB cluster and DB instance information using the Amazon RDS API.

Console

In the Amazon RDS console, you can see details about a DB cluster by choosing **Databases** from the console's navigation pane. You can also see details about DB instances that are members of an Amazon Aurora DB cluster on the **Databases** page.

The **Databases** list shows all of the DB clusters for your AWS account. When you choose a DB cluster, you see both information about the DB cluster and also a list of the DB instances that are members of that DB cluster. You can choose the identifier for a DB instance in the list to go directly to the details page for that DB instance in the RDS console.

To view the details page for a DB cluster, choose **Databases** in the navigation pane, and then choose the name of the DB cluster.

You can modify your DB cluster by choosing **Databases** from the console's navigation pane to go to the **Databases** list. To modify a DB cluster, select the DB cluster from the **Databases** list and choose **Modify**.

To modify a DB instance that is a member of a DB cluster, choose **Databases** from the console's navigation pane to go to the **Databases** list.

For example, the following image shows the details page for the DB cluster named `aurora-test`. The DB cluster has four DB instances shown in the **DB identifier** list. The writer DB instance, `dbinstance4`, is the primary DB instance for the DB cluster.

aurora-test

AWS CLI

To view DB cluster information by using the AWS CLI, use the [describe-db-clusters](#) command. For example, the following AWS CLI command lists the DB cluster information for all of the DB clusters in the `us-east-1` region for the configured AWS account.

```
aws rds describe-db-clusters --region us-east-1
```

The command returns the following output if your AWS CLI is configured for JSON output.

```
{  
    "DBClusters": [  
        {  
            "Status": "available",  
            "Engine": "aurora",  
            "Endpoint": "sample-cluster1.cluster-123456789012.us-east-1.rds.amazonaws.com",

        "PreferredMaintenanceWindow": "sun:03:53-sun:04:23"
    }
]
}
```

RDS API

To view DB cluster information using the Amazon RDS API, use the [DescribeDBClusters](#) operation. For example, the following Amazon RDS API command lists the DB cluster information for all of the DB clusters in the us-east-1 region.

```
https://rds.us-east-1.amazonaws.com/
?Action=DescribeDBClusters
&MaxRecords=100
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140722/us-east-1/rds/aws4_request
&X-Amz-Date=20140722T200807Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=2d4f2b9e8abc31122b5546f94c0499bba47de813cb875f9b9c78e8e19c9afe1b
```

The action returns the following output:

```
<DescribeDBClustersResponse xmlns="http://rds.amazonaws.com/doc/2014-10-31/">
<DescribeDBClustersResult>
<DBClusters>
<DBCluster>
<Engine>aurora5.6</Engine>
<Status>available</Status>
<BackupRetentionPeriod>0</BackupRetentionPeriod>
<DBSubnetGroup>my-subgroup</DBSubnetGroup>

```

Viewing DB cluster status

The status of a DB cluster indicates its health. You can view the status of a DB cluster by using the Amazon RDS console, the AWS CLI command [describe-db-clusters](#), or the API operation [DescribeDBClusters](#).

Note

Aurora also uses another status called *maintenance status*, which is shown in the **Maintenance** column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB cluster. Maintenance status is independent of DB cluster status. For more information on *maintenance status*, see [Applying updates for a DB cluster \(p. 445\)](#).

Find the possible status values for DB clusters in the following table.

DB cluster status	Billed	Description
available	Billed	The DB cluster is healthy and available. When an Aurora Serverless cluster is available and paused, you're billed for storage only.
backing-up	Billed	The DB cluster is currently being backed up.
backtracking	Billed	The DB cluster is currently being backtracked. This status only applies to Aurora MySQL.
cloning-failed	Not billed	Cloning a DB cluster failed.
creating	Not billed	The DB cluster is being created. The DB cluster is inaccessible while it is being created.
deleting	Not billed	The DB cluster is being deleted.
failing-over	Billed	A failover from the primary instance to an Aurora Replica is being performed.
inaccessible-encryption-credentials	Not billed	The AWS KMS key used to encrypt or decrypt the DB cluster can't be accessed or recovered.
inaccessible-encryption-credentials-recoverable	Billed for storage	The KMS key used to encrypt or decrypt the DB cluster can't be accessed. However, if the KMS key is active, restarting the DB cluster can recover it. For more information, see Enabling encryption for an Amazon Aurora DB cluster (p. 1710) .
maintenance	Billed	Amazon RDS is applying a maintenance update to the DB cluster. This status is used for DB cluster-level maintenance that RDS schedules well in advance.
migrating	Billed	A DB cluster snapshot is being restored to a DB cluster.
migration-failed	Not billed	A migration failed.
modifying	Billed	The DB cluster is being modified because of a customer request to modify the DB cluster.
promoting	Billed	A read replica is being promoted to a standalone DB cluster.

DB cluster status	Billed	Description
renaming	Billed	The DB cluster is being renamed because of a customer request to rename it.
resetting-master-credentials	Billed	The master credentials for the DB cluster are being reset because of a customer request to reset them.
starting	Billed for storage	The DB cluster is starting.
stopped	Billed for storage	The DB cluster is stopped.
stopping	Billed for storage	The DB cluster is being stopped.
update-iam-db-auth	Billed	IAM authorization for the DB cluster is being updated.
upgrading	Billed	The DB cluster engine version is being upgraded.

Viewing DB instance status in an Aurora cluster

The status of a DB instance in an Aurora cluster indicates the health of the DB instance. You can view the status of a DB instance in a cluster by using the Amazon RDS console, the AWS CLI command [describe-db-instances](#), or the API operation [DescribeDBInstances](#).

Note

Amazon RDS also uses another status called *maintenance status*, which is shown in the **Maintenance** column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB instance. Maintenance status is independent of DB instance status. For more information on *maintenance status*, see [Applying updates for a DB cluster \(p. 445\)](#).

Find the possible status values for DB instances in the following table. This table also shows whether you will be billed for the DB instance and storage, billed only for storage, or not billed. For all DB instance statuses, you are always billed for backup usage.

DB instance status	Billed	Description
available	Billed	The DB instance is healthy and available.
backing-up	Billed	The DB instance is currently being backed up.
backtracking	Billed	The DB instance is currently being backtracked. This status only applies to Aurora MySQL.
configuring-enhanced-monitoring	Billed	Enhanced Monitoring is being enabled or disabled for this DB instance.
configuring-iam-database-auth	Billed	AWS Identity and Access Management (IAM) database authentication is being enabled or disabled for this DB instance.
configuring-log-exports	Billed	Publishing log files to Amazon CloudWatch Logs is being enabled or disabled for this DB instance.
converting-to-vpc	Billed	The DB instance is being converted from a DB instance that is not in an Amazon Virtual Private Cloud (Amazon VPC) to a DB instance that is in an Amazon VPC.
creating	Not billed	The DB instance is being created. The DB instance is inaccessible while it is being created.
deleting	Not billed	The DB instance is being deleted.
failed	Not billed	The DB instance has failed and Amazon RDS can't recover it. Perform a point-in-time restore to the latest restorable time of the DB instance to recover the data.
inaccessible-encryption-credentials	Not billed	The AWS KMS key used to encrypt or decrypt the DB instance can't be accessed or recovered.
inaccessible-encryption-credentials-recoverable	Billed for storage	The KMS key used to encrypt or decrypt the DB instance can't be accessed. However, if the KMS key is active, restarting the DB instance can recover it. For more information, see Enabling encryption for an Amazon Aurora DB cluster (p. 1710) .

DB instance status	Billed	Description
incompatible-network	Not billed	Amazon RDS is attempting to perform a recovery action on a DB instance but can't do so because the VPC is in a state that prevents the action from being completed. This status can occur if, for example, all available IP addresses in a subnet are in use and Amazon RDS can't get an IP address for the DB instance.
incompatible-option-group	Billed	Amazon RDS attempted to apply an option group change but can't do so, and Amazon RDS can't roll back to the previous option group state. For more information, check the Recent Events list for the DB instance. This status can occur if, for example, the option group contains an option such as TDE and the DB instance doesn't contain encrypted information.
incompatible-parameters	Billed	Amazon RDS can't start the DB instance because the parameters specified in the DB instance's DB parameter group aren't compatible with the DB instance. Revert the parameter changes or make them compatible with the DB instance to regain access to your DB instance. For more information about the incompatible parameters, check the Recent Events list for the DB instance.
incompatible-restore	Not billed	Amazon RDS can't do a point-in-time restore. Common causes for this status include using temp tables or using MyISAM tables with MySQL.
insufficient-capacity		Amazon RDS can't create your instance because sufficient capacity isn't currently available. To create your DB instance in the same AZ with the same instance type, delete your DB instance, wait a few hours, and try to create again. Alternatively, create a new instance using a different instance class or AZ.
maintenance	Billed	Amazon RDS is applying a maintenance update to the DB instance. This status is used for instance-level maintenance that RDS schedules well in advance.
modifying	Billed	The DB instance is being modified because of a customer request to modify the DB instance.
moving-to-vpc	Billed	The DB instance is being moved to a new Amazon Virtual Private Cloud (Amazon VPC).
rebooting	Billed	The DB instance is being rebooted because of a customer request or an Amazon RDS process that requires the rebooting of the DB instance.
resetting-master-credentials	Billed	The master credentials for the DB instance are being reset because of a customer request to reset them.
renaming	Billed	The DB instance is being renamed because of a customer request to rename it.
restore-error	Billed	The DB instance encountered an error attempting to restore to a point-in-time or from a snapshot.
starting	Billed for storage	The DB instance is starting.

DB instance status	Billed	Description
stopped	Billed for storage	The DB instance is stopped.
stopping	Billed for storage	The DB instance is being stopped.
storage-full	Billed	The DB instance has reached its storage capacity allocation. This is a critical status, and we recommend that you fix this issue immediately. To do so, scale up your storage by modifying the DB instance. To avoid this situation, set Amazon CloudWatch alarms to warn you when storage space is getting low.
storage-optimization	Billed	Your DB instance is being modified to change the storage size or type. The DB instance is fully operational. However, while the status of your DB instance is storage-optimization , you can't request any changes to the storage of your DB instance. The storage optimization process is usually short, but can sometimes take up to and even beyond 24 hours.
upgrading	Billed	The database engine version is being upgraded.

Viewing Amazon Aurora recommendations

Amazon Aurora provides automated recommendations for database resources, such as DB instances, DB clusters, and DB cluster parameter groups. These recommendations provide best practice guidance by analyzing DB cluster configuration, DB instance configuration, usage, and performance data.

You can find examples of these recommendations in the following table.

Type	Description	Recommendation	Additional information
Nondefault custom memory parameters	Your DB parameter group sets memory parameters that diverge too much from the default values.	Settings that diverge too much from the default values can cause poor performance and errors. We recommend setting custom memory parameters to their default values in the DB parameter group used by the DB instance.	Working with DB parameter groups and DB cluster parameter groups (p. 339)
Change buffering enabled for a MySQL DB instance	Your DB parameter group has change buffering enabled.	Change buffering allows a MySQL DB instance to defer some writes necessary to maintain secondary indexes. This configuration can improve performance slightly, but it can create a large delay in crash recovery. During crash recovery, the secondary index must be brought up to date. So, the benefits of change buffering are outweighed by the potentially very long crash recovery events. We recommend disabling change buffering.	Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog
Logging to table	Your DB parameter group sets logging output to <code>TABLE</code> .	Setting logging output to <code>TABLE</code> uses more storage than setting this parameter to <code>FILE</code> . To avoid reaching the storage limit, we recommend setting the logging output parameter to <code>FILE</code> .	Aurora MySQL database log files (p. 700)
DB cluster with one DB instance	Your DB cluster only contains one DB instance.	For improved performance and availability, we recommend adding another DB instance with the same DB instance class in a different Availability Zone.	High availability for Amazon Aurora (p. 68)
DB cluster in one Availability Zone	Your DB cluster has all of its DB instances in the same Availability Zone.	For improved availability, we recommend adding another DB instance with the same DB instance class in a different Availability Zone.	High availability for Amazon Aurora (p. 68)
DB cluster outdated	Your DB cluster is running an older engine version.	We recommend that you keep your DB cluster at the most current minor version because it includes the latest security and functionality fixes. Unlike major version upgrades, minor version upgrades include only changes	Maintaining an Amazon Aurora DB cluster (p. 443)

Type	Description	Recommendation	Additional information
		that are backward-compatible with previous minor versions (of the same major version) of the DB engine. We recommend that you upgrade to a recent engine version	
DB cluster with different parameter groups	Your DB cluster has different DB parameter groups assigned to its DB instances.	Using different parameter groups can cause incompatibilities between the DB instances. To avoid problems and for easier maintenance, we recommend using the same parameter group for all of the DB instances in the DB cluster.	Working with DB parameter groups and DB cluster parameter groups (p. 339)
DB cluster with different DB instance classes	Your DB cluster has DB instances that use different DB instance classes.	Using different DB instance classes for DB instances can cause problems. For example, performance might suffer if a less powerful DB instance class is promoted to replace a more powerful DB instance class. To avoid problems and for easier maintenance, we recommend using the same DB instance class for all of the DB instances in the DB cluster.	Aurora Replicas (p. 70)

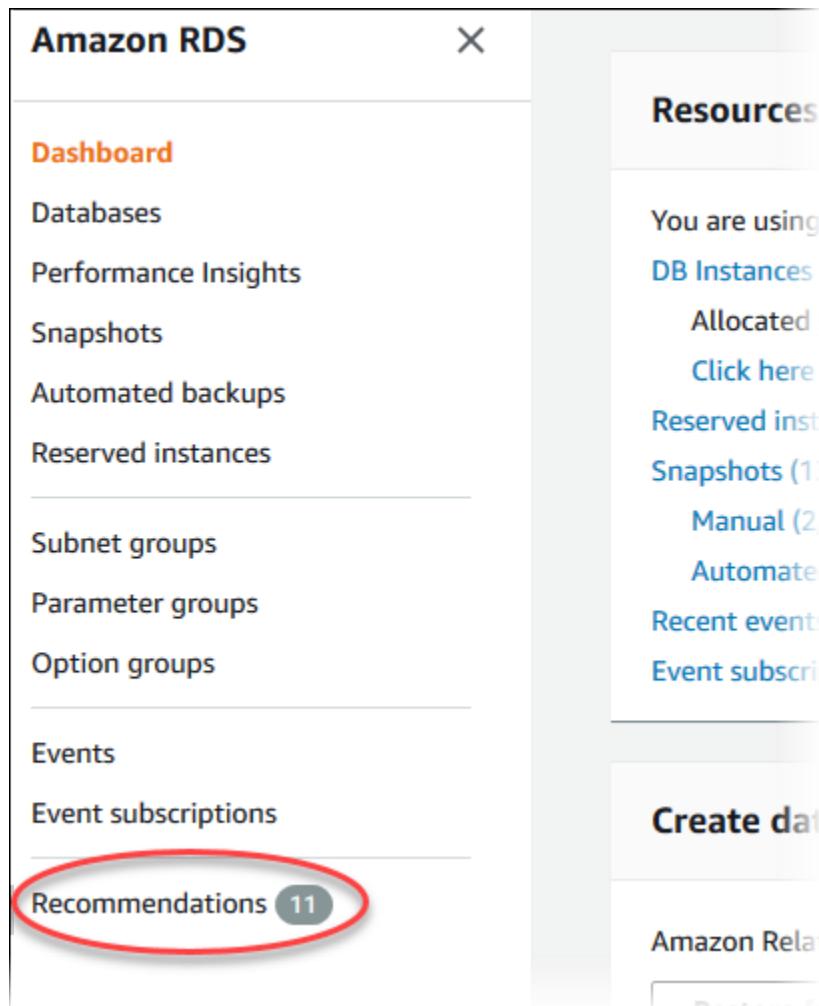

Amazon Aurora generates recommendations for a resource when the resource is created or modified. Amazon Aurora also periodically scans your resources and generates recommendations.

Responding to Amazon Aurora recommendations

You can find recommendations in the AWS Management Console. You can perform the recommended action immediately, schedule it for the next maintenance window, or dismiss it.

To respond to Amazon Aurora recommendations

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Recommendations**.

The Recommendations page appears.

This screenshot shows the 'Recommendations' page. At the top, there are four tabs: Active (2), Dismissed (0), Scheduled (0), and Applied (0). The 'Active (2)' tab is selected. Below the tabs, there are two recommendation items, each with a disclosure arrow:

- ▶ Heterogeneous instance classes in DB cluster (1)
DB clusters which have heterogeneous instance types [Info](#)
- ▶ Heterogeneous parameters for DB cluster (1)
DB clusters which have heterogeneous parameter groups assigned to its instances [Info](#)

3. On the **Recommendations** page, choose one of the following:
 - **Active** – Shows the current recommendations that you can apply, dismiss, or schedule.
 - **Dismissed** – Shows the recommendations that have been dismissed. When you choose **Dismissed**, you can apply these dismissed recommendations.
 - **Scheduled** – Shows the recommendations that are scheduled but not yet applied. These recommendations will be applied in the next scheduled maintenance window.
 - **Applied** – Shows the recommendations that are currently applied.

From any list of recommendations, you can open a section to view the recommendations in that section.

Recommendations

Active (2) Dismissed (0) Scheduled (0) Applied (0)

▼ Heterogeneous instance classes in DB cluster (1)
DB clusters which have heterogeneous instance types [Info](#)

DB clusters

Dismiss Schedule Apply now

Resource	Recommendation	Affected resources
cluster-1	Your DB cluster cluster-1 has DB instances that use different DB instance classes. Using different DB instance classes for DB instances can cause problems. To avoid problems and for easier maintenance, we recommend using db.t3.small for all of the DB instances in the DB cluster.	cluster-1-reader

▶ Heterogeneous parameters for DB cluster (1)
DB clusters which have heterogeneous parameter groups assigned to its instances [Info](#)

To configure preferences for displaying recommendations in each section, choose the **Preferences** icon.

Recommendations

Active (2) Dismissed (0) Scheduled (0) Applied (0)

▼ Heterogeneous instance classes in DB cluster (1)
DB clusters which have heterogeneous instance types [Info](#)

DB clusters

Dismiss Schedule Apply now

Resource	Recommendation	Affected resources
cluster-1	Your DB cluster cluster-1 has DB instances that use different DB instance classes. Using different DB instance classes for DB instances can cause problems. To avoid problems and for easier maintenance, we recommend using db.t3.small for all of the DB instances in the DB cluster.	cluster-1-reader

▶ Heterogeneous parameters for DB cluster (1)
DB clusters which have heterogeneous parameter groups assigned to its instances [Info](#)

From the **Preferences** window that appears, you can set display options. These options include the visible columns and the number of recommendations to display on the page.

4. Manage your active recommendations:

- Choose **Active** and open one or more sections to view the recommendations in them.
- Choose one or more recommendations and choose **Apply now** (to apply them immediately), **Schedule** (to apply them in next maintenance window), or **Dismiss**.

If the **Apply now** button appears for a recommendation but is unavailable (grayed out), the DB instance is not available. You can apply recommendations immediately only if the DB instance status is **available**. For example, you can't apply recommendations immediately to the DB

instance if its status is **modifying**. In this case, wait for the DB instance to be available and then apply the recommendation.

If the **Apply now** button doesn't appear for a recommendation, you can't apply the recommendation using the **Recommendations** page. You can modify the DB instance to apply the recommendation manually.

For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

Note

When you choose **Apply now**, a brief DB instance outage might result.

Viewing metrics in the Amazon RDS console

Amazon RDS integrates with Amazon CloudWatch to display a variety of Aurora DB cluster metrics in the RDS console. Some metrics are apply at the cluster level, whereas others apply at the instance level. For descriptions of the instance-level and cluster-level metrics, see [Metrics reference for Amazon Aurora \(p. 633\)](#).

The **Monitoring** tab for your Aurora DB cluster shows the following categories of metrics:

- **CloudWatch** – Shows the Amazon CloudWatch metrics for Aurora that you can access in the RDS console. You can also access these metrics in the CloudWatch console. Each metric includes a graph that shows the metric monitored over a specific time span. For a list of CloudWatch metrics, see [Amazon CloudWatch metrics for Amazon Aurora \(p. 633\)](#).
- **Enhanced monitoring** – Shows a summary of operating-system metrics when your Aurora DB cluster has turned on Enhanced Monitoring. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. Each OS metric includes a graph showing the metric monitored over a specific time span. For an overview, see [Monitoring OS metrics with Enhanced Monitoring \(p. 626\)](#). For a list of Enhanced Monitoring metrics, see [OS metrics in Enhanced Monitoring \(p. 660\)](#).
- **OS Process list** – Shows details for each process running in your DB cluster.
- **Performance Insights** – Opens the Amazon RDS Performance Insights dashboard for a DB instance in your Aurora DB cluster. Performance Insights isn't supported at the cluster level. For an overview of Performance Insights, see [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 573\)](#). For a list of Performance Insights metrics, see [Amazon CloudWatch metrics for Performance Insights \(p. 652\)](#).

To view metrics for your Aurora DB cluster in the RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the Aurora DB cluster that you want to monitor.

The database page appears. The following example shows an Amazon Aurora PostgreSQL database named `apga`.

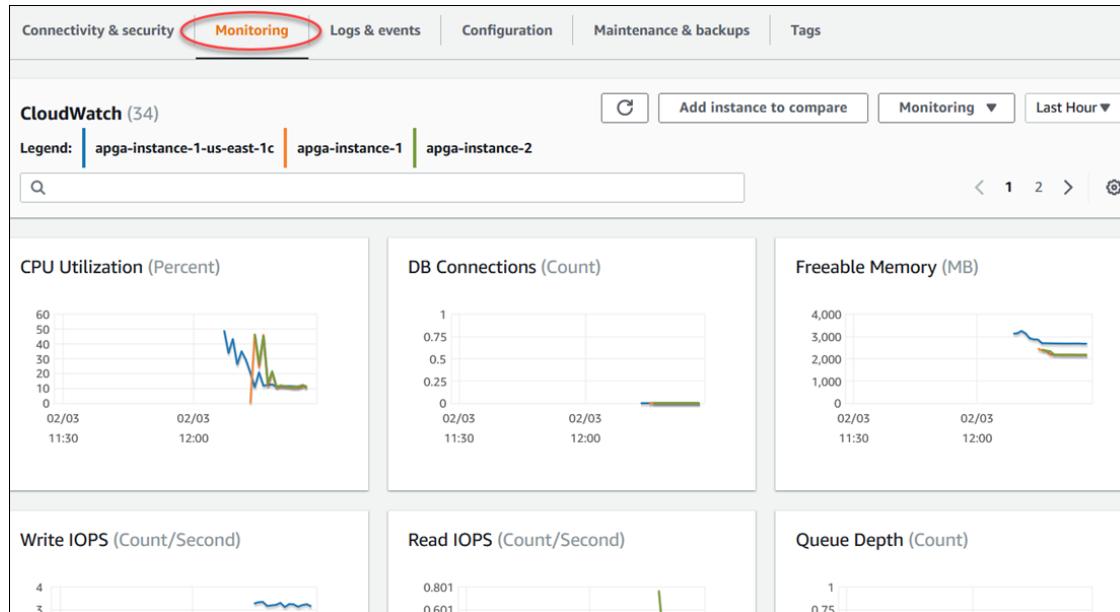

The screenshot shows the 'Databases' section of the Amazon RDS console for the 'apga' cluster. The main table lists the following database instances:

DB identifier	DB cluster identifier	Role	Engine
apga	apga	Regional cluster	Aurora PostgreSQL
apga-instance-1-us-east-1c	apga	Writer instance	Aurora PostgreSQL
apga-instance-1	apga	Reader instance	Aurora PostgreSQL
apga-instance-2	apga	Reader instance	Aurora PostgreSQL

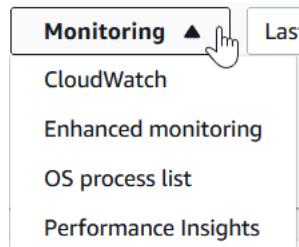

Below the table, there are tabs for **Connectivity & security**, **Monitoring**, **Logs & events**, **Configuration**, **Maintenance & backups**, and **Tags**. The **Monitoring** tab is highlighted in orange.

4. Scroll down and choose **Monitoring**.

The monitoring section appears. By default, CloudWatch metrics are shown. For descriptions of these metrics, see [Amazon CloudWatch metrics for Amazon Aurora \(p. 633\)](#).

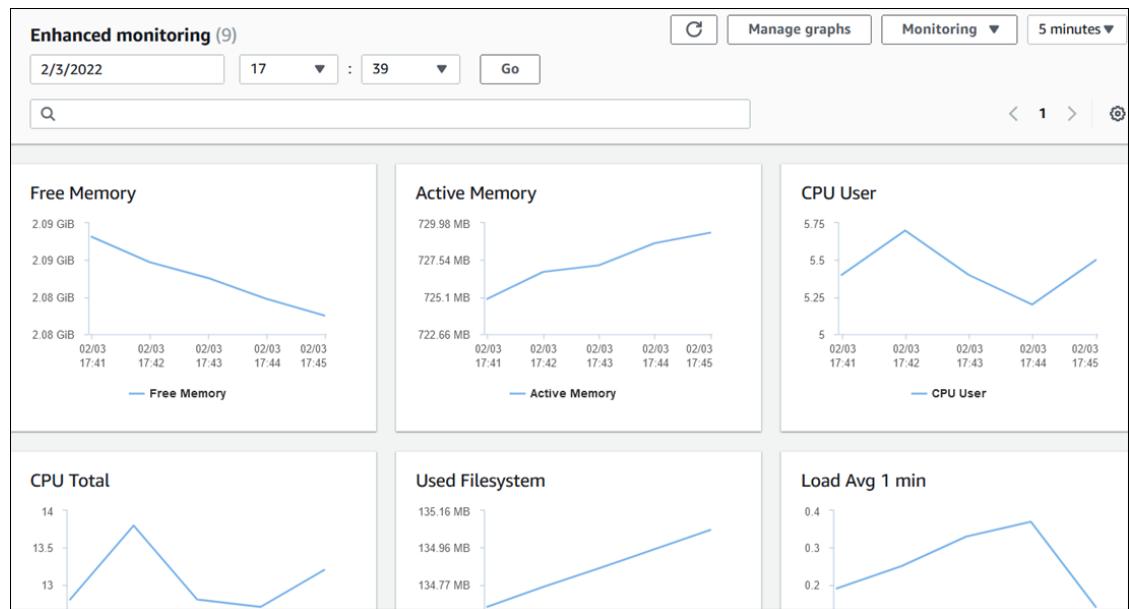

5. Choose **Monitoring** to see the metric categories.

6. Choose the category of metrics that you want to see.

The following example shows Enhanced Monitoring metrics. For descriptions of these metrics, see [OS metrics in Enhanced Monitoring \(p. 660\)](#).

Tip

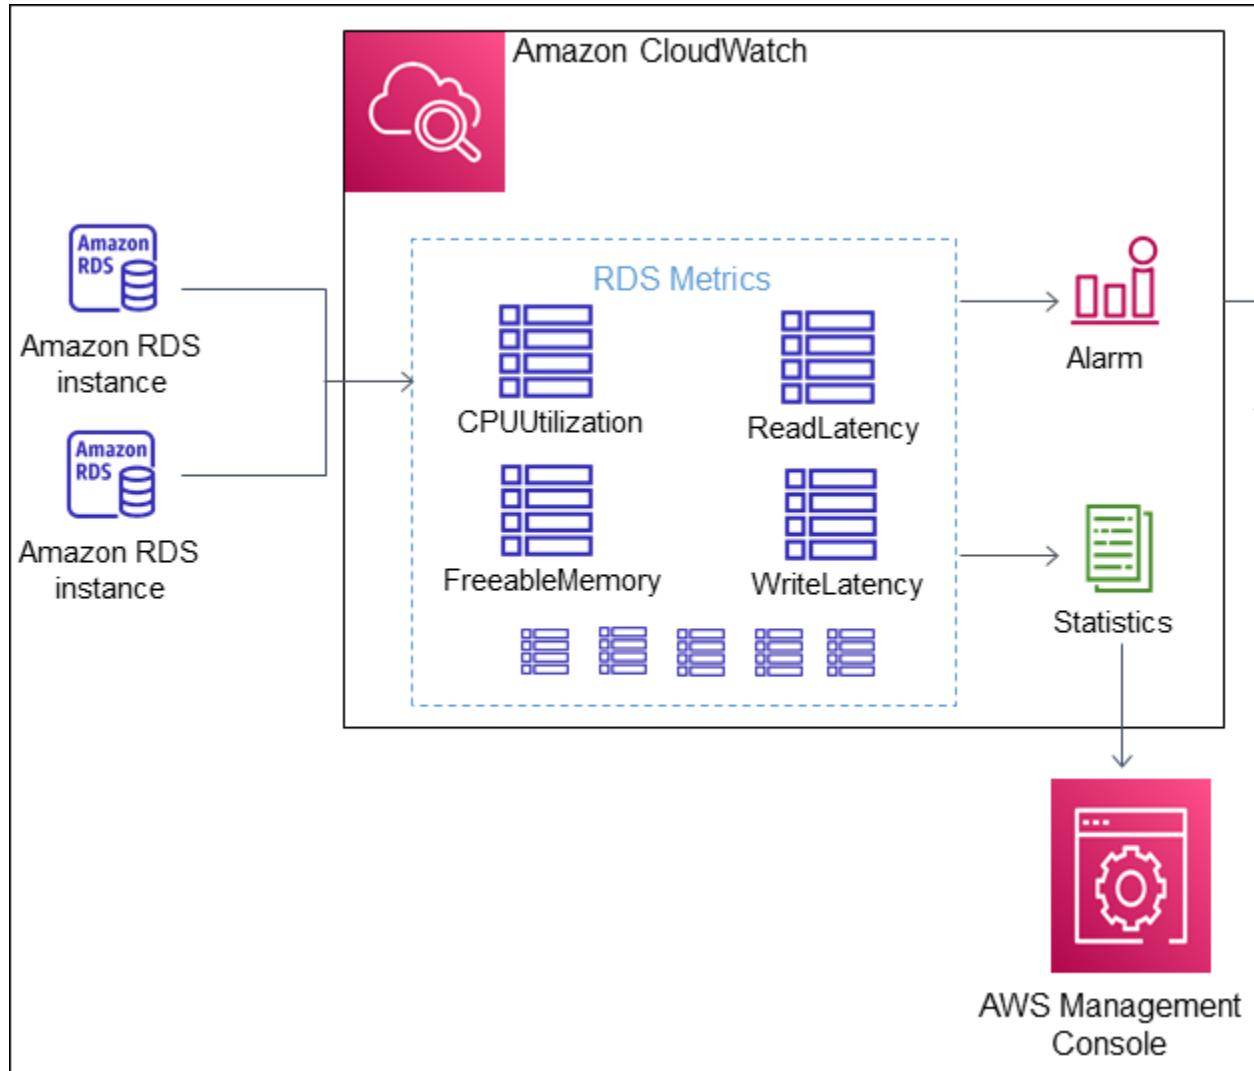

To choose the time range of the metrics represented by the graphs, you can use the time range list.

To bring up a more detailed view, you can choose any graph. You can also apply metric-specific filters to the data.

Monitoring Amazon Aurora metrics with Amazon CloudWatch

Amazon CloudWatch is a metrics repository. The repository collects and processes raw data from Amazon Aurora into readable, near real-time metrics. For a complete list of Amazon Aurora metrics sent to CloudWatch, see [Amazon RDS dimensions and metrics](#) in the *Amazon CloudWatch User Guide*.

By default, Amazon Aurora automatically sends metric data to CloudWatch in 1-minute periods. Data points with a period of 60 seconds (1 minute) are available for 15 days. This means that you can access historical information and see how your web application or service is performing.

For more information about CloudWatch, see [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*. For more information about CloudWatch metrics retention, see [Metrics retention](#).

Note

If you are using Amazon RDS Performance Insights, additional metrics are available. For more information, see [Amazon CloudWatch metrics for Performance Insights \(p. 652\)](#).

Topics

- [Viewing DB instance metrics in the CloudWatch console and CLI \(p. 568\)](#)
- [Creating CloudWatch alarms to monitor Amazon Aurora \(p. 571\)](#)

Viewing DB instance metrics in the CloudWatch console and CLI

Following, you can find details about how to view metrics for your DB instance using CloudWatch. For information on monitoring metrics for your DB instance's operating system in real time using CloudWatch Logs, see [Monitoring OS metrics with Enhanced Monitoring \(p. 626\)](#).

When you use Amazon Aurora resources, Amazon Aurora sends metrics and dimensions to Amazon CloudWatch every minute. You can use the following procedures to view the metrics for Amazon Aurora in the CloudWatch console and CLI.

Console

To view metrics using the Amazon CloudWatch console

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. If necessary, change the AWS Region. From the navigation bar, choose the AWS Region where your AWS resources are. For more information, see [Regions and endpoints](#).
3. In the navigation pane, choose **Metrics** and then **All metrics**.

The screenshot shows the CloudWatch Metrics console interface. At the top, there are tabs: 'Browse' (highlighted in orange), 'Query', 'Graphed metrics', 'Options', and 'Source'. To the right of these are buttons for 'Add math ▾' and 'Graph with SQL'. Below the tabs, the title 'Metrics (1301)' is followed by a 'Info' link. A dropdown menu shows 'N. Virginia ▾' and a search bar with placeholder text 'Search for any metric, dimension or resource id'. The main area displays a grid of service namespaces and their metric counts:

EBS	9	EC2	17	Events
Lambda	26	Logs	35	RDS
S3	8	SSM Run Command	3	Usage

A red circle highlights the 'RDS' namespace in the third row. To the right of the grid, there are additional buttons for 'Graph with SQL' and 'Graph'.

4. Scroll down and choose the **RDS** metric namespace.

The page displays the Amazon Aurora dimensions. For descriptions of these dimensions, see [Amazon CloudWatch dimensions for Aurora \(p. 649\)](#).

The screenshot shows the CloudWatch Metrics console with the 'Metrics' tab selected. The top navigation bar includes 'Browse', 'Query', 'Graphed metrics', 'Options', 'Source', 'Add math ▾', and 'Graph with SQL'. A search bar at the top right says 'Search for any metric, dimension or resource id'. Below the navigation is a breadcrumb trail: 'N. Virginia ▾ > All > RDS'. The main area displays several metric categories with counts: 'DBClusterIdentifier, Role' (153), 'DbClusterIdentifier, EngineName' (6), 'DBClusterIdentifier' (114), 'Per-Database Metrics' (332), 'By Database Class' (191), and 'By Database Engine' (191). A large 'Across All Databases' box shows a count of 114.

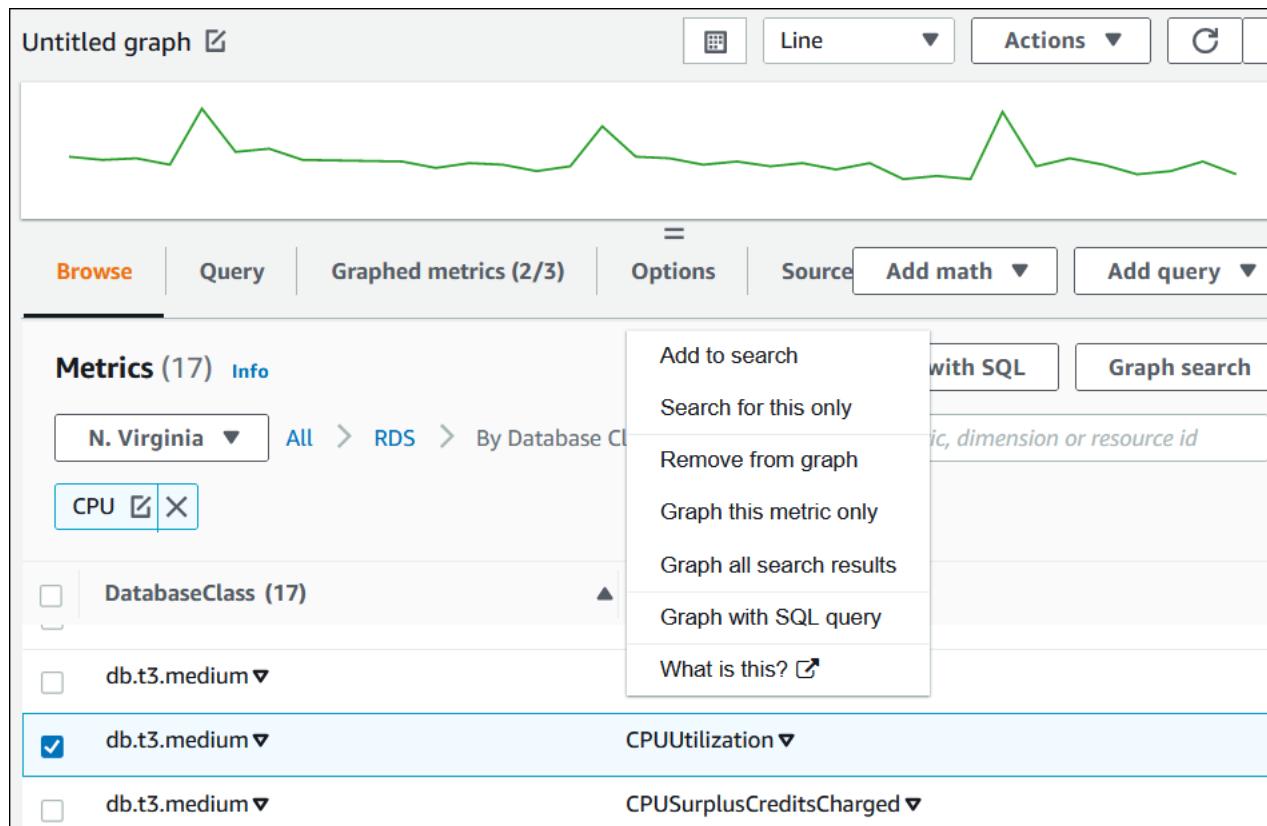

- Choose a metric dimension, for example **By Database Class**.

The screenshot shows the CloudWatch Metrics console with the 'Metrics' tab selected. The top navigation bar includes 'Browse', 'Query', 'Graphed metrics (1)', 'Options', 'Source', 'Add math ▾', and 'Add query ▾'. A search bar at the top right says 'Search for any metric, dimension or resource id'. Below the navigation is a breadcrumb trail: 'N. Virginia ▾ > All > RDS > By Database Class'. The main area lists metrics under 'DatabaseClass (191)'. Each item has a checkbox on the left and a dropdown arrow on the right. The columns are labeled 'Metric name' and 'Dimension'. The listed metrics are: AbortedClients, ActiveTransactions, and Aurora_pq_request_attempted, all associated with the db.r6g.large dimension.

- Do any of the following actions:

- To sort the metrics, use the column heading.
- To graph a metric, select the check box next to the metric.
- To filter by resource, choose the resource ID, and then choose **Add to search**.
- To filter by metric, choose the metric name, and then choose **Add to search**.

The following example filters on the **db.t3.medium** class and graphs the **CPUUtilization** metric.

AWS CLI

To obtain metric information by using the AWS CLI, use the CloudWatch command [list-metrics](#). In the following example, you list all metrics in the AWS/RDS namespace.

```
aws cloudwatch list-metrics --namespace AWS/RDS
```

To obtain metric statistics, use the command [get-metric-statistics](#). The following command gets CPUUtilization statistics for instance `my-instance` over the specific 24-hour period, with a 5-minute granularity.

Example

For Linux, macOS, or Unix:

```
aws cloudwatch get-metric-statistics --namespace AWS/RDS \
--metric-name CPUUtilization \
--start-time 2021-12-15T00:00:00Z \
--end-time 2021-12-16T00:00:00Z \
--period 360 \
--statistics Minimum \
--dimensions Name=DBInstanceIdentifier,Value=my-instance
```

For Windows:

```
aws cloudwatch get-metric-statistics --namespace AWS/RDS ^
--metric-name CPUUtilization ^
```

```
--start-time 2021-12-15T00:00:00Z ^
--end-time 2021-12-16T00:00:00Z ^
--period 360 ^
--statistics Minimum ^
--dimensions Name=DBInstanceIdentifier,Value=my-instance
```

Sample output appears as follows:

```
{
    "Datapoints": [
        {
            "Timestamp": "2021-12-15T18:00:00Z",
            "Minimum": 8.7,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2021-12-15T23:54:00Z",
            "Minimum": 8.12486458559024,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2021-12-15T17:24:00Z",
            "Minimum": 8.841666666666667,
            "Unit": "Percent"
        },
        ...
        {
            "Timestamp": "2021-12-15T22:48:00Z",
            "Minimum": 8.366248354248954,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

For more information, see [Getting statistics for a metric](#) in the *Amazon CloudWatch User Guide*.

Creating CloudWatch alarms to monitor Amazon Aurora

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period that you specify. The alarm can also perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state. The state must have changed and have been maintained for a specified number of time periods. The following procedures show how to create alarms for Amazon RDS.

Note

For Aurora, use WRITER or READER role metrics to set up alarms instead of relying on metrics for specific DB instances. Aurora DB instance roles can change roles over time. You can find these role-based metrics in the CloudWatch console.

Aurora Auto Scaling automatically sets alarms based on READER role metrics. For more information about Aurora Auto Scaling, see [Using Amazon Aurora Auto Scaling with Aurora replicas \(p. 427\)](#).

To set alarms using the CloudWatch console

1. Sign in to the AWS Management Console and open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.

2. Choose **Alarms** and then choose **Create Alarm**. Doing this launches the Create Alarm Wizard.
3. Choose **RDS Metrics** and scroll through the Amazon RDS metrics to find the metric that you want to place an alarm on. To display just Amazon RDS metrics, search for the identifier of your resource. Choose the metric to create an alarm on and then choose **Next**.
4. Enter **Name**, **Description**, and **Whenever** values for the metric.
5. If you want CloudWatch to send you an email when the alarm state is reached, for **Whenever this alarm**, choose **State is ALARM**. For **Send notification to**, choose an existing SNS topic. If you choose **Create topic**, you can set the name and email addresses for a new email subscription list. This list is saved and appears in the field for future alarms.

Note

If you use **Create topic** to create a new Amazon SNS topic, the email addresses must be verified before they receive notifications. Emails are only sent when the alarm enters an alarm state. If this alarm state change happens before the email addresses are verified, the addresses don't receive a notification.

6. Preview the alarm that you're about to create in the **Alarm Preview** area, and then choose **Create Alarm**.

To set an alarm using the AWS CLI

- Call [put-metric-alarm](#). For more information, see [AWS CLI Command Reference](#).

To set an alarm using the CloudWatch API

- Call [PutMetricAlarm](#). For more information, see [Amazon CloudWatch API Reference](#)

Monitoring DB load with Performance Insights on Amazon Aurora

Performance Insights expands on existing Amazon Aurora monitoring features to illustrate your cluster performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users.

Topics

- [Overview of Performance Insights \(p. 573\)](#)
- [Enabling and disabling Performance Insights \(p. 577\)](#)
- [Enabling the Performance Schema for Performance Insights on Aurora MySQL \(p. 580\)](#)
- [Configuring access policies for Performance Insights \(p. 582\)](#)
- [Analyzing metrics with the Performance Insights dashboard \(p. 585\)](#)
- [Retrieving metrics with the Performance Insights API \(p. 607\)](#)
- [Logging Performance Insights calls using AWS CloudTrail \(p. 621\)](#)

Overview of Performance Insights

By default, Performance Insights is enabled in the console create wizard for Amazon RDS engines. If you have more than one database on a DB instance, Performance Insights aggregates performance data.

You can find an overview of Performance Insights in the following video.

[Using Performance Insights to Analyze Performance of Amazon Aurora PostgreSQL](#)

Topics

- [Database load \(p. 573\)](#)
- [Maximum CPU \(p. 576\)](#)
- [Amazon Aurora DB engine support for Performance Insights \(p. 576\)](#)
- [AWS Region support for Performance Insights \(p. 577\)](#)
- [Cost of Performance Insights \(p. 577\)](#)

Database load

Database load (DB load) measures the level of activity in your database. The key metric in Performance Insights is `DBLoad`, which is collected every second.

Topics

- [Active sessions \(p. 573\)](#)
- [Average active sessions \(p. 574\)](#)
- [Average active executions \(p. 574\)](#)
- [Dimensions \(p. 575\)](#)

Active sessions

A *database session* represents an application's dialogue with a relational database. An *active session* is a connection that has submitted work to the DB engine and is waiting for a response.

A session is active when it's either running on CPU or waiting for a resource to become available so that it can proceed. For example, an active session might wait for a page to be read into memory, and then consume CPU while it reads data from the page.

Average active sessions

The *average active sessions (AAS)* is the unit for the `DBLoad` metric in Performance Insights. To get the average active sessions, Performance Insights samples the number of sessions concurrently running a query. The AAS is the total number of sessions divided by the total number of samples for a specific time period. The following table shows 5 consecutive samples of a running query.

Sample	Number of sessions running query	AAS	Calculation
1	2	2	2 sessions / 1 sample
2	0	1	2 sessions / 2 samples
3	4	2	6 sessions / 3 samples
4	0	1.5	6 sessions / 4 samples
5	4	2	10 sessions / 5 samples

In the preceding example, the DB load for the time interval was 2 AAS. This measurement means that, on average, 2 sessions were active at a time during the time period when the 5 samples were taken.

An analogy for DB load is activity in a warehouse. Suppose that the warehouse employs 100 workers. If 1 order comes in, 1 worker fulfills the order while the other workers are idle. If 100 orders come in, all 100 workers fulfill orders simultaneously. If you periodically sample how many workers are active over a given time period, you can calculate the average number of active workers. The calculation shows that, on average, N workers are busy fulfilling orders at any given time. If the average was 50 workers yesterday and 75 workers today, the activity level in the warehouse increased. In the same way, DB load increases as session activity increases.

Average active executions

The *average active executions (AAE)* per second is related to AAS. To calculate the AAE, Performance Insights divides the total execution time of a query by the time interval. The following table shows the AAE calculation for the same query in the preceding table.

Elapsed time (sec)	Total execution time (sec)	AAE	Calculation
60	120	2	120 execution seconds/60 elapsed seconds
120	120	1	120 execution seconds/120 elapsed seconds
180	380	2.11	380 execution seconds/180 elapsed seconds
240	380	1.58	380 execution seconds/240 elapsed seconds

Elapsed time (sec)	Total execution time (sec)	AAE	Calculation
300	600	2	600 execution seconds/300 elapsed seconds

In most cases, the AAS and AAE for a query are approximately the same. However, because the inputs to the calculations are different data sources, the calculations often vary slightly.

Dimensions

The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called *dimensions*. You can think of dimensions as "slice by" categories for the different characteristics of the DBLoad metric.

When you are diagnosing performance issues, the following dimensions are often the most useful:

Topics

- [Wait events \(p. 575\)](#)
- [Top SQL \(p. 576\)](#)

For a complete list of dimensions for the Aurora engines, see [DB load sliced by dimensions \(p. 588\)](#).

Wait events

A *wait event* causes a SQL statement to wait for a specific event to happen before it can continue running. Wait events are an important dimension, or category, for DB load because they indicate where work is impeded.

Every active session is either running on the CPU or waiting. For example, sessions consume CPU when they search memory for a buffer, perform a calculation, or run procedural code. When sessions aren't consuming CPU, they might be waiting for a memory buffer to become free, a data file to be read, or a log to be written to. The more time that a session waits for resources, the less time it runs on the CPU.

When you tune a database, you often try to find out the resources that sessions are waiting for. For example, two or three wait events might account for 90 percent of DB load. This measure means that, on average, active sessions are spending most of their time waiting for a small number of resources. If you can find out the cause of these waits, you can attempt a solution.

Consider the analogy of a warehouse worker. An order comes in for a book. The worker might be delayed in fulfilling the order. For example, a different worker might be currently restocking the shelves, a trolley might not be available. Or the system used to enter the order status might be slow. The longer the worker waits, the longer it takes to fulfill the order. Waiting is a natural part of the warehouse workflow, but if wait time becomes excessive, productivity decreases. In the same way, repeated or lengthy session waits can degrade database performance. For more information, see [Tuning with wait events for Aurora PostgreSQL](#) and [Tuning with wait events for Aurora MySQL](#) in the *Amazon Aurora User Guide*.

Wait events vary by DB engine:

- For a list of the common wait events for Aurora MySQL, see [Aurora MySQL wait events \(p. 1063\)](#). To learn how to tune using these wait events, see [Tuning Aurora MySQL with wait events and thread states \(p. 837\)](#).
- For information about all MySQL wait events, see [Wait Event Summary Tables](#) in the MySQL documentation.

- For a list of common wait events for Aurora PostgreSQL, see [Amazon Aurora PostgreSQL wait events \(p. 1570\)](#). To learn how to tune using these wait events, see [Tuning with wait events for Aurora PostgreSQL \(p. 1376\)](#).
- For information about all PostgreSQL wait events, see [PostgreSQL Wait Events](#) in the PostgreSQL documentation.

Top SQL

Where wait events show bottlenecks, top SQL shows which queries are contributing the most to DB load. For example, many queries might be currently running on the database, but a single query might consume 99 percent of the DB load. In this case, the high load might indicate a problem with the query.

By default, the Performance Insights console displays top SQL queries that are contributing to the database load. The console also shows relevant statistics for each statement. To diagnose performance problems for a specific statement, you can examine its execution plan.

Maximum CPU

In the dashboard, the **Database load** chart collects, aggregates, and displays session information. To see whether active sessions are exceeding the maximum CPU, look at their relationship to the **Max vCPU** line. The **Max vCPU** value is determined by the number of vCPU (virtual CPU) cores for your DB instance. For Aurora Serverless v2, **Max vCPU** represents the estimated number of vCPUs.

If the DB load is often above the **Max vCPU** line, and the primary wait state is CPU, the CPU is overloaded. In this case, you might want to throttle connections to the instance, tune any SQL queries with a high CPU load, or consider a larger instance class. High and consistent instances of any wait state indicate that there might be bottlenecks or resource contention issues to resolve. This can be true even if the DB load doesn't cross the **Max vCPU** line.

Amazon Aurora DB engine support for Performance Insights

Following, you can find the Amazon Aurora DB engines that support Performance Insights.

Amazon Aurora DB engine	Supported engine versions when parallel query isn't turned on	Supported engine versions when parallel query is turned on	Instance class restrictions
Amazon Aurora MySQL-Compatible Edition	<p>Performance Insights is supported for the following engine versions:</p> <ul style="list-style-type: none"> 3.0 and higher 3 versions (compatible with MySQL 8.0) 2.04.2 and higher 2 versions (compatible with MySQL 5.7) 1.17.3 and higher 1 versions (compatible with MySQL 5.6) 	<p>Performance Insights with parallel query enabled is supported for the following engine versions:</p> <ul style="list-style-type: none"> 2.09.0 and higher 2 versions (compatible with MySQL 5.7) 1.23.0 and higher 1 versions (compatible with MySQL 5.6) 	<p>Performance Insights has the following engine class restrictions:</p> <ul style="list-style-type: none"> db.t2 – Not supported db.t3 – Not supported db.t4g – Supported only for 2.10.1 and higher 2 versions (compatible with MySQL 5.7)
Amazon Aurora PostgreSQL-	Performance Insights is supported for all engine versions.	N/A	N/A

Amazon Aurora DB engine	Supported engine versions when parallel query isn't turned on	Supported engine versions when parallel query is turned on	Instance class restrictions
Compatible Edition			

Note

Aurora Serverless doesn't support Performance Insights.

AWS Region support for Performance Insights

Performance Insights for Amazon Aurora is supported for all AWS Regions except the following:

- AWS GovCloud (US-East)
- AWS GovCloud (US-West)
- Asia Pacific (Jakarta)

Cost of Performance Insights

For cost information, see [Performance Insights Pricing](#).

Enabling and disabling Performance Insights

To use Performance Insights, enable it on your DB instance. If needed, you can disable it later. Enabling and disabling Performance Insights doesn't cause downtime, a reboot, or a failover.

Note

Performance Schema is an optional performance tool used by Aurora MySQL. If you turn Performance Schema on or off, you need to reboot. If you turn Performance Insights on or off, however, you don't need to reboot. For more information, see [Enabling the Performance Schema for Performance Insights on Aurora MySQL \(p. 580\)](#).

If you use Performance Insights together with Aurora Global Database, enable Performance Insights individually for the DB instances in each AWS Region. For details, see [Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights \(p. 277\)](#).

The Performance Insights agent consumes limited CPU and memory on the DB host. When the DB load is high, the agent limits the performance impact by collecting data less frequently.

Console

In the console, you can enable or disable Performance Insights when you create or modify a new DB instance.

[Enabling or disabling Performance Insights when creating an instance](#)

When you create a new DB instance, enable Performance Insights by choosing **Enable Performance Insights** in the **Performance Insights** section. Or choose **Disable Performance Insights**.

To create a DB instance, follow the instructions for your DB engine in [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

The following screenshot shows the **Performance Insights** section.

Description	Account	KMS key ID
Default master key that protects my RDS database volumes when no other key is defined	This account ([REDACTED])	[REDACTED]

If you choose **Enable Performance Insights**, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. Choose either 7 days (the default) or 2 years.
- **AWS KMS key** – Specify your AWS KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see [Configuring an AWS KMS policy for Performance Insights \(p. 584\)](#).

Enabling or disabling Performance Insights when modifying an instance

In the console, you can modify a DB instance to enable or disable Performance Insights using the console.

To enable or disable Performance Insights for a DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases**.
3. Choose a DB instance, and choose **Modify**.
4. In the **Performance Insights** section, choose either **Enable Performance Insights** or **Disable Performance Insights**.

If you choose **Enable Performance Insights**, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. Choose either 7 days (the default) or 2 years. If you chose Long Term Retention (2 years) when you enable Performance Insights, All displays 2 years of data. If you chose Default (7 days) instead, All displays only the past week.
 - **AWS KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see [Encrypting Amazon Aurora resources \(p. 1709\)](#).
5. Choose **Continue**.

6. For **Scheduling of Modifications**, choose Apply immediately. If you choose Apply during the next scheduled maintenance window, your instance ignores this setting and enables Performance Insights immediately.
7. Choose **Modify instance**.

AWS CLI

When you use the [create-db-instance](#) AWS CLI command, enable Performance Insights by specifying `--enable-performance-insights`. Or disable Performance Insights by specifying `--no-enable-performance-insights`.

You can also specify these values using the following AWS CLI commands:

- [create-db-instance-read-replica](#)
- [modify-db-instance](#)
- [restore-db-instance-from-s3](#)

The following procedure describes how to enable or disable Performance Insights for a DB instance using the AWS CLI.

To enable or disable Performance Insights for a DB instance using the AWS CLI

- Call the [modify-db-instance](#) AWS CLI command and supply the following values:
 - `--db-instance-identifier` – The name of the DB instance.
 - `--enable-performance-insights` to enable or `--no-enable-performance-insights` to disable

The following example enables Performance Insights for `sample-db-instance`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier sample-db-instance \
    --enable-performance-insights
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier sample-db-instance ^
    --enable-performance-insights
```

When you enable Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the `--performance-insights-retention-period` option. Valid values are 7 (the default) or 731 (2 years).

The following example enables Performance Insights for `sample-db-instance` and specifies that Performance Insights data is retained for two years.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier sample-db-instance \
    --enable-performance-insights \
```

```
--performance-insights-retention-period 731
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier sample-db-instance ^
--enable-performance-insights ^
--performance-insights-retention-period 731
```

RDS API

When you create a new DB instance using the [CreateDBInstance](#) operation Amazon RDS API operation, enable Performance Insights by setting `EnablePerformanceInsights` to `True`. To disable Performance Insights, set `EnablePerformanceInsights` to `False`.

You can also specify the `EnablePerformanceInsights` value using the following API operations:

- [ModifyDBInstance](#)
- [CreateDBInstanceReadReplica](#)
- [RestoreDBInstanceFromS3](#)

When you enable Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the `PerformanceInsightsRetentionPeriod` parameter. Valid values are 7 (the default) or 731 (2 years).

Enabling the Performance Schema for Performance Insights on Aurora MySQL

The Performance Schema is an optional feature for monitoring Aurora MySQL runtime performance at a low level. You can use Performance insights with or without the Performance Schema. The Performance Schema is designed to have minimal impact on database performance.

Topics

- [Overview of the Performance Schema \(p. 580\)](#)
- [Options for enabling Performance Schema \(p. 581\)](#)
- [Configuring the Performance Schema for automatic management \(p. 581\)](#)

Overview of the Performance Schema

The Performance Schema monitors server events. In this context, an event is a server action that consumes time. Performance Schema events are distinct from binlog events and scheduler events.

The `PERFORMANCE_SCHEMA` storage engine collects event data using instrumentation in the database source code. The engine stores collected events in tables in the `performance_schema` database. You can query `performance_schema` just as you can query any other tables. For more information, see [MySQL Performance Schema](#) in [MySQL Reference Manual](#).

When the Performance Schema is enabled for Aurora MySQL, Performance Insights uses it to provide more detailed information. For example, Performance Insights displays DB load categorized by detailed wait events. You can use wait events to identify bottlenecks. Without the Performance Schema, Performance Insights reports user states such as inserting and sending, which don't help you identify bottlenecks.

Options for enabling Performance Schema

You have the following options for enabling the Performance Schema:

- Allow Performance Insights to manage required Performance Schema parameters automatically.

When you create an Aurora MySQL DB instance with Performance Insights enabled, the Performance Schema is also enabled. In this case, Performance Insights automatically manages your Performance Schema parameters.

For automatic management, the `performance_schema` must be set to 0 and the **Source** must be set to a value other than 0. By default, **Source** is `engine-default`. If you change the `performance_schema` value manually, and then later want to revert to automatic management, see [Configuring the Performance Schema for automatic management \(p. 581\)](#).

Important

When Performance Insights enables the Performance Schema, it doesn't change the parameter group values. However, the values are changed on the instances that are running. The only way to see the changed values is to run the `SHOW GLOBAL VARIABLES` command.

- Set the required Performance Schema parameters yourself.

For Performance Insights to list wait events, set all Performance Schema parameters as shown in the following table.

Parameter Name	Parameter Value
<code>performance_schema</code>	1 (the Source column has the value <code>engine-default</code>)
<code>performance-schema-consumer-events-waits-current</code>	ON
<code>performance-schema-instrument</code>	<code>wait/=%=ON</code>
<code>performance_schema_consumer_global_instrumentation</code>	ON
<code>performance_schema_consumer_thread_instrumentation</code>	ON

Note

If you enable or disable the Performance Schema, you must reboot the database. If you enable or disable Performance Insights, you don't need to reboot the database.

For more information, see [Performance Schema Command Options](#) and [Performance Schema Option and Variable Reference](#) in the MySQL documentation.

Configuring the Performance Schema for automatic management

The following table shows the difference in settings when Performance Insights is and isn't managing the Performance Schema.

Performance Insights isn't managing the Performance Schema	Performance Insights is managing the Performance Schema
<code>performance_schema</code> is 0 or 1	<code>performance_schema</code> is 0

Performance Insights isn't managing the Performance Schema	Performance Insights is managing the Performance Schema
The Source column is set to user	The Source column is set to system

To let Performance Insights manage the Performance Schema automatically

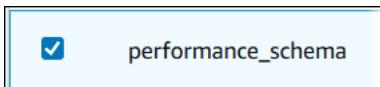

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. Choose **Parameter groups**.

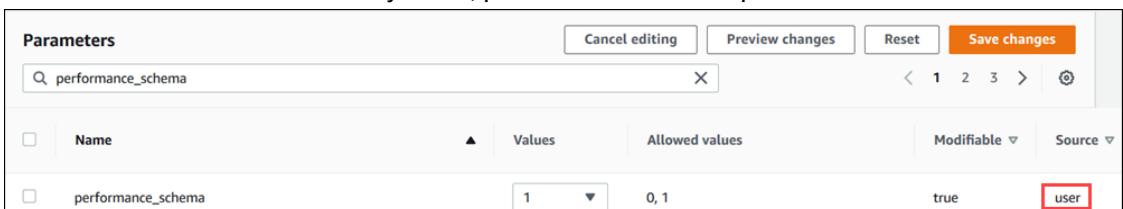

3. Select the name of the parameter group for your DB instance.

4. Enter **performance_schema** in the search bar.

5. Select the **performance_schema** parameter.

6. Check whether **Source** is **system** and **Values** is **0**. If so, Performance Insights is managing the Performance Schema automatically. If not, proceed to the next step.

7. Choose **Edit parameters**.

8. In **Values**, choose **0**.

9. Select **Reset**. When you reset, Aurora MySQL sets **Source** to **system** and **Values** to **0**.

The **Reset parameters in DB parameter group** page appears.

10. Select **Reset parameters**.

11. Restart the DB instance.

Important

Whenever you enable or disable the Performance Schema, you must restart the DB instance.

For more information about modifying instance parameters, see [Modifying parameters in a DB parameter group \(p. 347\)](#). For more information about the dashboard, see [Analyzing metrics with the Performance Insights dashboard \(p. 585\)](#). For more information about the MySQL performance schema, see [MySQL 8.0 Reference Manual](#).

Configuring access policies for Performance Insights

To access Performance Insights, you must have the appropriate permissions from AWS Identity and Access Management (IAM). You have the following options for granting access:

- Attach the `AmazonRDSFullAccess` managed policy to an IAM user or role.
- Create a custom IAM policy and attach it to an IAM user or role.

Also, if you specified a customer managed key when you turned on Performance Insights, make sure that users in your account have the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key.

Attaching the `AmazonRDSFullAccess` policy to an IAM principal

`AmazonRDSFullAccess` is an AWS-managed policy that grants access to all of the Amazon RDS API operations. This policy does the following:

- Grants access to related services used by the Amazon RDS console. For example, this policy grants access to event notifications using Amazon SNS.
- Grants permissions needed for using Performance Insights.

If you attach `AmazonRDSFullAccess` to an IAM user or role, the recipient can use Performance Insights with other console features.

Creating a custom IAM policy for Performance Insights

For users who don't have full access with the `AmazonRDSFullAccess` policy, you can grant access to Performance Insights by creating or modifying a user-managed IAM policy. When you attach the policy to an IAM user or role, the recipient can use Performance Insights.

To create a custom policy

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create Policy** page, choose the JSON tab.
5. Copy and paste the following text, replacing `us-east-1` with the name of your AWS Region and `111122223333` with your customer account number.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "pi:*",  
            "Resource": "arn:aws:pi:us-east-1:111122223333:metrics/rds/*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": "rds:DescribeDBInstances",  
            "Resource": "*"  
        }  
    ]  
}
```

6. Choose **Review policy**.
7. Provide a name for the policy and optionally a description, and then choose **Create policy**.

You can now attach the policy to an IAM user or role. The following procedure assumes that you already have an IAM user available for this purpose.

To attach the policy to an IAM user

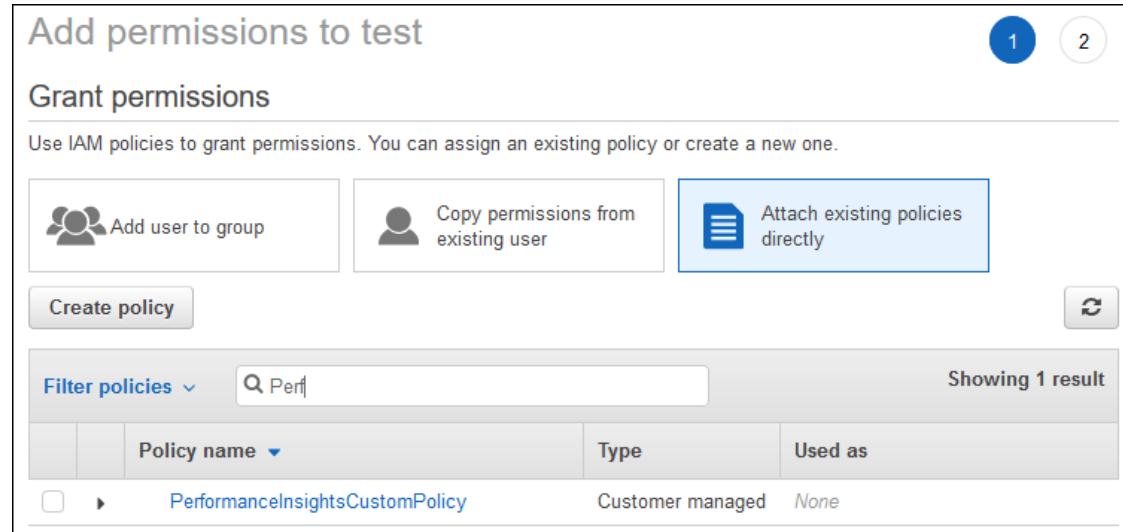

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.

2. In the navigation pane, choose **Users**.
3. Choose an existing user from the list.

Important

To use Performance Insights, make sure that you have access to Amazon RDS in addition to the custom policy. For example, the `AmazonRDSReadOnlyAccess` predefined policy provides read-only access to Amazon RDS. For more information, see [Managing access using policies \(p. 1726\)](#).

4. On the **Summary** page, choose **Add permissions**.
5. Choose **Attach existing policies directly**. For **Search**, type the first few characters of your policy name, as shown following.

6. Choose your policy, and then choose **Next: Review**.
7. Choose **Add permissions**.

Configuring an AWS KMS policy for Performance Insights

Performance Insights uses an AWS KMS key to encrypt sensitive data. When you enable Performance Insights through the API or the console, you have the following options:

- Choose the default AWS managed key.

Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

- Choose a customer managed key.

If you specify a customer managed key, users in your account that call the Performance Insights API need the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key. You can configure these permissions through IAM policies. However, we recommend that you manage these permissions through your KMS key policy. For more information, see [Using key policies in AWS KMS](#).

Example

The following sample key policy shows how to add statements to your KMS key policy. These statements allow access to Performance Insights. Depending on how you use the KMS key, you might want to change some restrictions. Before adding statements to your policy, remove all comments.

```
{  
    "Version" : "2012-10-17",  
    "Id" : "your-policy",  
    "Statement" : [ {  
        //This represents a statement that currently exists in your policy.  
    }  
    ....,  
    //Starting here, add new statement to your policy for Performance Insights.  
    //We recommend that you add one new statement for every RDS instance  
    {  
        "Sid" : "Allow viewing RDS Performance Insights",  
        "Effect": "Allow",  
        "Principal": {  
            "AWS": [  
                //One or more principals allowed to access Performance Insights  
                "arn:aws:iam::444455556666:role/Role1"  
            ]  
        },  
        "Action": [  
            "kms:Decrypt",  
            "kms:GenerateDataKey"  
        ],  
        "Resource": "*",  
        "Condition" : {  
            "StringEquals" : {  
                //Restrict access to only RDS APIs (including Performance Insights).  
                //Replace region with your AWS Region.  
                //For example, specify us-west-2.  
                "kms:ViaService" : "rds.region.amazonaws.com"  
            },  
            "ForAnyValue:StringEquals": {  
                //Restrict access to only data encrypted by Performance Insights.  
                "kms:EncryptionContext:aws:pi:service": "rds",  
                "kms:EncryptionContext:service": "pi",  
  
                //Restrict access to a specific RDS instance.  
                //The value is a DbiResourceId.  
                "kms:EncryptionContext:aws:rds:db-id": "db-AAAAABBBBCCCCDDDDDEEEEE"  
            }  
        }  
    }  
}
```

Analyzing metrics with the Performance Insights dashboard

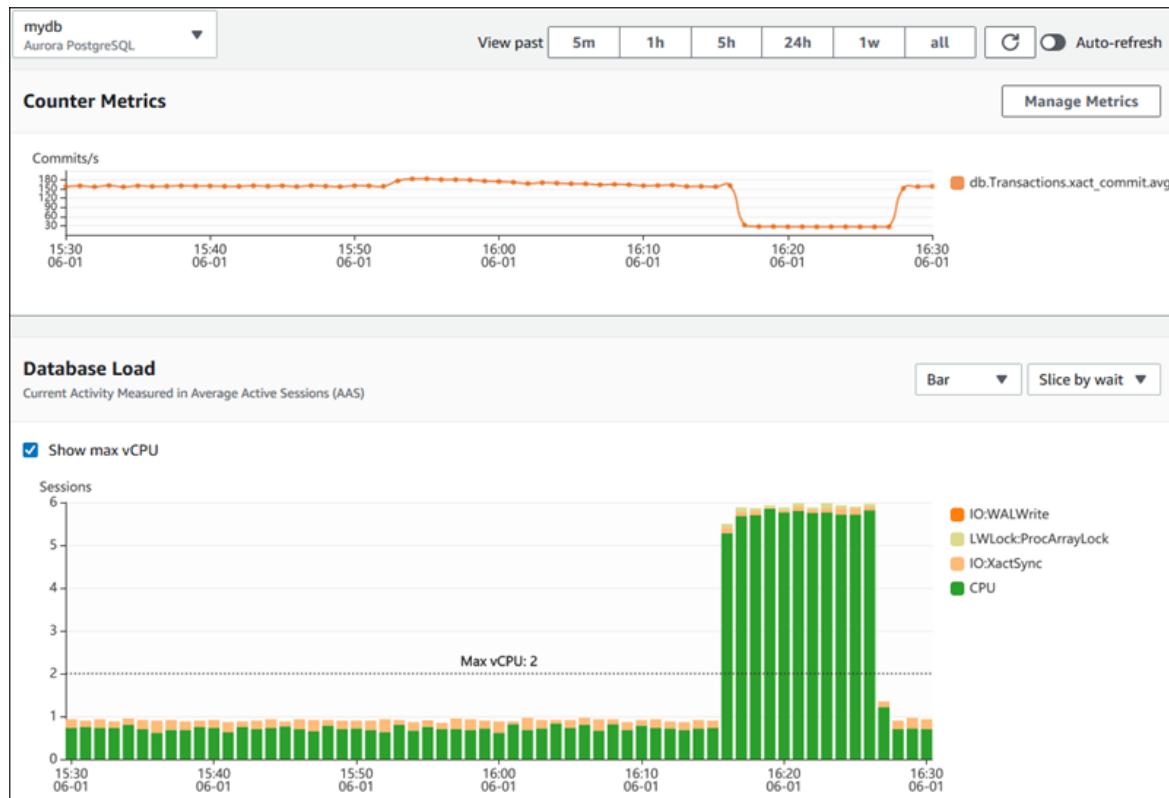

The Performance Insights dashboard contains database performance information to help you analyze and troubleshoot performance issues. On the main dashboard page, you can view information about the database load. You can "slice" DB load by dimensions such as wait events or SQL.

Performance Insights dashboard

- [Overview of the Performance Insights dashboard \(p. 586\)](#)
- [Opening the Performance Insights dashboard \(p. 591\)](#)
- [Analyzing DB load by wait events \(p. 592\)](#)
- [Analyzing running queries using the Performance Insights dashboard \(p. 593\)](#)
- [Accessing the text of SQL statements \(p. 604\)](#)
- [Zooming In on the DB Load chart \(p. 606\)](#)

Overview of the Performance Insights dashboard

The dashboard is the easiest way to interact with Performance Insights. The following example shows the dashboard for a MySQL DB instance. By default, the Performance Insights dashboard shows data for the last hour.

The dashboard is divided into the following parts:

1. **Counter Metrics** – Shows data for specific performance counter metrics.
2. **DB Load Chart** – Shows how the DB load compares to DB instance capacity as represented by the **Max vCPU** line.
3. **Top items** – Shows the top dimensions contributing to DB load.

Topics

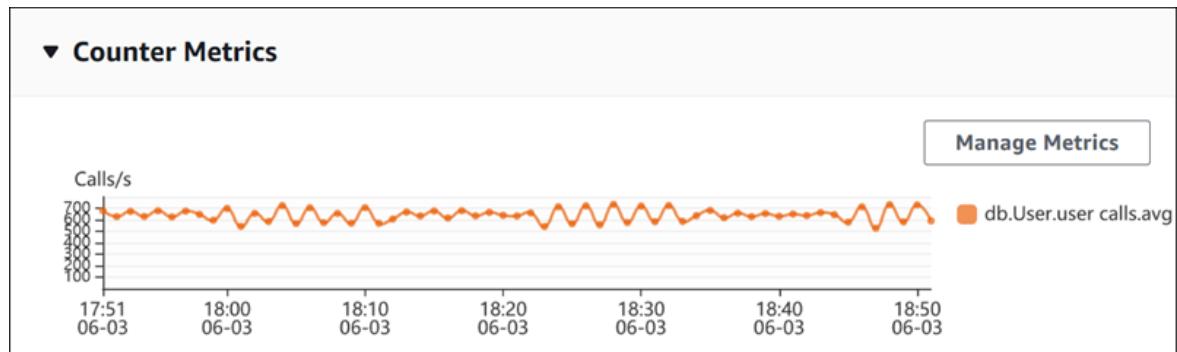

- [Counter metrics chart \(p. 586\)](#)
- [Database load chart \(p. 588\)](#)
- [Top dimensions table \(p. 590\)](#)

Counter metrics chart

With counter metrics, you can customize the Performance Insights dashboard to include up to 10 additional graphs. These graphs show a selection of dozens of operating system and database performance metrics. You can correlate this information with DB load to help identify and analyze performance problems.

The **Counter metrics** chart displays data for performance counters. The default metrics depend on the DB engine:

- Aurora MySQL – db.SQL.Innodb_rows_read.avg
- Aurora PostgreSQL – db.Transactions.xact_commit.avg

To change the performance counters, choose **Manage Metrics**. You can select multiple **OS metrics** or **Database metrics**, as shown in the following screenshot. To see details for any metric, hover over the metric name.

Select metrics shown on the graph

Check the metrics that you want to see on the Performance Insights dashboard.

Find metrics

OS metrics (0) **Database metrics (1)** **Clear all selections**

User

- CPU used by this session
- SQL*Net roundtrips to/from client
- bytes received via SQL*Net from client
- user commits
- logons cumulative
- user calls
- bytes sent via SQL*Net to client
- user rollbacks

Redo

- redo size

Cache

- physical read bytes
- db block gets
- DBWR checkpoints
- physical reads
- consistent gets from cache
- db block gets from cache
- consistent gets

SQL

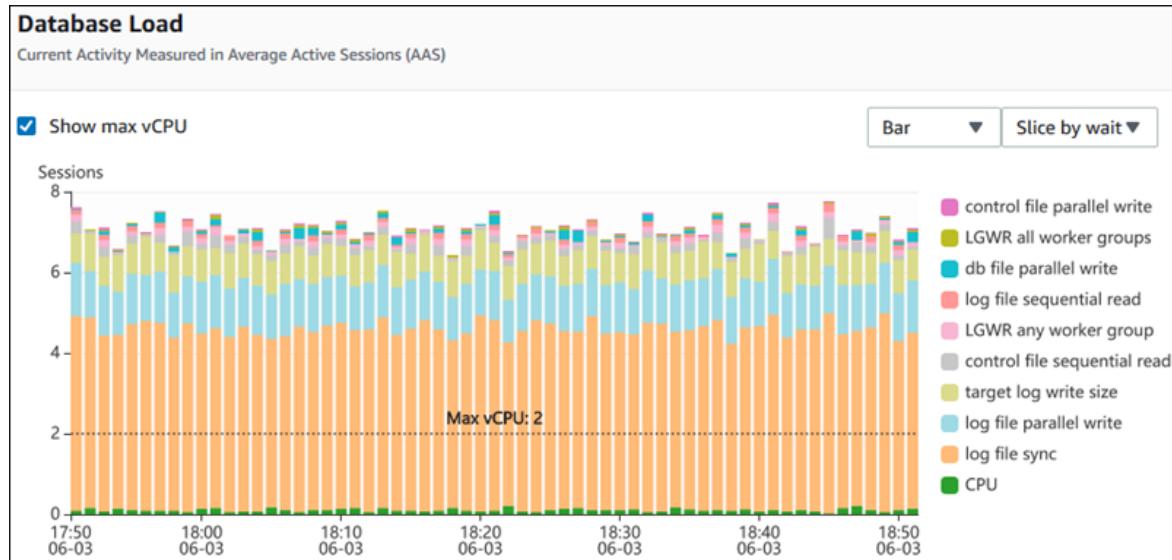

- parse count (total)
- parse count (hard)
- table scan rows gotten
- sorts (memory)
- sorts (disk)
- sorts (rows)

Cancel **Update graph**

For descriptions of the counter metrics that you can add for each DB engine, see [Performance Insights counter metrics \(p. 653\)](#).

Database load chart

The **Database load** chart shows how the database activity compares to DB instance capacity as represented by the **Max vCPU** line. By default, the stacked line chart represents DB load as average active sessions per unit of time. The DB load is sliced (grouped) by wait states.

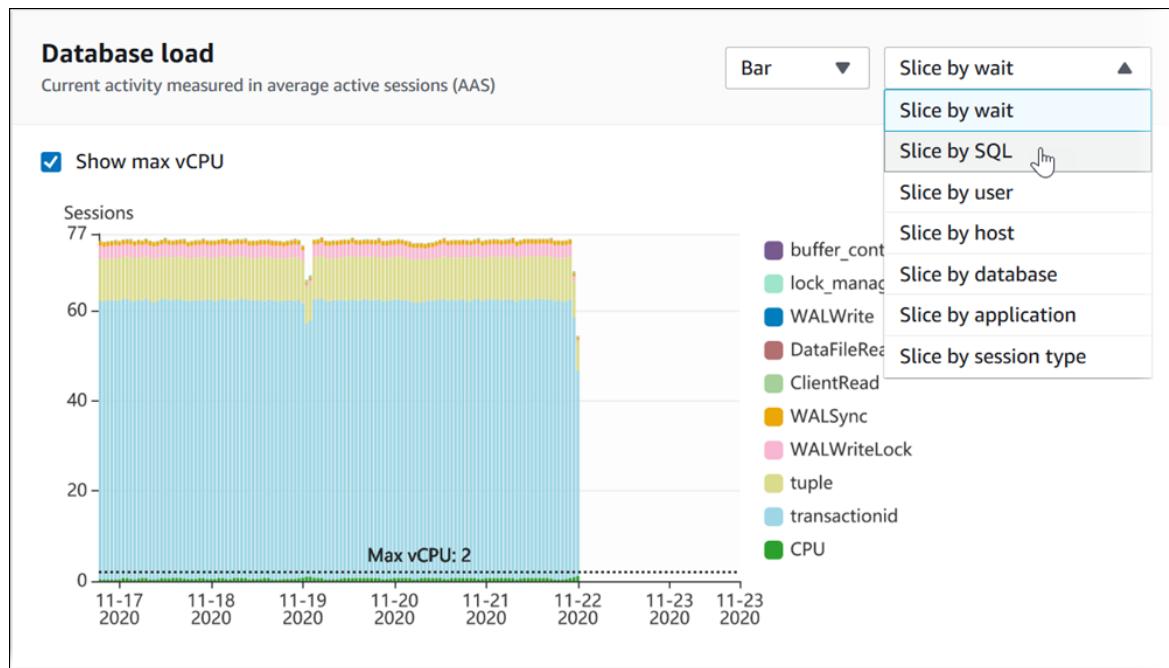

DB load sliced by dimensions

You can choose to display load as active sessions grouped by any supported dimensions. The following table shows which dimensions are supported for the different engines.

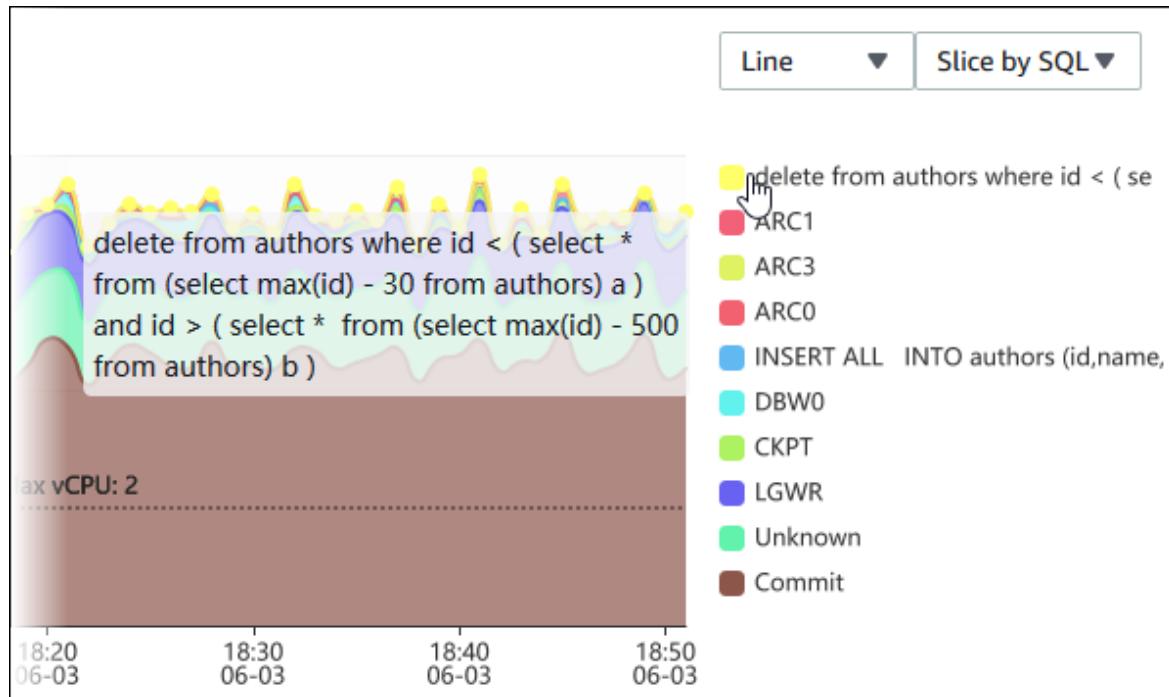

Dimension	Aurora PostgreSQL	Aurora MySQL
Host	Yes	Yes
SQL	Yes	Yes
User	Yes	Yes
Waits	Yes	Yes
Application	Yes	No
Database	Yes	Yes
Session type	Yes	No

The following image shows the dimensions for a PostgreSQL DB instance.

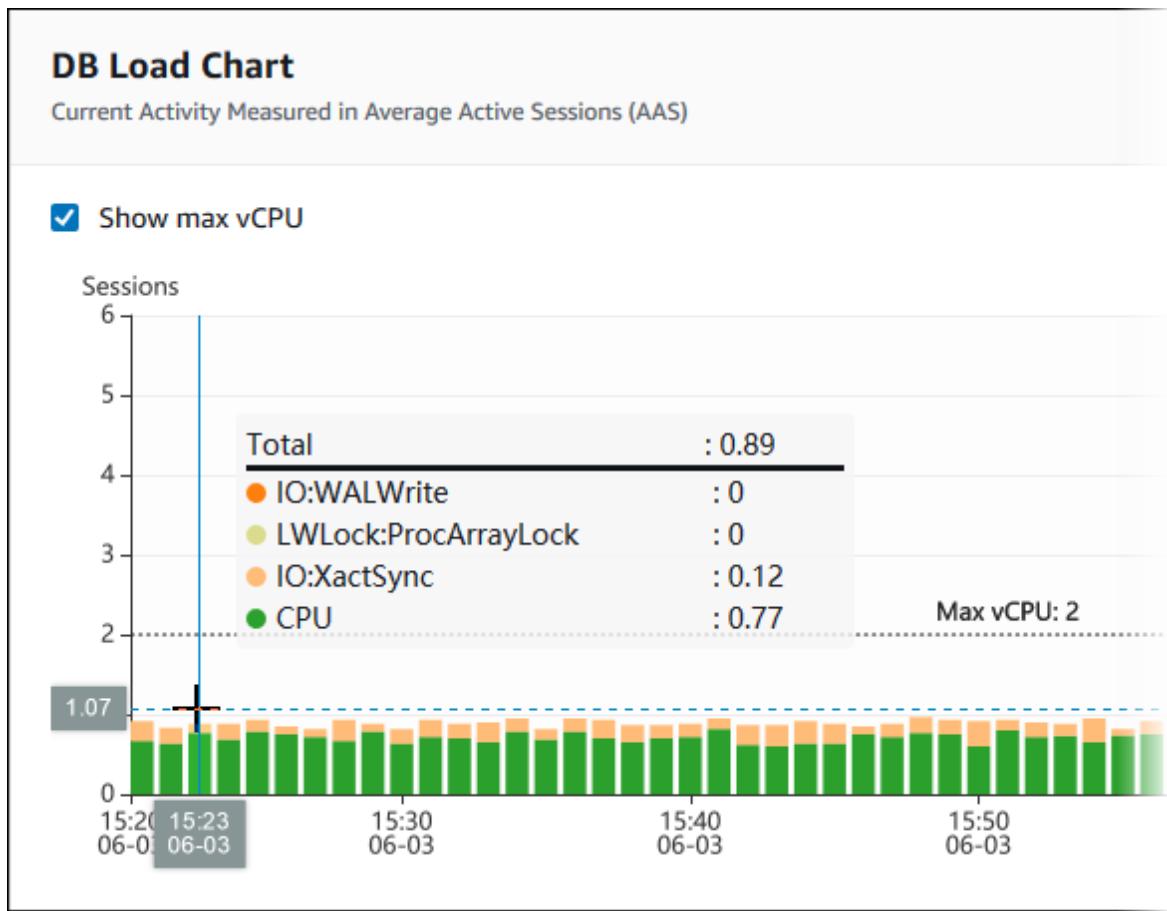

DB load details for a dimension item

To see details about a DB load item within a dimension, hover over the item name. The following image shows details for a SQL statement.

To see details for any item for the selected time period in the legend, hover over that item.

Top dimensions table

The Top dimensions table slices DB load by different dimensions. A dimension is a category or "slice by" for different characteristics of DB load. If the dimension is SQL, **Top SQL** shows the SQL statements that contribute the most to DB load.

Top waits	Top SQL	Top hosts	Top users	Top connections	Top databases	Top applications	Top session types
Top SQL (0) Learn more							
<input type="text"/> Find SQL statements							
Load by waits (AAS)				SQL statements			

Choose any of the following dimension tabs.

Tab	Description	Supported engines
Top SQL	The SQL statements that are currently running	All
Top waits	The event for which the database backend is waiting	All

Tab	Description	Supported engines
Top hosts	The host name of the connected client	All
Top users	The user logged in to the database	All
The name of the database to which the client is connected		
Top applications	The name of the application that is connected to the database	Aurora PostgreSQL only
Top session types	The type of the current session	Aurora PostgreSQL only

To learn how to analyze queries by using the **Top SQL** tab, see [Overview of the Top SQL tab \(p. 593\)](#).

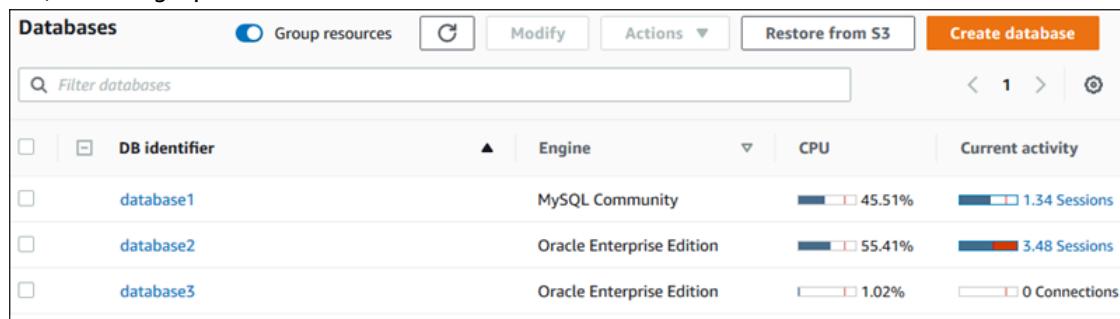

Opening the Performance Insights dashboard

To see the Performance Insights dashboard, use the following procedure.

To view the Performance Insights dashboard in the AWS Management Console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.

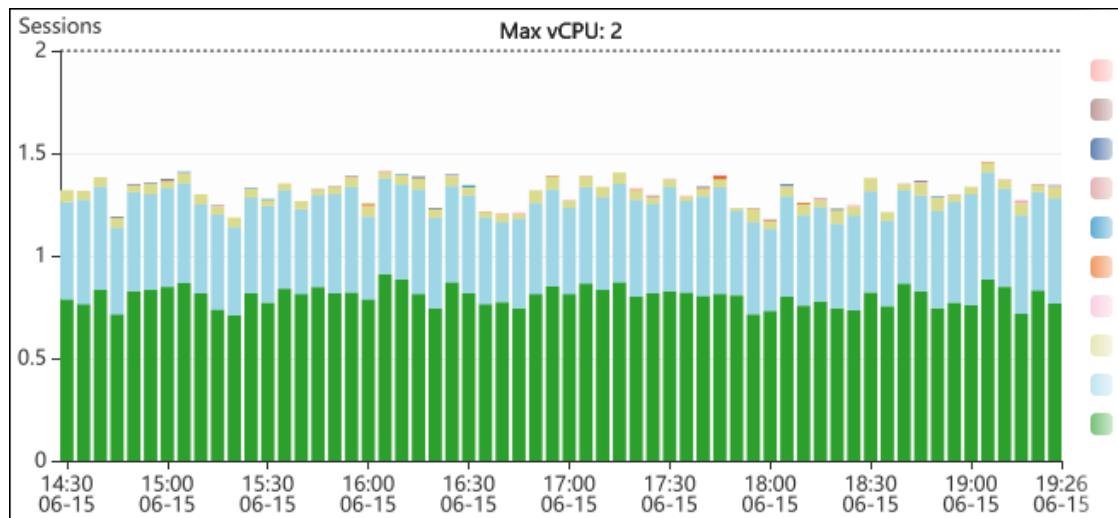

For DB instances with Performance Insights enabled, you can also reach the dashboard by choosing the **Sessions** item in the list of DB instances. Under **Current activity**, the **Sessions** item shows the database load in average active sessions over the last five minutes. The bar graphically shows the load. When the bar is empty, the DB instance is idle. As the load increases, the bar fills with blue. When the load passes the number of virtual CPUs (vCPUs) on the DB instance class, the bar turns red, indicating a potential bottleneck.

4. (Optional) Choose a different time interval by selecting a button in the upper right. For example, to change the interval to 5 hours, select **5h**.

In the following screenshot, the DB load interval is 5 hours.

5. (Optional) To refresh your data automatically, enable **Auto refresh**.

The Performance Insight dashboard automatically refreshes with new data. The refresh rate depends on the amount of data displayed:

- 5 minutes refreshes every 5 seconds.
- 1 hour refreshes every minute.
- 5 hours refreshes every minute.
- 24 hours refreshes every 5 minutes.
- 1 week refreshes every hour.

Analyzing DB load by wait events

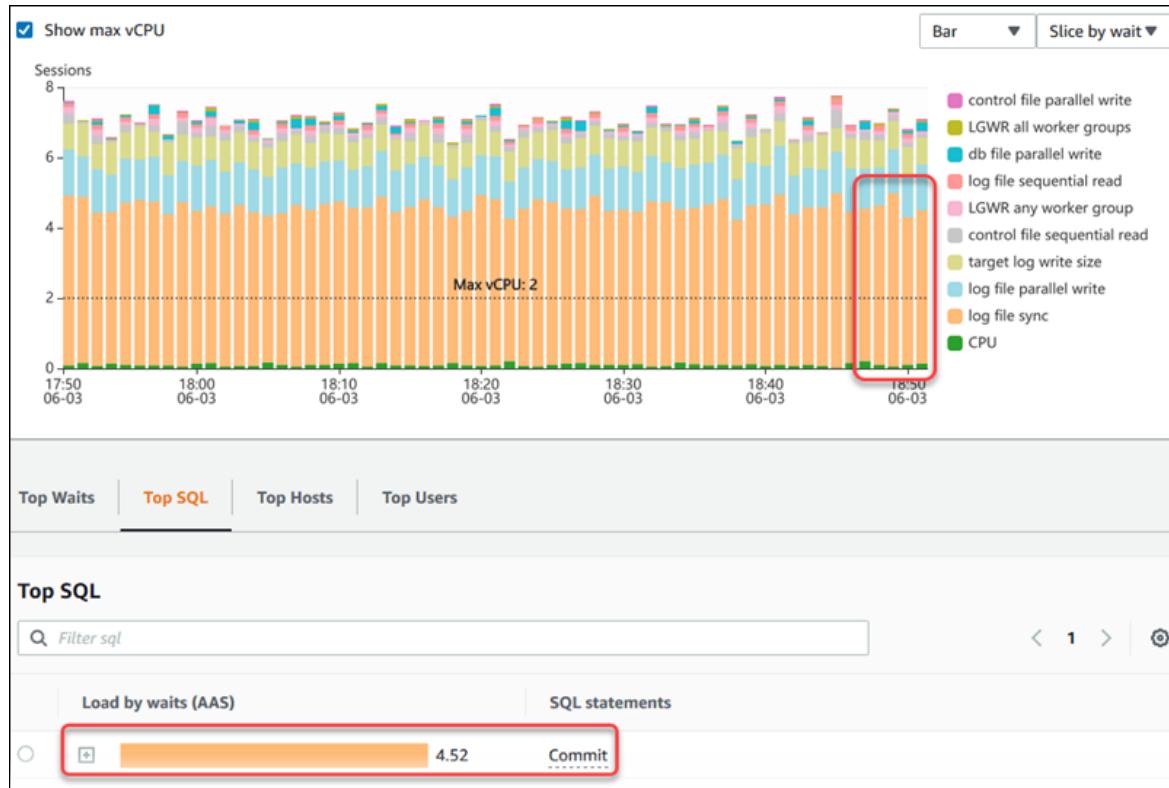

If the **Database load** chart shows a bottleneck, you can find out where the load is coming from. To do so, look at the top load items table below the **Database load** chart. Choose a particular item, like a SQL query or a user, to drill down into that item and see details about it.

DB load grouped by waits and top SQL queries is the default Performance Insights dashboard view. This combination typically provides the most insight into performance issues. DB load grouped by waits shows if there are any resource or concurrency bottlenecks in the database. In this case, the **SQL** tab of the top load items table shows which queries are driving that load.

Your typical workflow for diagnosing performance issues is as follows:

1. Review the **Database load** chart and see if there are any incidents of database load exceeding the **Max CPU** line.
2. If there is, look at the **Database load** chart and identify which wait state or states are primarily responsible.
3. Identify the digest queries causing the load by seeing which of the queries the **SQL** tab on the top load items table are contributing most to those wait states. You can identify these by the **DB Load by Wait** column.
4. Choose one of these digest queries in the **SQL** tab to expand it and see the child queries that it is composed of.

For example, in the dashboard following, **log file sync** waits account for most of the DB load. The **LGWR all worker groups** wait is also high. The **Top SQL** chart shows what is causing the **log file sync** waits: frequent COMMIT statements. In this case, committing less frequently will reduce DB load.

Analyzing running queries using the Performance Insights dashboard

In the Amazon RDS Performance Insights dashboard, you can find information about running queries in the **Top SQL** tab in the **Top dimensions** table. You can use this information to tune your queries.

Note

RDS for SQL Server doesn't show SQL-level statistics.

Topics

- [Overview of the Top SQL tab \(p. 593\)](#)
- [Analyzing running queries in Aurora MySQL \(p. 598\)](#)
- [Analyzing running queries in Aurora PostgreSQL \(p. 601\)](#)

Overview of the Top SQL tab

By default, the **Top SQL** tab shows the SQL queries that are contributing the most to DB load. To help tune your queries, you can analyze information such as the query text, statistics, and Support SQL ID. You can also choose the statistics that you want to appear in the **Top SQL** tab.

Topics

- [SQL statistics \(p. 594\)](#)
- [Load by waits \(AAS\) \(p. 594\)](#)
- [SQL information \(p. 595\)](#)

- [Preferences \(p. 596\)](#)

SQL statistics

SQL statistics are performance-related metrics about SQL queries. For example, Performance Insights might show executions per second or rows processed per second. Performance Insights collects statistics for only the most common queries. Typically, these match the top queries by load shown in the Performance Insights dashboard.

A *SQL digest* is a composite of multiple actual queries that are structurally similar but might have different literal values. The digest replaces hardcoded values with a question mark. For example, a digest might be `SELECT * FROM emp WHERE lname= ?`. This digest might include the following child queries:

```
SELECT * FROM emp WHERE lname = 'Miller'
SELECT * FROM emp WHERE lname = 'Olagappan'
SELECT * FROM emp WHERE lname = 'Wu'
```

Every line in the **Top SQL** table shows relevant statistics for the SQL statement or digest, as shown in the following example.

Top SQL		SQL statements	calls/sec	rows/sec
		select minute_rollups(?)	0.06	0.06
		select count(*) from authors where id < (select max(id) - 31 from authors) and...	33.68	101.04
		WITH cte AS (SELECT id FROM authors LIMIT ?) UPDATE ...	33.68	33.68
		delete from authors where id < (select * from (select max(id) - ? from authors...)	33.68	303.13
		INSERT INTO authors (id,name,email) VALUES (nextval(?),?,(nextval(?),?))	33.68	303.13
		select count(*) from authors where id < (select max(id) - 31 from authors) and...	0.00	0.00

To see the literal SQL statements in a digest, select the query, and then choose the plus symbol (+). In the following screenshot, the selected query is a digest.

Load by waits (AAS)	SQL statements
0.88	select minute_rollups(?)
0.50	select minute_rollups(1000000)
0.53	select count(*) from authors where id < (select max(id) - 31 from authors) and...

Note

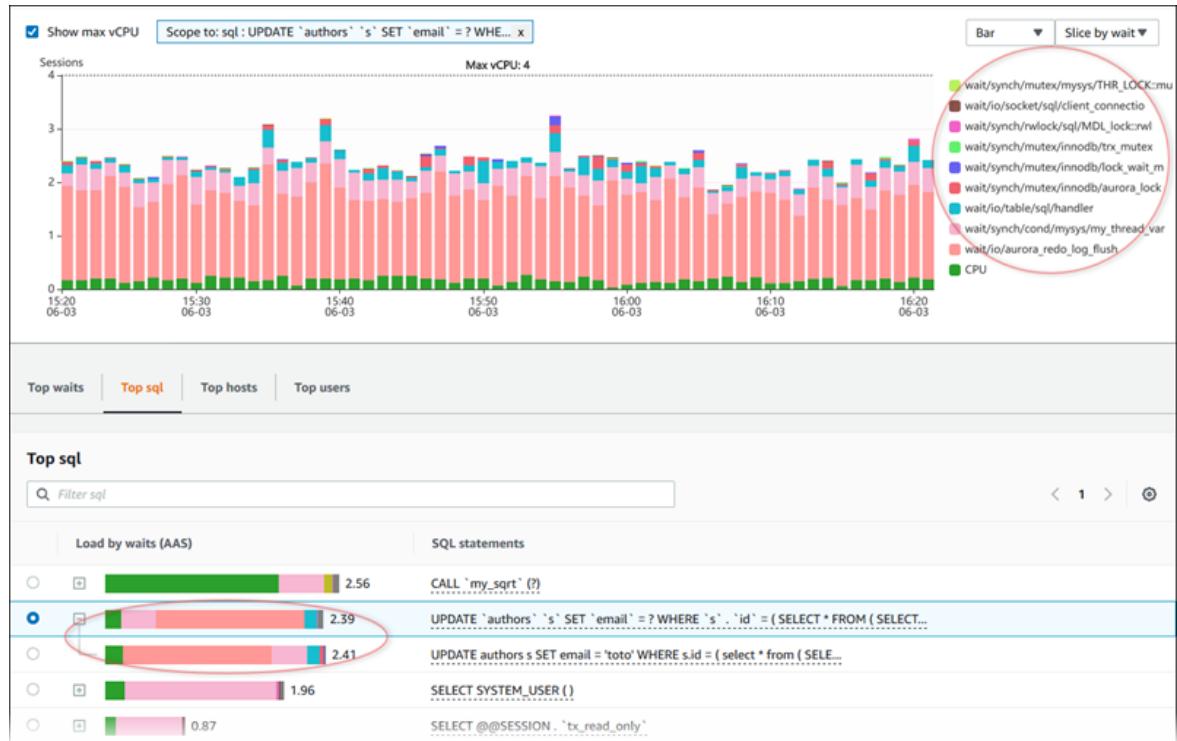

A SQL digest groups similar SQL statements, but does not redact sensitive information.

Load by waits (AAS)

In **Top SQL**, the **Load by waits (AAS)** column illustrates the percentage of the database load associated with each top load item. This column reflects the load for that item by whatever grouping is currently selected in the **DB Load Chart**.

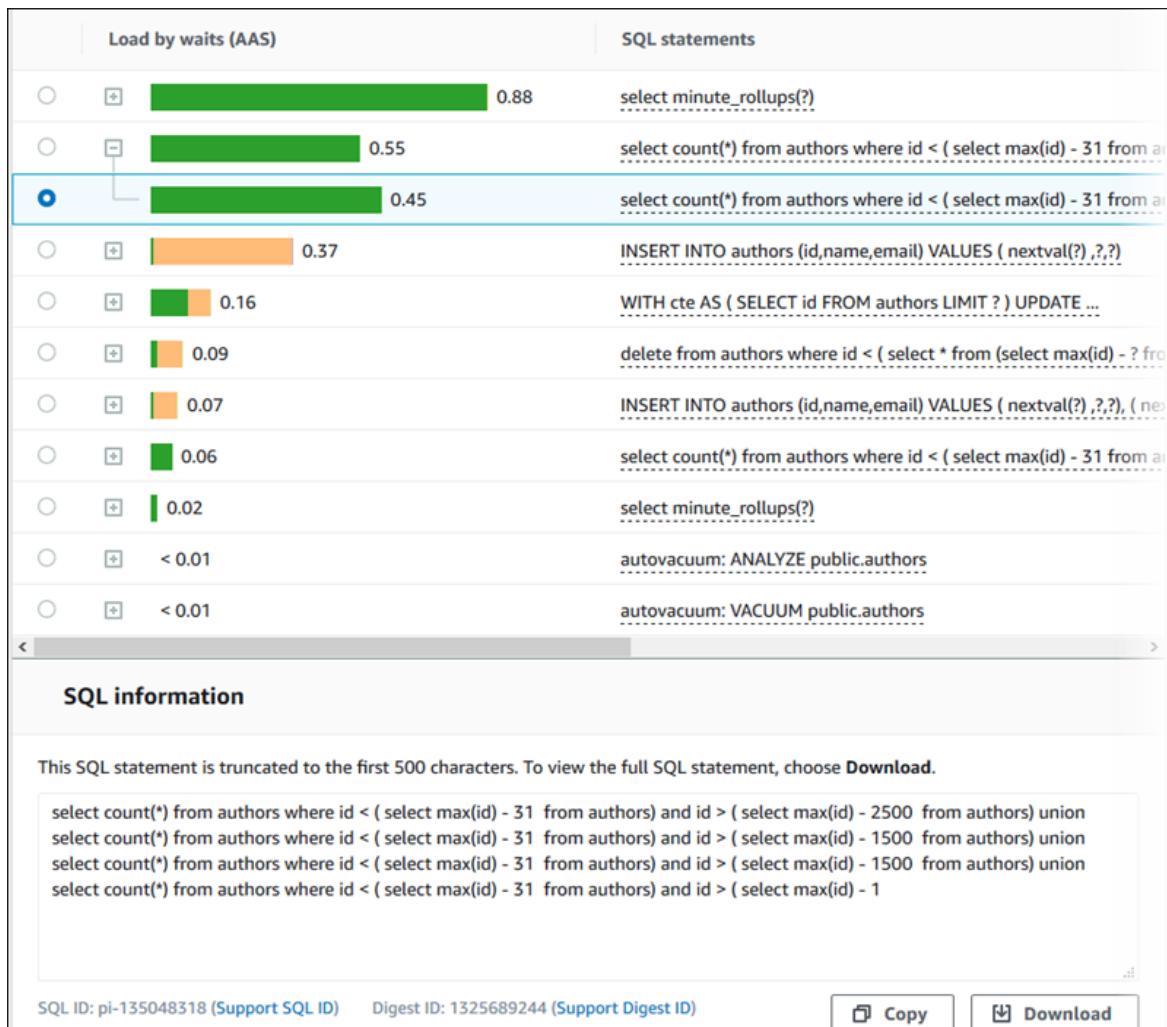

For example, you might group the **DB load** chart by wait states. You examine SQL queries in the top load items table. In this case, the **DB Load by Waits** bar is sized, segmented, and color-coded to show how

much of a given wait state that query is contributing to. It also shows which wait states are affecting the selected query.

SQL information

In the **Top SQL** table, you can open a statement to view its information. The information appears in the bottom pane.

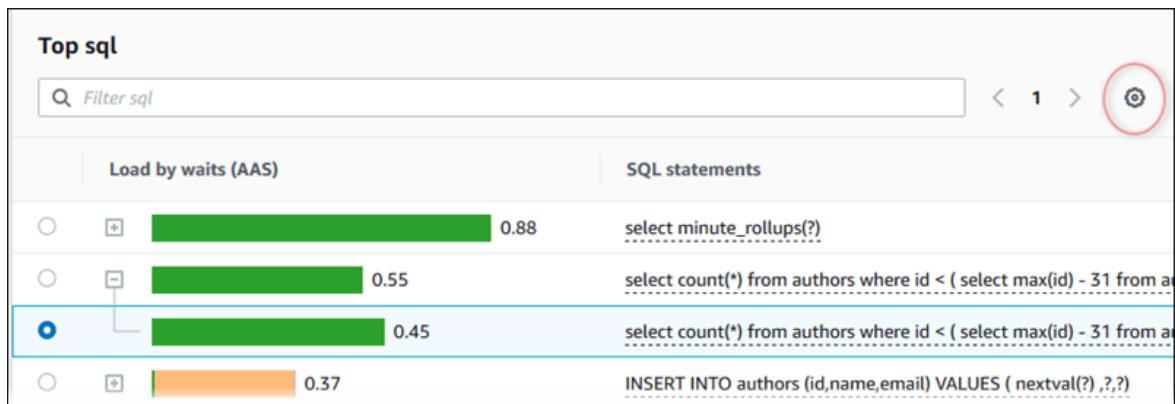

The following types of identifiers (IDs) that are associated with SQL statements:

- **Support SQL ID** – A hash value of the SQL ID. This value is only for referencing a SQL ID when you are working with AWS Support. AWS Support doesn't have access to your actual SQL IDs and SQL text.
- **Support Digest ID** – A hash value of the digest ID. This value is only for referencing a digest ID when you are working with AWS Support. AWS Support doesn't have access to your actual digest IDs and SQL text.

Preferences

You can control the statistics displayed in the **Top SQL** tab by choosing the **Preferences** icon.

When you choose the **Preferences** icon, the **Preferences** window opens.

The Preferences window allows you to select which metrics are displayed in the Top SQL tab. Most checkboxes are currently selected (indicated by a blue circle).

Metric	Status
Load by waits (AAS)	Selected
SQL statements	Selected
calls/sec (calls_per_sec)	Selected
rows/sec (rows_per_sec)	Selected
AAE (total_time_per_sec)	Selected
blk hits/sec (shared_blk_hits_per_sec)	Selected
blk reads/sec (shared_blk_reads_per_sec)	Selected
blk dirty/sec (shared_blk_dirty_per_sec)	Selected
blk writes/sec (shared_blk_written_per_sec)	Selected
local blk hits/sec (local_blk_hits_per_sec)	Selected
local blk reads/sec (local_blk_reads_per_sec)	Selected
local blk dirty/sec (local_blk_dirty_per_sec)	Selected

To enable the statistics that you want to appear in the **Top SQL** tab, use your mouse to scroll to the bottom of the window, and then choose **Continue**.

Analyzing running queries in Aurora MySQL

Aurora MySQL collect SQL statistics only at the digest level. No statistics are shown at the statement level.

Topics

- [Digest table in Aurora MySQL \(p. 598\)](#)
- [Per-second statistics for Aurora MySQL \(p. 598\)](#)
- [Per-call statistics for Aurora MySQL \(p. 599\)](#)
- [Viewing SQL statistics for Aurora MySQL \(p. 599\)](#)

Digest table in Aurora MySQL

Performance Insights collects SQL digest statistics from the `events_statements_summary_by_digest` table. The `events_statements_summary_by_digest` table is managed by your database.

The digest table doesn't have an eviction policy. When the table is full, the AWS Management Console shows the following message:

Performance Insights is unable to collect SQL Digest statistics on new queries because the table `events_statements_summary_by_digest` is full.
Please truncate `events_statements_summary_by_digest` table to clear the issue. Check the User Guide for more details.

In this situation, Aurora MySQL doesn't track SQL queries. To address this issue, Performance Insights automatically truncates the digest table when both of the following conditions are met:

- The table is full.
- Performance Insights manages the Performance Schema automatically. For automatic management, the `performance_schema` parameter must be set to 0 and the **Source** must not be set to `user`.

If Performance Insights isn't managing the Performance Schema automatically, see [Enabling the Performance Schema for Performance Insights on Aurora MySQL \(p. 580\)](#).

In the AWS CLI, check the source of a parameter value by running the `describe-db-parameters` command.

Per-second statistics for Aurora MySQL

The following SQL statistics are available for Aurora MySQL DB clusters.

Metric	Unit
<code>db.sql_tokenized.stats.count_star_per_sec</code>	Calls per second
<code>db.sql_tokenized.stats.sum_timer_wait_per_sec</code>	Average active executions per second (AAE)
<code>db.sql_tokenized.stats.sum_select_full_join_per_sec</code>	Select full join per second
<code>db.sql_tokenized.stats.sum_select_range_check_per_sec</code>	Select range check per second
<code>db.sql_tokenized.stats.sum_select_scan_per_sec</code>	Select scan per second
<code>db.sql_tokenized.stats.sum_sort_merge_passes_per_sec</code>	Sort merge passes per second
<code>db.sql_tokenized.stats.sum_sort_scan_per_sec</code>	Sort scans per second

Metric	Unit
db.sql_tokenized.stats.sum_sort_range_per_sec	Sort ranges per second
db.sql_tokenized.stats.sum_sort_rows_per_sec	Sort rows per second
db.sql_tokenized.stats.sum_rows_affected_per_sec	Rows affected per second
db.sql_tokenized.stats.sum_rows_examined_per_sec	Rows examined per second
db.sql_tokenized.stats.sum_rows_sent_per_sec	Rows sent per second
db.sql_tokenized.stats.sum_created_tmp_disk_tables	Created temporary disk tables per second
db.sql_tokenized.stats.sum_created_tmp_tables_per_sec	Created temporary tables per second
db.sql_tokenized.stats.sum_lock_time_per_sec	Lock time per second (in ms)

Per-call statistics for Aurora MySQL

The following metrics provide per call statistics for a SQL statement.

Metric	Unit
db.sql_tokenized.stats.sum_timer_wait_per_call	Average latency per call (in ms)
db.sql_tokenized.stats.sum_select_full_join_per_call	Select full joins per call
db.sql_tokenized.stats.sum_select_range_check_per_call	Select range check per call
db.sql_tokenized.stats.sum_select_scan_per_call	Select scans per call
db.sql_tokenized.stats.sum_sort_merge_passes_per_call	Sort merge passes per call
db.sql_tokenized.stats.sum_sort_scan_per_call	Sort scans per call
db.sql_tokenized.stats.sum_sort_range_per_call	Sort ranges per call
db.sql_tokenized.stats.sum_sort_rows_per_call	Sort rows per call
db.sql_tokenized.stats.sum_rows_affected_per_call	Rows affected per call
db.sql_tokenized.stats.sum_rows_examined_per_call	Rows examined per call
db.sql_tokenized.stats.sum_rows_sent_per_call	Rows sent per call
db.sql_tokenized.stats.sum_created_tmp_disk_tables	Created temporary disk tables per call
db.sql_tokenized.stats.sum_created_tmp_tables_per_call	Created temporary tables per call
db.sql_tokenized.stats.sum_lock_time_per_call	Lock time per call (in ms)

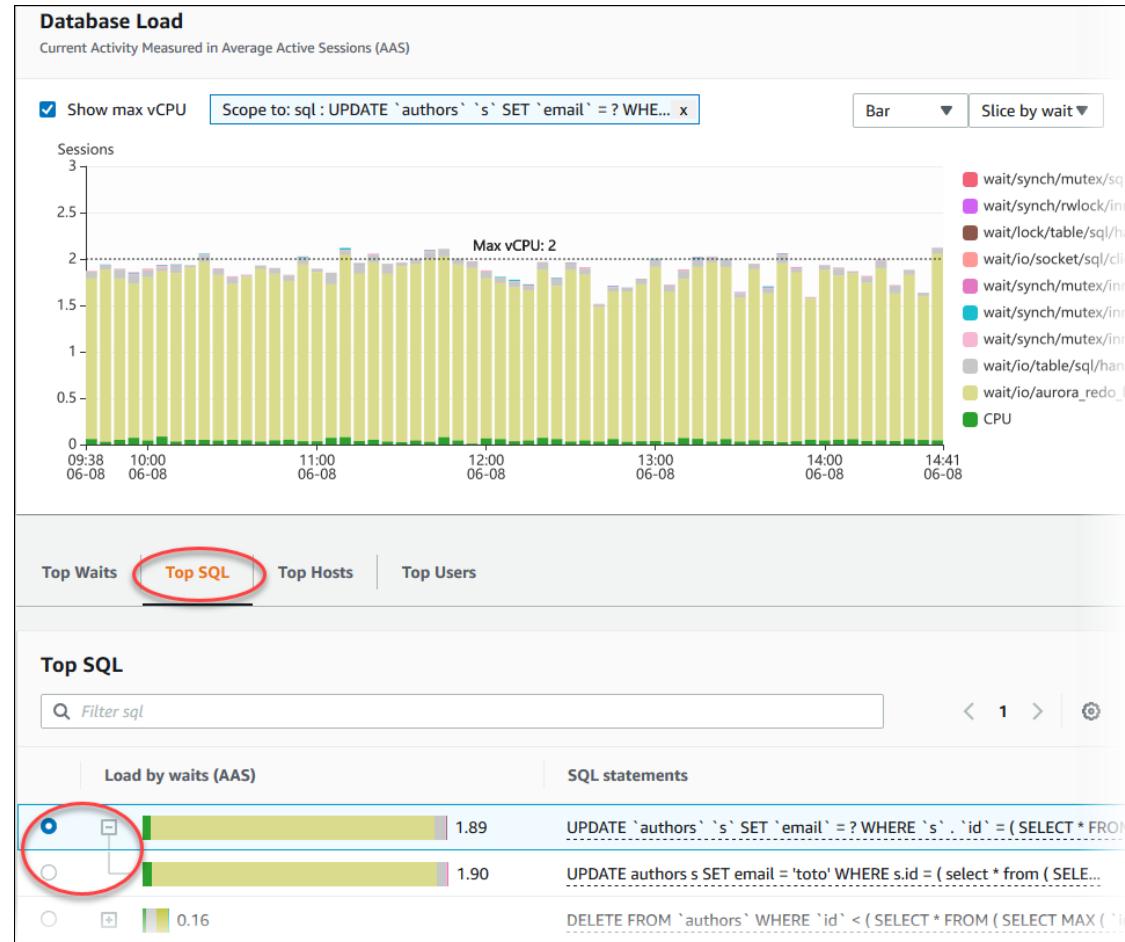

Viewing SQL statistics for Aurora MySQL

The statistics are available in the **Top SQL** tab of the **Database load** chart.

To view the SQL statistics

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

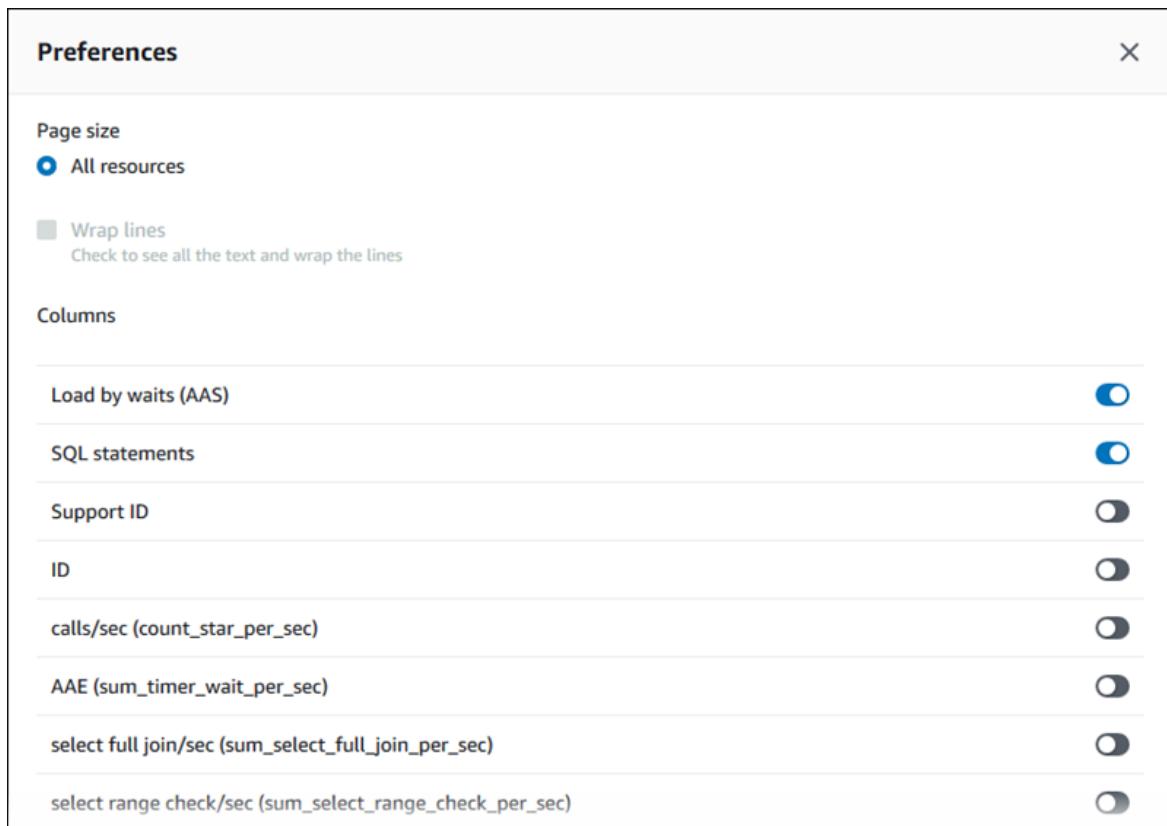

2. Go to the Performance Insights dashboard.
3. Choose the **SQL** tab and expand a query.

4.

Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart.

The following screenshot shows the preferences for Aurora MySQL DB instances.

Analyzing running queries in Aurora PostgreSQL

Aurora PostgreSQL collects SQL statistics only at the digest level. No statistics are shown at the statement level.

Topics

- [Digest statistics for Aurora PostgreSQL \(p. 601\)](#)
- [Per-second digest statistics for Aurora PostgreSQL \(p. 602\)](#)
- [Per-call digest statistics for Aurora PostgreSQL \(p. 602\)](#)
- [Viewing SQL statistics for Aurora PostgreSQL \(p. 603\)](#)

Digest statistics for Aurora PostgreSQL

To view SQL digest statistics, the `pg_stat_statements` library must be loaded. For Aurora PostgreSQL DB clusters that are compatible with PostgreSQL 10, this library is loaded by default. For Aurora PostgreSQL DB clusters that are compatible with PostgreSQL 9.6, you enable this library manually. To enable it manually, add `pg_stat_statements` to `shared_preload_libraries` in the DB parameter group associated with the DB instance. Then reboot your DB instance. For more information, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#).

Note

Performance Insights can only collect statistics for queries in `pg_stat_activity` that aren't truncated. By default, PostgreSQL databases truncate queries longer than 1,024 bytes. To increase the query size, change the `track_activity_query_size` parameter in the DB parameter group associated with your DB instance. When you change this parameter, a DB instance reboot is required.

Per-second digest statistics for Aurora PostgreSQL

The following SQL digest statistics are available for Aurora PostgreSQL DB instances.

Metric	Unit
db.sql_tokenized.stats.calls_per_sec	Calls per second
db.sql_tokenized.stats.rows_per_sec	Rows per second
db.sql_tokenized.stats.total_time_per_sec	Average active executions per second (AAE)
db.sql_tokenized.stats.shared_blk_hit_per_sec	Block hits per second
db.sql_tokenized.stats.shared_blk_read_per_sec	Block reads per second
db.sql_tokenized.stats.shared_blk_dirtied_per_sec	Blocks dirtied per second
db.sql_tokenized.stats.shared_blk_written_per_sec	Block writes per second
db.sql_tokenized.stats.local_blk_hit_per_sec	Local block hits per second
db.sql_tokenized.stats.local_blk_read_per_sec	Local block reads per second
db.sql_tokenized.stats.local_blk_dirtied_per_sec	Local block dirty per second
db.sql_tokenized.stats.local_blk_written_per_sec	Local block writes per second
db.sql_tokenized.stats.temp_blk_written_per_sec	Temporary writes per second
db.sql_tokenized.stats.temp_blk_read_per_sec	Temporary reads per second
db.sql_tokenized.stats.blk_read_time_per_sec	Average concurrent reads per second
db.sql_tokenized.stats.blk_write_time_per_sec	Average concurrent writes per second

Per-call digest statistics for Aurora PostgreSQL

The following metrics provide per call statistics for a SQL statement.

Metric	Unit
db.sql_tokenized.stats.rows_per_call	Rows per call
db.sql_tokenized.stats.avg_latency_per_call	Average latency per call (in ms)
db.sql_tokenized.stats.shared_blk_hit_per_call	Block hits per call
db.sql_tokenized.stats.shared_blk_read_per_call	Block reads per call
db.sql_tokenized.stats.shared_blk_written_per_call	Block writes per call
db.sql_tokenized.stats.shared_blk_dirtied_per_call	Blocks dirtied per call
db.sql_tokenized.stats.local_blk_hit_per_call	Local block hits per call
db.sql_tokenized.stats.local_blk_read_per_call	Local block reads per call
db.sql_tokenized.stats.local_blk_dirtied_per_call	Local block dirty per call
db.sql_tokenized.stats.local_blk_written_per_call	Local block writes per call

Metric	Unit
db.sql_tokenized.stats.temp_blk_written_per_call	Temporary block writes per call
db.sql_tokenized.stats.temp_blk_read_per_call	Temporary block reads per call
db.sql_tokenized.stats.blk_read_time_per_call	Read time per call (in ms)
db.sql_tokenized.stats.blk_write_time_per_call	Write time per call (in ms)

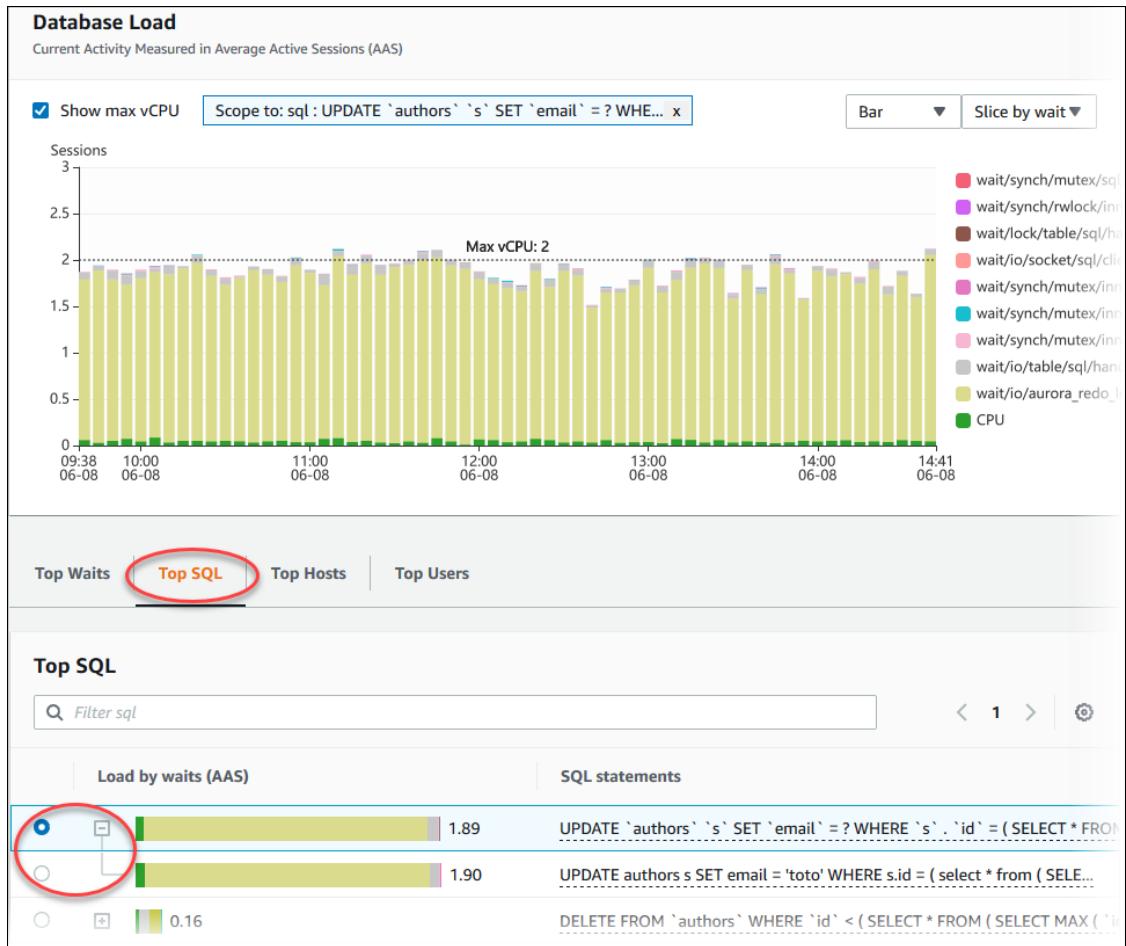

For more information about these metrics, see [pg_stat_statements](#) in the PostgreSQL documentation.

Viewing SQL statistics for Aurora PostgreSQL

The statistics are available in the **Top SQL** tab of the **Database load** chart.

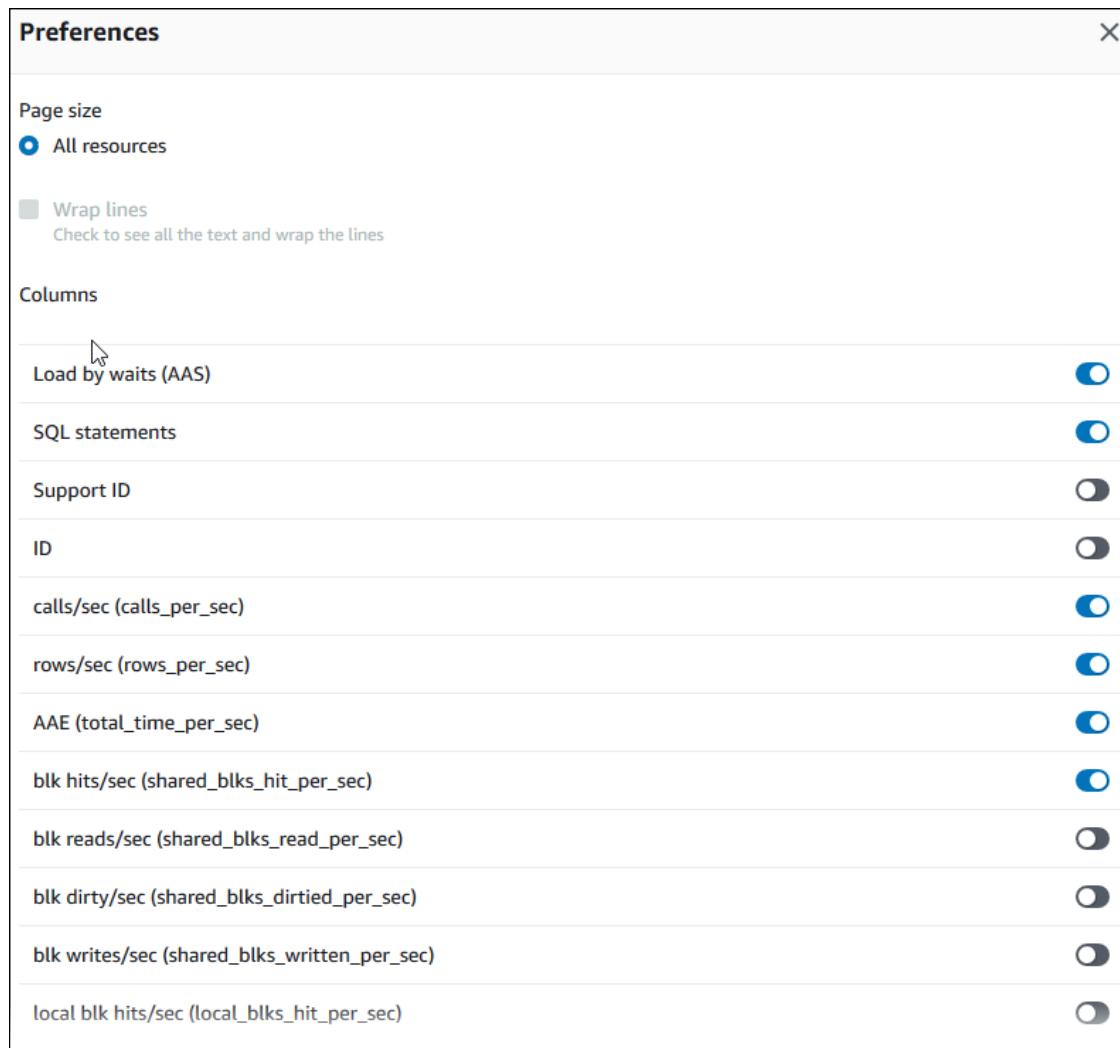

To view the SQL statistics

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Go to the Performance Insights dashboard.
3. Choose the **SQL** tab.

4. Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart.

The following screenshot shows the preferences for Aurora PostgreSQL.

Accessing the text of SQL statements

By default, each row in the **Top SQL** table shows 500 bytes of SQL text for each SQL statement. When a SQL statement exceeds 500 bytes, you can view more text by opening the statement in the Performance Insights dashboard. In this case, the maximum length for the displayed query is 4 KB. This limit is introduced by the console and is subject to the limits set by the database engine. If you view a child SQL statement, you can also choose **Download**.

Topics

- [Text size limits for Aurora MySQL \(p. 604\)](#)
- [Setting the SQL text limit for Aurora PostgreSQL DB instances \(p. 605\)](#)
- [Viewing and downloading SQL text in the Performance Insights dashboard \(p. 605\)](#)

Text size limits for Aurora MySQL

When you download a SQL statement, the database engine determines the maximum length of the text. You can download text up to the following per-engine limits:

- Aurora MySQL 5.7 – 4,096 bytes
- Aurora MySQL 5.6 – 1,024 bytes

The Performance Insights console displays up to the maximum that the engine returns. For example, if Aurora MySQL returns at most 1 KB to Performance Insights, it can only collect and show 1 KB, even if the original query is larger. Thus, when you view or download the query, Performance Insights returns the same number of bytes.

If you use the AWS CLI or API, Performance Insights doesn't have the 4 KB limit enforced by the console. `DescribeDimensionKeys` and `GetResourceMetrics` return at most 500 bytes. `GetDimensionKeyDetails` returns the full query, but the size is subject to the engine limit.

Setting the SQL text limit for Aurora PostgreSQL DB instances

Aurora PostgreSQL handles text differently. You can set the text size limit with the DB instance parameter `track_activity_query_size`. This parameter has the following characteristics:

Default text size

On Aurora PostgreSQL version 9.6, the default setting for the `track_activity_query_size` parameter is 1,024 bytes. On Aurora PostgreSQL version 10 or higher, the default is 4,096 bytes.

Maximum text size

The limit for `track_activity_query_size` is 102,400 bytes for Aurora PostgreSQL version 12 and lower. The maximum is 1 MB for version 13 and higher.

If the engine returns 1 MB to Performance Insights, the console displays only the first 4 KB. If you download the query, you get the full 1 MB. In this case, viewing and downloading return different numbers of bytes. For more information about the `track_activity_query_size` DB instance parameter, see [Run-time Statistics](#) in the PostgreSQL documentation.

To increase the SQL text size, increase the `track_activity_query_size` limit. To modify the parameter, change the parameter setting in the parameter group that is associated with the Aurora PostgreSQL DB instance.

To change the setting when the instance uses the default parameter group

1. Create a new DB instance parameter group for the appropriate DB engine and DB engine version.
2. Set the parameter in the new parameter group.
3. Associate the new parameter group with the DB instance.

For information about setting a DB instance parameter, see [Modifying parameters in a DB parameter group \(p. 347\)](#).

Viewing and downloading SQL text in the Performance Insights dashboard

In the Performance Insights dashboard, you can view or download SQL text.

To view more SQL text in the Performance Insights dashboard

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is displayed for that DB instance.

SQL statements with text larger than 500 bytes look similar to the following image.

The screenshot shows the 'Top SQL' section of the Performance Insights dashboard. It includes a search bar labeled 'Filter sql', a legend for 'Load by waits (AAS)', and three rows of SQL statements with their execution times:

SQL Statement	Execution Time
delete from authors where id < (select * from (select max(id) - ? from authors)	1.07
select count(*) from authors where id < (select max(id) - ? from authors)	0.99
select count(*) from authors where id < (select max(id) - 30 from autho	0.99

Below this, a 'SQL information' panel displays the full SQL text for the third statement, along with 'SQL ID' and 'Digest ID' links.

- Examine the SQL information section to view more of the SQL text.

The Performance Insights dashboard can display up to 4,096 bytes for each SQL statement.

- (Optional) Choose **Copy** to copy the displayed SQL statement, or choose **Download** to download the SQL statement to view the SQL text up to the DB engine limit.

Note

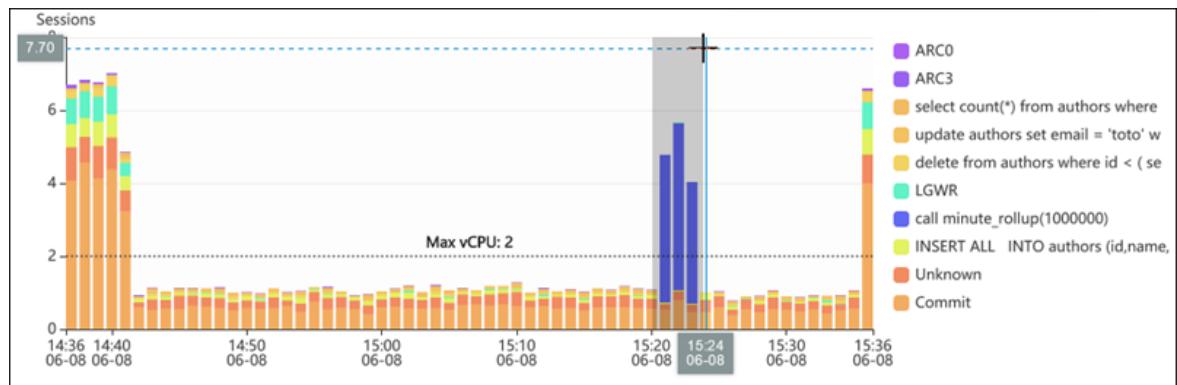

To copy or download the SQL statement, disable pop-up blockers.

Zooming In on the DB Load chart

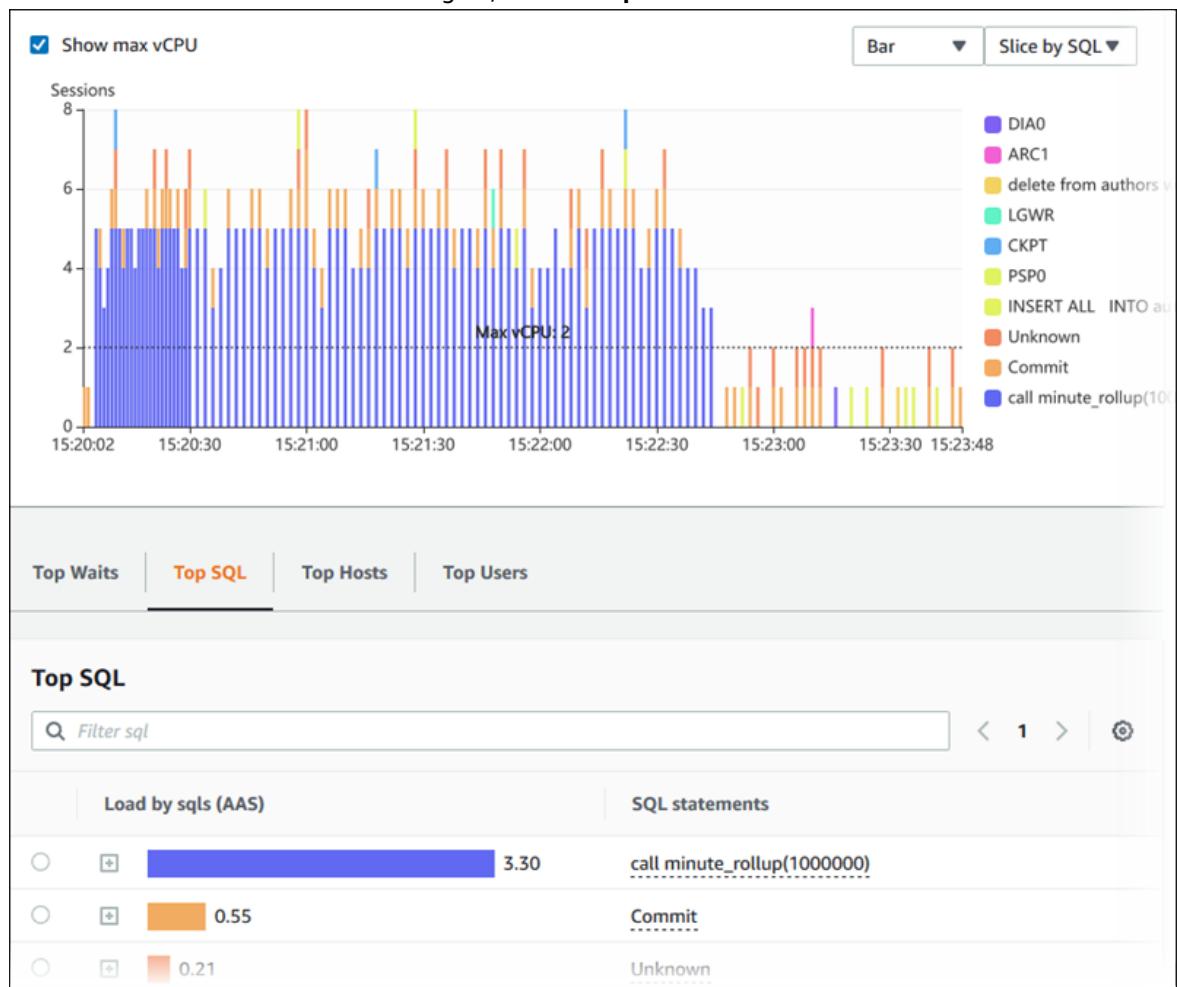

You can use other features of the Performance Insights user interface to help analyze performance data.

Click-and-Drag Zoom In

In the Performance Insights interface, you can choose a small portion of the load chart and zoom in on the detail.

To zoom in on a portion of the load chart, choose the start time and drag to the end of the time period you want. When you do this, the selected area is highlighted. When you release the mouse, the load chart zooms in on the selected AWS Region, and the **Top items** table is recalculated.

Retrieving metrics with the Performance Insights API

When Performance Insights is enabled, the API provides visibility into instance performance. Amazon CloudWatch Logs provides the authoritative source for vended monitoring metrics for AWS services.

Performance Insights offers a domain-specific view of database load measured as average active sessions (AAS). This metric appears to API consumers as a two-dimensional time-series dataset. The time dimension of the data provides DB load data for each time point in the queried time range. Each time point decomposes overall load in relation to the requested dimensions, such as `SQL`, `Wait-event`, `User`, or `Host`, measured at that time point.

Amazon RDS Performance Insights monitors your Amazon Aurora cluster so that you can analyze and troubleshoot database performance. One way to view Performance Insights data is in the AWS Management Console. Performance Insights also provides a public API so that you can query your own data. You can use the API to do the following:

- Offload data into a database
- Add Performance Insights data to existing monitoring dashboards
- Build monitoring tools

To use the Performance Insights API, enable Performance Insights on one of your Amazon RDS DB instances. For information about enabling Performance Insights, see [Enabling and disabling Performance Insights \(p. 577\)](#). For more information about the Performance Insights API, see the [Amazon RDS Performance Insights API Reference](#).

The Performance Insights API provides the following operations.

Performance Insights action	AWS CLI command	Description
DescribeDimensionKeys	<code>aws pi describe-dimension-keys</code>	Retrieves the top N dimension keys for a metric for a specific time period.
GetDimensionKeyDetails	<code>aws pi get-dimension-key-details</code>	Retrieves the attributes of the specified dimension group for a DB instance or data source. For example, if you specify a SQL ID, and if the dimension details are available, <code>GetDimensionKeyDetails</code> retrieves the full text of the dimension <code>db.sql.statement</code> associated with this ID. This operation is useful because <code>GetResourceMetrics</code> and <code>DescribeDimensionKeys</code> don't support retrieval of large SQL statement text.
GetResourceMetadata	<code>aws pi get-resource-metadata</code>	Retrieve the metadata for different features. For example, the metadata might indicate that a feature is turned on or off on a specific DB instance.
GetResourceMetrics	<code>aws pi get-resource-metrics</code>	Retrieves Performance Insights metrics for a set of data sources over a time period. You can provide specific dimension groups and dimensions, and provide aggregation and filtering criteria for each group.

Performance Insights action	AWS CLI command	Description
ListAvailableResourceDimensions	aws pi list-available-resource-dimensions	Retrieve the dimensions that can be queried for each specified metric type on a specified instance.
ListAvailableResourceMetrics	aws pi list-available-resource-metrics	Retrieve all available metrics of the specified metric types that can be queried for a specified DB instance.

Topics

- [AWS CLI for Performance Insights \(p. 609\)](#)
- [Retrieving time-series metrics \(p. 609\)](#)
- [AWS CLI examples for Performance Insights \(p. 610\)](#)

AWS CLI for Performance Insights

You can view Performance Insights data using the AWS CLI. You can view help for the AWS CLI commands for Performance Insights by entering the following on the command line.

```
aws pi help
```

If you don't have the AWS CLI installed, see [Installing the AWS Command Line Interface](#) in the *AWS CLI User Guide* for information about installing it.

Retrieving time-series metrics

The GetResourceMetrics operation retrieves one or more time-series metrics from the Performance Insights data. GetResourceMetrics requires a metric and time period, and returns a response with a list of data points.

For example, the AWS Management Console uses GetResourceMetrics to populate the **Counter Metrics** chart and the **Database Load** chart, as seen in the following image.

All metrics returned by `GetResourceMetrics` are standard time-series metrics, with the exception of `db.load`. This metric is displayed in the **Database Load** chart. The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called *dimensions*. In the previous image, `db.load` is broken down and grouped by the waits states that make up the `db.load`.

Note

`GetResourceMetrics` can also return the `db.sampleload` metric, but the `db.load` metric is appropriate in most cases.

For information about the counter metrics returned by `GetResourceMetrics`, see [Performance Insights counter metrics \(p. 653\)](#).

The following calculations are supported for the metrics:

- Average – The average value for the metric over a period of time. Append `.avg` to the metric name.
- Minimum – The minimum value for the metric over a period of time. Append `.min` to the metric name.
- Maximum – The maximum value for the metric over a period of time. Append `.max` to the metric name.
- Sum – The sum of the metric values over a period of time. Append `.sum` to the metric name.
- Sample count – The number of times the metric was collected over a period of time. Append `.sample_count` to the metric name.

For example, assume that a metric is collected for 300 seconds (5 minutes), and that the metric is collected one time each minute. The values for each minute are 1, 2, 3, 4, and 5. In this case, the following calculations are returned:

- Average – 3
- Minimum – 1
- Maximum – 5
- Sum – 15
- Sample count – 5

For information about using the `get-resource-metrics` AWS CLI command, see [get-resource-metrics](#).

For the `--metric-queries` option, specify one or more queries that you want to get results for. Each query consists of a mandatory `Metric` and optional `GroupBy` and `Filter` parameters. The following is an example of a `--metric-queries` option specification.

```
{  
    "Metric": "string",  
    "GroupBy": {  
        "Group": "string",  
        "Dimensions": ["string", ...],  
        "Limit": integer  
    },  
    "Filter": {"string": "string"  
    ...}
```

AWS CLI examples for Performance Insights

The following examples show how to use the AWS CLI for Performance Insights.

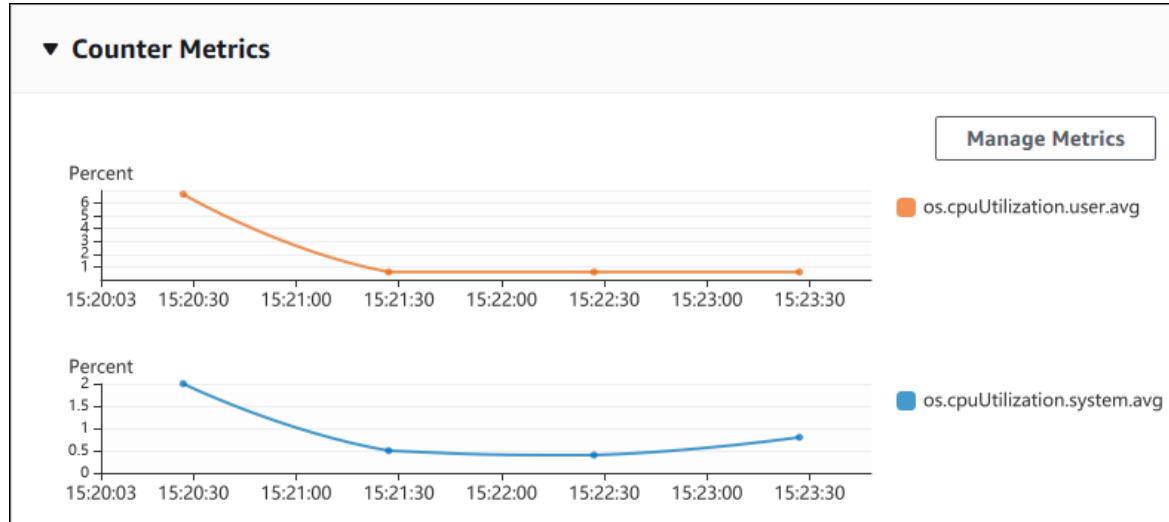

Topics

- [Retrieving counter metrics \(p. 611\)](#)

- [Retrieving the DB load average for top wait events \(p. 613\)](#)
- [Retrieving the DB load average for top SQL \(p. 615\)](#)
- [Retrieving the DB load average filtered by SQL \(p. 617\)](#)
- [Retrieving the full text of a SQL statement \(p. 620\)](#)

Retrieving counter metrics

The following screenshot shows two counter metrics charts in the AWS Management Console.

The following example shows how to gather the same data that the AWS Management Console uses to generate the two counter metric charts.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries '[{"Metric": "os.cpuUtilization.user.avg" },
 {"Metric": "os.cpuUtilization.idle.avg"}]'
```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries '[{"Metric": "os.cpuUtilization.user.avg" },
 {"Metric": "os.cpuUtilization.idle.avg"}]'
```

You can also make a command easier to read by specifying a file for the `--metrics-query` option. The following example uses a file called `query.json` for the option. The file has the following contents.

```
[
```

```
{  
    "Metric": "os.cpuUtilization.user.avg"  
},  
{  
    "Metric": "os.cpuUtilization.idle.avg"  
}  
]
```

Run the following command to use the file.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \  
    --service-type RDS \  
    --identifier db-ID \  
    --start-time 2018-10-30T00:00:00Z \  
    --end-time 2018-10-30T01:00:00Z \  
    --period-in-seconds 60 \  
    --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^  
    --service-type RDS ^  
    --identifier db-ID ^  
    --start-time 2018-10-30T00:00:00Z ^  
    --end-time 2018-10-30T01:00:00Z ^  
    --period-in-seconds 60 ^  
    --metric-queries file://query.json
```

The preceding example specifies the following values for the options:

- **--service-type** – RDS for Amazon RDS
- **--identifier** – The resource ID for the DB instance
- **--start-time** and **--end-time** – The ISO 8601 DateTime values for the period to query, with multiple supported formats

It queries for a one-hour time range:

- **--period-in-seconds** – 60 for a per-minute query
- **--metric-queries** – An array of two queries, each just for one metric.

The metric name uses dots to classify the metric in a useful category, with the final element being a function. In the example, the function is `avg` for each query. As with Amazon CloudWatch, the supported functions are `min`, `max`, `total`, and `avg`.

The response looks similar to the following.

```
{  
    "Identifier": "db-XXX",  
    "AlignedStartTime": 1540857600.0,  
    "AlignedEndTime": 1540861200.0,  
    "MetricList": [  
        { //A list of key/datapoints  
            "Key": {  
                "Metric": "os.cpuUtilization.user.avg" //Metric1  
            },  
            "DataPoints": [  
                {  
                    "Time": 1540857600.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857620.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857640.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857660.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857680.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857700.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857720.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857740.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857760.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857780.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857800.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857820.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857840.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857860.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857880.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857900.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857920.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857940.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857960.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540857980.0,  
                    "Value": 0.5  
                },  
                {  
                    "Time": 1540858000.0,  
                    "Value": 0.5  
                }  
            ]  
        }  
    ]  
}
```

```

//Each list of datapoints has the same timestamps and same number of items
{
    "Timestamp": 1540857660.0, //Minute1
    "Value": 4.0
},
{
    "Timestamp": 1540857720.0, //Minute2
    "Value": 4.0
},
{
    "Timestamp": 1540857780.0, //Minute 3
    "Value": 10.0
}
//... 60 datapoints for the os.cpuUtilization.user.avg metric
]
},
{
    "Key": {
        "Metric": "os.cpuUtilization.idle.avg" //Metric2
    },
    "DataPoints": [
        {
            "Timestamp": 1540857660.0, //Minute1
            "Value": 12.0
        },
        {
            "Timestamp": 1540857720.0, //Minute2
            "Value": 13.5
        }
        //... 60 datapoints for the os.cpuUtilization.idle.avg metric
    ]
}
] //end of MetricList
} //end of response

```

The response has an `Identifier`, `AlignedStartTime`, and `AlignedEndTime`. Because the `--period-in-seconds` value was 60, the start and end times have been aligned to the minute. If the `--period-in-seconds` was 3600, the start and end times would have been aligned to the hour.

The `MetricList` in the response has a number of entries, each with a `Key` and a `DataPoints` entry. Each `DataProvider` has a `Timestamp` and a `Value`. Each `DataPoints` list has 60 data points because the queries are for per-minute data over an hour, with `Timestamp1/Minute1`, `Timestamp2/Minute2`, and so on, up to `Timestamp60/Minute60`.

Because the query is for two different counter metrics, there are two elements in the response `MetricList`.

Retrieving the DB load average for top wait events

The following example is the same query that the AWS Management Console uses to generate a stacked area line graph. This example retrieves the `db.load.avg` for the last hour with load divided according to the top seven wait events. The command is the same as the command in [Retrieving counter metrics \(p. 611\)](#). However, the `query.json` file has the following contents.

```

[
    {
        "Metric": "db.load.avg",
        "GroupBy": { "Group": "db.wait_event", "Limit": 7 }
    }
]

```

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries file://query.json
```

The example specifies the metric of db.load.avg and a GroupBy of the top seven wait events. For details about valid values for this example, see [DimensionGroup](#) in the *Performance Insights API Reference*.

The response looks similar to the following.

```
{
    "Identifier": "db-XXX",
    "AlignedStartTime": 1540857600.0,
    "AlignedEndTime": 1540861200.0,
    "MetricList": [
        { //A list of key/datapoints
            "Key": {
                //A Metric with no dimensions. This is the total db.load.avg
                "Metric": "db.load.avg"
            },
            "DataPoints": [
                //Each list of datapoints has the same timestamps and same number of items
                {
                    "Timestamp": 1540857660.0, //Minute1
                    "Value": 0.5166666666666667
                },
                {
                    "Timestamp": 1540857720.0, //Minute2
                    "Value": 0.3833333333333336
                },
                {
                    "Timestamp": 1540857780.0, //Minute 3
                    "Value": 0.2666666666666666
                }
                //... 60 datapoints for the total db.load.avg key
            ]
        },
        {
            "Key": {
                //Another key. This is db.load.avg broken down by CPU
                "Metric": "db.load.avg",
                "Dimensions": {
                    "db.wait_event.name": "CPU",
                    "db.wait_event.type": "CPU"
                }
            },
        }
    ]
}
```

```

    "DataPoints": [
        {
            "Timestamp": 1540857660.0, //Minute1
            "Value": 0.35
        },
        {
            "Timestamp": 1540857720.0, //Minute2
            "Value": 0.15
        },
        //... 60 datapoints for the CPU key
    ]
},
//... In total we have 8 key/datapoints entries, 1) total, 2-8) Top Wait Events
] //end of MetricList
} //end of response
}

```

In this response, there are eight entries in the `MetricList`. There is one entry for the total `db.load.avg`, and seven entries each for the `db.load.avg` divided according to one of the top seven wait events. Unlike in the first example, because there was a grouping dimension, there must be one key for each grouping of the metric. There can't be only one key for each metric, as in the basic counter metric use case.

Retrieving the DB load average for top SQL

The following example groups `db.wait_events` by the top 10 SQL statements. There are two different groups for SQL statements:

- `db.sql` – The full SQL statement, such as `select * from customers where customer_id = 123`
- `db.sql_tokenized` – The tokenized SQL statement, such as `select * from customers where customer_id = ?`

When analyzing database performance, it can be useful to consider SQL statements that only differ by their parameters as one logic item. So, you can use `db.sql_tokenized` when querying. However, especially when you're interested in explain plans, sometimes it's more useful to examine full SQL statements with parameters, and query grouping by `db.sql`. There is a parent-child relationship between tokenized and full SQL, with multiple full SQL (children) grouped under the same tokenized SQL (parent).

The command in this example is the similar to the command in [Retrieving the DB load average for top wait events \(p. 613\)](#). However, the `query.json` file has the following contents.

```
[
{
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.sql_tokenized", "Limit": 10 }
}
]
```

The following example uses `db.sql_tokenized`.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-29T00:00:00Z \
```

```
--end-time 2018-10-30T00:00:00Z \
--period-in-seconds 3600 \
--metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-29T00:00:00Z ^
--end-time 2018-10-30T00:00:00Z ^
--period-in-seconds 3600 ^
--metric-queries file://query.json
```

This example queries over 24 hours, with a one hour period-in-seconds.

The example specifies the metric of db.load.avg and a GroupBy of the top seven wait events. For details about valid values for this example, see [DimensionGroup](#) in the *Performance Insights API Reference*.

The response looks similar to the following.

```
{
    "AlignedStartTime": 1540771200.0,
    "AlignedEndTime": 1540857600.0,
    "Identifier": "db-XXX",

    "MetricList": [ //11 entries in the MetricList
        {
            "Key": { //First key is total
                "Metric": "db.load.avg"
            }
            "DataPoints": [ //Each DataPoints list has 24 per-hour Timestamps and a value
                {
                    "Value": 1.6964980544747081,
                    "Timestamp": 1540774800.0
                },
                //... 24 datapoints
            ]
        },
        {
            "Key": { //Next key is the top tokenized SQL
                "Dimensions": {
                    "db.sql_tokenized.statement": "INSERT INTO authors (id,name,email) VALUES\n( nextval(?) ,?,?)",
                    "db.sql_tokenized.db_id": "pi-2372568224",
                    "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE"
                },
                "Metric": "db.load.avg"
            },
            "DataPoints": [ //... 24 datapoints
            ]
        },
        // In total 11 entries, 10 Keys of top tokenized SQL, 1 total key
    ] //End of MetricList
} //End of response
```

This response has 11 entries in the MetricList (1 total, 10 top tokenized SQL), with each entry having 24 per-hour DataPoints.

For tokenized SQL, there are three entries in each dimensions list:

- `db.sql_tokenized.statement` – The tokenized SQL statement.
- `db.sql_tokenized.db_id` – Either the native database ID used to refer to the SQL, or a synthetic ID that Performance Insights generates for you if the native database ID isn't available. This example returns the `pi-2372568224` synthetic ID.
- `db.sql_tokenized.id` – The ID of the query inside Performance Insights.

In the AWS Management Console, this ID is called the Support ID. It's named this because the ID is data that AWS Support can examine to help you troubleshoot an issue with your database. AWS takes the security and privacy of your data extremely seriously, and almost all data is stored encrypted with your AWS KMS customer master key (CMK). Therefore, nobody inside AWS can look at this data. In the example preceding, both the `tokenized.statement` and the `tokenized.db_id` are stored encrypted. If you have an issue with your database, AWS Support can help you by referencing the Support ID.

When querying, it might be convenient to specify a Group in `GroupBy`. However, for finer-grained control over the data that's returned, specify the list of dimensions. For example, if all that is needed is the `db.sql_tokenized.statement`, then a `Dimensions` attribute can be added to the `query.json` file.

```
[  
  {  
    "Metric": "db.load.avg",  
    "GroupBy": {  
      "Group": "db.sql_tokenized",  
      "Dimensions": ["db.sql_tokenized.statement"],  
      "Limit": 10  
    }  
  }  
]
```

Retrieving the DB load average filtered by SQL

The preceding image shows that a particular query is selected, and the top average active sessions stacked area line graph is scoped to that query. Although the query is still for the top seven overall wait events, the value of the response is filtered. The filter causes it to take into account only sessions that are a match for the particular filter.

The corresponding API query in this example is similar to the command in [Retrieving the DB load average for top SQL \(p. 615\)](#). However, the query.json file has the following contents.

```
[  
 {  
     "Metric": "db.load.avg",  
     "GroupBy": { "Group": "db.wait_event", "Limit": 5 },  
     "Filter": { "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE" }  
 }  
]
```

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \  
  --service-type RDS \  
  --identifier db-ID \  
  --start-time 2018-10-30T00:00:00Z \  
  --end-time 2018-10-30T01:00:00Z \  
  --period-in-seconds 60 \  
  --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^  
  --service-type RDS ^  
  --identifier db-ID ^  
  --start-time 2018-10-30T00:00:00Z ^  
  --end-time 2018-10-30T01:00:00Z ^  
  --period-in-seconds 60 ^  
  --metric-queries file://query.json
```

The response looks similar to the following.

```
{  
    "Identifier": "db-XXX",  
    "AlignedStartTime": 1556215200.0,  
    "MetricList": [  
        {  
            "Key": {  
                "Metric": "db.load.avg"  
            },  
            "DataPoints": [  
                {  
                    "Timestamp": 1556218800.0,  
                    "Value": 1.4878117913832196  
                },  
                {  
                    "Timestamp": 1556222400.0,  
                    "Value": 1.192823803967328  
                }  
            ]  
        },  
        {

                "db.wait_event.name": "wait/synch/mutex/innodb/lock_wait_mutex"
            }
        },
        "DataPoints": [
            {
                "Timestamp": 1556218800.0,
                "Value": 0.017573696145124718
            },
            {
                "Timestamp": 1556222400.0,
                "Value": 0.002333722287047841
            }
        ]
    }
],
"AlignedEndTime": 1556222400.0
} //end of response

```

In this response, all values are filtered according to the contribution of tokenized SQL AKIAIOSFODNN7EXAMPLE specified in the query.json file. The keys also might follow a different order than a query without a filter, because it's the top five wait events that affected the filtered SQL.

Retrieving the full text of a SQL statement

The following example retrieves the full text of a SQL statement for DB instance db-10BCD2EFGHIJ3KL4M5NO6PQRS5. The --group is db.sql, and the --group-identifier is db.sql.id. In this example, *my-sql-id* represents a SQL ID retrieved by invoking pi get-resource-metrics or pi describe-dimension-keys.

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-dimension-key-details \
--service-type RDS \
--identifier db-10BCD2EFGHIJ3KL4M5NO6PQRS5 \
--group db.sql \
--group-identifier my-sql-id \
--requested-dimensions statement
```

For Windows:

```
aws pi get-dimension-key-details ^
--service-type RDS ^
--identifier db-10BCD2EFGHIJ3KL4M5NO6PQRS5 ^
--group db.sql ^
--group-identifier my-sql-id ^
--requested-dimensions statement
```

In this example, the dimensions details are available. Thus, Performance Insights retrieves the full text of the SQL statement, without truncating it.

```
{
```

```
"Dimensions": [
  {
    "Value": "SELECT e.last_name, d.department_name FROM employees e, departments d

```

Logging Performance Insights calls using AWS CloudTrail

Performance Insights runs with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Performance Insights. CloudTrail captures all API calls for Performance Insights as events. This capture includes calls from the Amazon RDS console and from code calls to the Performance Insights API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Performance Insights. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the data collected by CloudTrail, you can determine certain information. This information includes the request that was made to Performance Insights, the IP address the request was made from, who made the request, and when it was made. It also includes additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#).

Working with Performance Insights information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Performance Insights, that activity is recorded in a CloudTrail event along with other AWS service events in the CloudTrail console in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#) in *AWS CloudTrail User Guide*.

For an ongoing record of events in your AWS account, including events for Performance Insights, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in *AWS CloudTrail User Guide*:

- [Overview for Creating a Trail](#)
- [CloudTrail Supported Services and Integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)

All Performance Insights operations are logged by CloudTrail and are documented in the [Performance Insights API Reference](#). For example, calls to the `DescribeDimensionKeys` and `GetResourceMetrics` operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity Element](#).

Performance Insights log file entries

A *trail* is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An *event* represents a single request from any source. Each event includes information about the requested operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `GetResourceMetrics` operation.

```
{  
    "eventVersion": "1.05",  
    "userIdentity": {  
        "type": "IAMUser",  
        "principalId": "AKIAIOSFODNN7EXAMPLE",  
        "arn": "arn:aws:iam::123456789012:user/johndoe",  
        "accountId": "123456789012",  
        "accessKeyId": "AKIAI44QH8DHBEXAMPLE",

Analyzing performance anomalies with DevOps Guru for RDS

Amazon DevOps Guru is a fully managed operations service that helps developers and operators improve the performance and availability of their applications. DevOps Guru offloads the tasks associated with identifying operational issues so that you can quickly implement recommendations to improve your application. To learn more, see [What is Amazon DevOps Guru?](#) in the *Amazon DevOps Guru User Guide*.

DevOps Guru detects, analyzes, and makes recommendations for operational issues for all Amazon RDS DB engines. DevOps Guru for RDS extends this capability by applying machine learning to Performance Insights metrics for Amazon Aurora databases. These monitoring features allow DevOps Guru for RDS to detect and diagnose performance bottlenecks and recommend specific corrective actions. To learn more, see [Overview of DevOps Guru for RDS](#) in the *Amazon DevOps Guru User Guide*.

Topics

- [Benefits of DevOps Guru for RDS \(p. 623\)](#)
- [How DevOps Guru for RDS works \(p. 624\)](#)
- [Setting up DevOps Guru for RDS \(p. 624\)](#)

Benefits of DevOps Guru for RDS

If you're responsible for an Amazon Aurora database, you might not know that an event or regression that is affecting that database is occurring. When you learn about the issue, you might not know why it's occurring or what to do about it. Rather than turning to a database administrator (DBA) for help or relying on third-party tools, you can follow recommendations from DevOps Guru for RDS.

You gain the following advantages from the detailed analysis of DevOps Guru for RDS:

Fast diagnosis

DevOps Guru for RDS continuously monitors and analyzes database telemetry. Performance Insights, Enhanced Monitoring, and Amazon CloudWatch collect telemetry data for your database cluster. DevOps Guru for RDS uses statistical and machine learning techniques to mine this data and detect anomalies. To learn more about telemetry data, see [Monitoring DB load with Performance Insights on Amazon Aurora](#) and [Monitoring the OS by using Enhanced Monitoring](#) in the *Amazon Aurora User Guide*.

Fast resolution

Each anomaly identifies the performance issue and suggests avenues of investigation or corrective actions. For example, DevOps Guru for RDS might recommend that you investigate specific wait events. Or it might recommend that you tune your application pool settings to limit the number of database connections. Based on these recommendations, you can resolve performance issues more quickly than by troubleshooting manually.

Deep knowledge of Amazon engineers

To detect performance issues and help you resolve bottlenecks, DevOps Guru for RDS relies on machine learning (ML). Amazon database engineers contributed to the development of the DevOps Guru for RDS findings, which encapsulate many years of managing hundreds of thousands of databases. By drawing on this collective knowledge, DevOps Guru for RDS can teach you best practices.

How DevOps Guru for RDS works

DevOps Guru for RDS collects data about your Aurora databases from Amazon RDS Performance Insights. The most important metric is `DBLoad`. DevOps Guru for RDS consumes the Performance Insights metrics, analyzes them with machine learning, and publishes insights to the dashboard.

Insights

An *insight* is a collection of related anomalies that were detected by DevOps Guru. If DevOps Guru for RDS finds performance issues in your Amazon Aurora DB instances, it publishes an insight in the DevOps Guru dashboard. To learn more about insights, see [Working with insights in DevOps Guru](#) in the [Amazon DevOps Guru User Guide](#).

Anomalies

In DevOps Guru for RDS, an *anomaly* is a pattern that deviates from what is considered normal performance for your Amazon Aurora database.

Causal anomalies

A *causal anomaly* is a top-level anomaly within an insight. **Database load (DB load)** is the causal anomaly for DevOps Guru for RDS.

An anomaly measures performance impact by assigning a severity level of **High**, **Medium**, or **Low**. To learn more, see [Key concepts for DevOps Guru for RDS](#) in the [Amazon DevOps Guru User Guide](#).

If DevOps Guru detects an anomaly on your DB instance, you're alerted in the **Databases** page of the RDS console. To go to the anomaly page from the RDS console, choose the link in the alert message. The RDS console also alerts you in the page for your Amazon Aurora cluster.

Contextual anomalies

A *contextual anomaly* is a finding within **Database load (DB load)**. Each contextual anomaly describes a specific Amazon Aurora performance issue that requires investigation. For example, DevOps Guru for RDS might recommend that you consider increasing CPU capacity or investigate wait events that are contributing to DB load. [Amazon Aurora versions \(p. 5\)](#)

Important

We recommend that you test any changes on a test instance before modifying a production instance. In this way, you understand the impact of the change.

To learn more, see [Analyzing anomalies in Amazon Aurora clusters](#) in the [Amazon DevOps Guru User Guide](#).

Setting up DevOps Guru for RDS

To allow DevOps Guru for RDS to publish insights for an Amazon Aurora database, complete the following tasks.

Topics

- [Turning on Performance Insights for your Amazon Aurora DB instances \(p. 625\)](#)
- [Configuring access policies for DevOps Guru for RDS \(p. 625\)](#)
- [Adding Amazon Aurora resources to your DevOps Guru coverage \(p. 625\)](#)

Turning on Performance Insights for your Amazon Aurora DB instances

DevOps Guru for RDS relies on Performance Insights for its data. Without Performance Insights, DevOps Guru publishes anomalies, but doesn't include the detailed analysis and recommendations.

When you create or modify a DB instance, you can turn on Performance Insights. For more information, see [Enabling and disabling Performance Insights \(p. 577\)](#).

Configuring access policies for DevOps Guru for RDS

For your IAM user or role to access DevOps Guru for RDS, it must have either of the following policies:

- The AWS managed policy `AmazonRDSFullAccess`
- A customer managed policy that allows the following actions:
 - `pi:GetResourceMetrics`
 - `pi:DescribeDimensionKeys`
 - `pi:GetDimensionKeyDetails`

For more information, see [Configuring access policies for Performance Insights \(p. 582\)](#).

Adding Amazon Aurora resources to your DevOps Guru coverage

To set up DevOps Guru for the first time, perform the following steps:

1. Sign up to AWS if you aren't already signed up.
2. Determine coverage for your resources.

To allow DevOps Guru for RDS to generate anomalies for your Amazon Aurora DB instances, specify the instances that you want to be covered. By default, DevOps Guru analyzes all supported AWS resources in your AWS Region and account. You can also specify individual resources by using AWS CloudFormation stacks or applying tags. To learn more, see [Adding Amazon Aurora resources to your DevOps Guru coverage](#) in the *Amazon DevOps Guru User Guide*.

3. Identify Amazon SNS topics.

Use one or two Amazon SNS topics to generate notifications about important DevOps Guru for RDS events. An example is when an insight is created for an Amazon Aurora DB instance. In this way, you know about issues that DevOps Guru for RDS finds as soon as possible. To learn more, see [Identify your Amazon SNS notifications topic](#) in the *Amazon DevOps Guru User Guide*.

For more information, see [Setting up Amazon DevOps Guru](#) in the *Amazon DevOps Guru User Guide*.

Monitoring OS metrics with Enhanced Monitoring

With Enhanced Monitoring, you can monitor the operating system of your DB instance in real time. When you want to see how different processes or threads use the CPU, Enhanced Monitoring metrics are useful.

Topics

- [Overview of Enhanced Monitoring \(p. 626\)](#)
- [Setting up and enabling Enhanced Monitoring \(p. 627\)](#)
- [Viewing OS metrics in the RDS console \(p. 630\)](#)
- [Viewing OS metrics using CloudWatch Logs \(p. 632\)](#)

Overview of Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view all the system metrics and process information for your RDS DB instances on the console. You can manage which metrics you want to monitor for each instance and customize the dashboard according to your requirements.

RDS delivers the metrics from Enhanced Monitoring into your Amazon CloudWatch Logs account. You can create metrics filters in CloudWatch from CloudWatch Logs and display the graphs on the CloudWatch dashboard. You can consume the Enhanced Monitoring JSON output from CloudWatch Logs in a monitoring system of your choice. For more information, see [Enhanced Monitoring](#) in the Amazon RDS FAQs.

Topics

- [Differences between CloudWatch and Enhanced Monitoring metrics \(p. 626\)](#)
- [Retention of Enhanced Monitoring metrics \(p. 626\)](#)
- [Cost of Enhanced Monitoring \(p. 627\)](#)

Differences between CloudWatch and Enhanced Monitoring metrics

A *hypervisor* creates and runs virtual machines (VMs). Using a hypervisor, an instance can support multiple guest VMs by virtually sharing memory and CPU. CloudWatch gathers metrics about CPU utilization from the hypervisor for a DB instance. In contrast, Enhanced Monitoring gathers its metrics from an agent on the DB instance.

You might find differences between the CloudWatch and Enhanced Monitoring measurements, because the hypervisor layer performs a small amount of work. The differences can be greater if your DB instances use smaller instance classes. In this scenario, more virtual machines (VMs) are probably managed by the hypervisor layer on a single physical instance.

Retention of Enhanced Monitoring metrics

By default, Enhanced Monitoring metrics are stored for 30 days in the CloudWatch Logs. This retention period is different from typical CloudWatch metrics.

To modify the amount of time the metrics are stored in the CloudWatch Logs, change the retention for the `RDSOSMetrics` log group in the CloudWatch console. For more information, see [Change log data retention in CloudWatch logs](#) in the *Amazon CloudWatch Logs User Guide*.

Cost of Enhanced Monitoring

Enhanced Monitoring metrics are stored in the CloudWatch Logs instead of in CloudWatch metrics. The cost of Enhanced Monitoring depends on the following factors:

- You are charged for Enhanced Monitoring only if you exceed the free tier provided by Amazon CloudWatch Logs. Charges are based on CloudWatch Logs data transfer and storage rates.
- The amount of information transferred for an RDS instance is directly proportional to the defined granularity for the Enhanced Monitoring feature. A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost. To manage costs, set different granularities for different instances in your accounts.
- Usage costs for Enhanced Monitoring are applied for each DB instance that Enhanced Monitoring is enabled for. Monitoring a large number of DB instances is more expensive than monitoring only a few.
- DB instances that support a more compute-intensive workload have more OS process activity to report and higher costs for Enhanced Monitoring.

For more information about pricing, see [Amazon CloudWatch pricing](#).

Setting up and enabling Enhanced Monitoring

To use Enhanced Monitoring, you must create an IAM role, and then enable Enhanced Monitoring.

Topics

- [Creating an IAM role for Enhanced Monitoring \(p. 627\)](#)
- [Turning Enhanced Monitoring on and off \(p. 628\)](#)
- [Protecting against the confused deputy problem \(p. 630\)](#)

Creating an IAM role for Enhanced Monitoring

Enhanced Monitoring requires permission to act on your behalf to send OS metric information to CloudWatch Logs. You grant Enhanced Monitoring permissions using an AWS Identity and Access Management (IAM) role. You can either create this role when you enable Enhanced Monitoring or create it beforehand.

Topics

- [Creating the IAM role when you enable Enhanced Monitoring \(p. 627\)](#)
- [Creating the IAM role before you enable Enhanced Monitoring \(p. 628\)](#)

Creating the IAM role when you enable Enhanced Monitoring

When you enable Enhanced Monitoring in the RDS console, Amazon RDS can create the required IAM role for you. The role is named `rds-monitoring-role`. RDS uses this role for the specified DB instance or read replica.

To create the IAM role when enabling Enhanced Monitoring

1. Follow the steps in [Turning Enhanced Monitoring on and off \(p. 628\)](#).
2. Set **Monitoring Role** to **Default** in the step where you choose a role.

Creating the IAM role before you enable Enhanced Monitoring

You can create the required role before you enable Enhanced Monitoring. When you enable Enhanced Monitoring, specify your new role's name. You must create this required role if you enable Enhanced Monitoring using the AWS CLI or the RDS API.

The user that enables Enhanced Monitoring must be granted the `PassRole` permission. For more information, see Example 2 in [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

To create an IAM role for Amazon RDS enhanced monitoring

1. Open the [IAM console](#) at <https://console.aws.amazon.com>.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Choose the **AWS service** tab, and then choose **RDS** from the list of services.
5. Choose **RDS - Enhanced Monitoring**, and then choose **Next: Permissions**.
6. Ensure that the **Attached permissions policy** page shows **AmazonRDSEnhancedMonitoringRole**, and then choose **Next: Tags**.
7. On the **Add tags** page, choose **Next: Review**.
8. For **Role Name**, enter a name for your role. For example, enter **emaccess**.
The trusted entity for your role is the AWS service **monitoring.rds.amazonaws.com**.
9. Choose **Create role**.

Turning Enhanced Monitoring on and off

You can turn Enhanced Monitoring on and off using the AWS Management Console, AWS CLI, or RDS API. You choose the RDS DB instances on which you want to turn on Enhanced Monitoring. You can set different granularities for metric collection on each DB instance.

Console

You can enable Enhanced Monitoring when you create a DB cluster or read replica, or when you modify a DB cluster. If you modify a DB instance to enable Enhanced Monitoring, you don't need to reboot your DB instance for the change to take effect.

You can enable Enhanced Monitoring in the RDS console when you do one of the following actions in the **Databases** page:

- **Create a DB cluster** – Choose **Create database**.
- **Create a read replica** – Choose **Actions**, then **Create read replica**.
- **Modify a DB instance** – Choose **Modify**.

To turn Enhanced Monitoring on or off in the RDS console

1. Scroll to **Additional configuration**.
2. In **Monitoring**, choose **Enable Enhanced Monitoring** for your DB instance or read replica. To turn Enhanced Monitoring off, choose **Disable Enhanced Monitoring**.
3. Set the **Monitoring Role** property to the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose **Default** to have RDS create a role for you named `rds-monitoring-role`.

- Set the **Granularity** property to the interval, in seconds, between points when metrics are collected for your DB instance or read replica. The **Granularity** property can be set to one of the following values: 1, 5, 10, 15, 30, or 60.

Note

The fastest that the RDS console refreshes is every 5 seconds. If you set the granularity to 1 second in the RDS console, you still see updated metrics only every 5 seconds. You can retrieve 1-second metric updates by using CloudWatch Logs.

AWS CLI

To enable Enhanced Monitoring using the AWS CLI, in the following commands, set the `--monitoring-interval` option to a value other than 0 and set the `--monitoring-role-arn` option to the role you created in [Creating an IAM role for Enhanced Monitoring \(p. 627\)](#).

- `create-db-instance`
- `create-db-instance-read-replica`
- `modify-db-instance`

The `--monitoring-interval` option specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values for the option are 0, 1, 5, 10, 15, 30, and 60.

To turn off Enhanced Monitoring using the AWS CLI, set the `--monitoring-interval` option to 0 in these commands.

Example

The following example turn on Enhanced Monitoring for a DB instance:

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--monitoring-interval 30 \
--monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--monitoring-interval 30 ^
--monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

RDS API

To turn on Enhanced Monitoring using the RDS API, set the `MonitoringInterval` parameter to a value other than 0 and set the `MonitoringRoleArn` parameter to the role you created in [Creating an IAM role for Enhanced Monitoring \(p. 627\)](#). Set these parameters in the following actions:

- `CreateDBInstance`
- `CreateDBInstanceReadReplica`
- `ModifyDBInstance`

The `MonitoringInterval` parameter specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values are 0, 1, 5, 10, 15, 30, and 60.

To turn off Enhanced Monitoring using the RDS API, set `MonitoringInterval` to 0.

Protecting against the confused deputy problem

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see [The confused deputy problem](#).

To limit the permissions to the resource that Amazon RDS can give another service, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy for your Enhanced Monitoring role. If you use both global condition context keys, they must use the same account ID.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. For Amazon RDS, set `aws:SourceArn` to `arn:aws:rds:Region:my-account-id:db/dbname`.

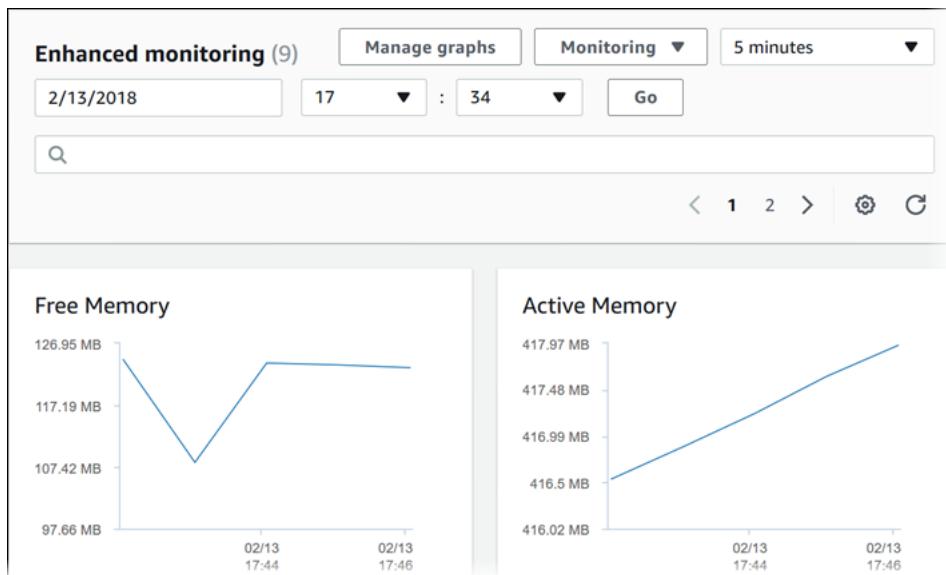

The following example uses the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in a trust policy to prevent the confused deputy problem.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "rds.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole",  
            "Condition": {  
                "StringLike": {  
                    "aws:SourceArn": "arn:aws:rds:Region:my-account-id:db/dbname"  
                },  
                "StringEquals": {  
                    "aws:SourceAccount": "my-account-id"  
                }  
            }  
        }  
    ]  
}
```

Viewing OS metrics in the RDS console

You can view OS metrics reported by Enhanced Monitoring in the RDS console by choosing **Enhanced monitoring for Monitoring**.

The Enhanced Monitoring page is shown following.

If you want to see details for the processes running on your DB instance, choose **OS process list** for **Monitoring**.

The **Process List** view is shown following.

Process List						
<input type="text"/> Filter process list						
NAME	VIRT	RES	CPU%	MEM%	VMLIMIT	
postgres [3181] ^t	283.55 MB	17.11 MB	0.02	1.72		
postgres: rdsadmin rdsadmin localhost(40156) idle [2953] ^t	384.7 MB	9.51 MB	0.02	0.95		

The Enhanced Monitoring metrics shown in the **Process list** view are organized as follows:

- **RDS child processes** – Shows a summary of the RDS processes that support the DB instance, for example `aurora` for Amazon Aurora DB clusters. Process threads appear nested beneath the parent process. Process threads show CPU utilization only as other metrics are the same for all threads for the process. The console displays a maximum of 100 processes and threads. The results are a combination of the top CPU consuming and memory consuming processes and threads. If there are more than 50 processes and more than 50 threads, the console displays the top 50 consumers in each category. This display helps you identify which processes are having the greatest impact on performance.
- **RDS processes** – Shows a summary of the resources used by the RDS management agent, diagnostics monitoring processes, and other AWS processes that are required to support RDS DB instances.
- **OS processes** – Shows a summary of the kernel and system processes, which generally have minimal impact on performance.

The items listed for each process are:

- **VIRT** – Displays the virtual size of the process.
- **RES** – Displays the actual physical memory being used by the process.
- **CPU%** – Displays the percentage of the total CPU bandwidth being used by the process.
- **MEM%** – Displays the percentage of the total memory being used by the process.

The monitoring data that is shown in the RDS console is retrieved from Amazon CloudWatch Logs. You can also retrieve the metrics for a DB instance as a log stream from CloudWatch Logs. For more information, see [Viewing OS metrics using CloudWatch Logs \(p. 632\)](#).

Enhanced Monitoring metrics are not returned during the following:

- A failover of the DB instance.
- Changing the instance class of the DB instance (scale compute).

Enhanced Monitoring metrics are returned during a reboot of a DB instance because only the database engine is rebooted. Metrics for the operating system are still reported.

Viewing OS metrics using CloudWatch Logs

After you have enabled Enhanced Monitoring for your DB instance, you can view the metrics for your DB instance using CloudWatch Logs, with each log stream representing a single DB instance being monitored. The log stream identifier is the resource identifier (`DbiResourceId`) for the DB instance.

To view Enhanced Monitoring log data

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. If necessary, choose the region that your DB instance is in. For more information, see [Regions and endpoints](#) in the *Amazon Web Services General Reference*.
3. Choose **Logs** in the navigation pane.
4. Choose **RDSOSMetrics** from the list of log groups.
5. Choose the log stream that you want to view from the list of log streams.

Metrics reference for Amazon Aurora

In this reference, you can find descriptions of Amazon Aurora metrics for Amazon CloudWatch, Performance Insights, and Enhanced Monitoring.

Topics

- [Amazon CloudWatch metrics for Amazon Aurora \(p. 633\)](#)
- [Amazon CloudWatch dimensions for Aurora \(p. 649\)](#)
- [Availability of Aurora metrics in the Amazon RDS console \(p. 649\)](#)
- [Amazon CloudWatch metrics for Performance Insights \(p. 652\)](#)
- [Performance Insights counter metrics \(p. 653\)](#)
- [OS metrics in Enhanced Monitoring \(p. 660\)](#)

Amazon CloudWatch metrics for Amazon Aurora

The AWS/RDS namespace includes the following metrics that apply to database entities running on Amazon Aurora. Some metrics apply to either Aurora MySQL, Aurora PostgreSQL, or both. Furthermore, some metrics are specific to a DB cluster, primary DB instance, replica DB instance, or all DB instances.

For Aurora global database metrics, see [Amazon CloudWatch metrics for write forwarding \(p. 263\)](#). For Aurora parallel query metrics, see [Monitoring parallel query \(p. 898\)](#).

Topics

- [Cluster-level metrics for Amazon Aurora \(p. 633\)](#)
- [Instance-level metrics for Amazon Aurora \(p. 639\)](#)

Cluster-level metrics for Amazon Aurora

The following table describes metrics that are specific to Aurora clusters.

Amazon Aurora cluster-level metrics

Metric	Console name	Description	Applies to	Units
AuroraGlobalDBDataTransferBytes	Aurora Global DB Data Transfer Bytes (Bytes)	In an Aurora Global Database, the amount of redo log data transferred from the master AWS Region to a secondary AWS Region.	Aurora MySQL and Aurora PostgreSQL	Bytes
AuroraGlobalDBProgressLag		In an Aurora Global Database, the measure of how far the secondary cluster is behind the primary cluster for both user transactions and system transactions.	Aurora PostgreSQL	Milliseconds
AuroraGlobalDBReplicatedWriteIO	Aurora Global DB Replicated Write IO	In an Aurora Global Database, the number of write I/O operations replicated from the	Aurora MySQL and Aurora PostgreSQL	Count

Metric	Console name	Description	Applies to	Units
		primary AWS Region to the cluster volume in a secondary AWS Region. The billing calculations for the secondary AWS Regions in a global database use VolumeWriteIOPS to account for writes performed within the cluster. The billing calculations for the primary AWS Region in a global database use VolumeWriteIOPS to account for the write activity within that cluster, and AuroraGlobalDBReplicatedWriteIO to account for cross-Region replication within the global database.		
AuroraGlobalDBReplicationLag	Aurora Global DB Replication Lag (Milliseconds)	For an Aurora Global Database, the amount of lag when replicating updates from the primary AWS Region.	Aurora MySQL and Aurora PostgreSQL	Milliseconds
AuroraGlobalDBRPOLag		In an Aurora Global Database, the recovery point objective (RPO) lag time. This metric measures how far the secondary cluster is behind the primary cluster for user transactions.	Aurora PostgreSQL	Milliseconds

Metric	Console name	Description	Applies to	Units
AuroraVolumeBytesLeftTotal		<p>The remaining available space for the cluster volume. As the cluster volume grows, this value decreases. If it reaches zero, the cluster reports an out-of-space error.</p> <p>If you want to detect whether your Aurora cluster is approaching the size limit of 128 tebibytes (TiB), this value is simpler and more reliable to monitor than VolumeBytesUsed. AuroraVolumeBytesLeftTotal takes into account storage used for internal housekeeping and other allocations that don't affect your storage billing.</p> <p>This parameter is available in more recent Aurora versions. For Aurora MySQL with MySQL 5.6 compatibility, use Aurora version 1.19.5 or higher. For Aurora MySQL with MySQL 5.7 compatibility, use Aurora version 2.04.5 or higher.</p>	Aurora MySQL	Bytes
BacktrackChangeRecordsCreated	Backtrack Change Records Creation Rate (Count)	The number of backtrack change records created over 5 minutes for your DB cluster.	Aurora MySQL	Count per 5 minutes
BacktrackChangeRecordsStored	Backtrack Change Records Stored (Count)	The number of backtrack change records used by your DB cluster.	Aurora MySQL	Count

Metric	Console name	Description	Applies to	Units
BackupRetentionPeriodStorageUsed	Backup Retention Period Storage Used (GiB)	The total amount of backup storage used to support the point-in-time restore feature within the Aurora DB cluster's backup retention window. This amount is included in the total reported by the <code>TotalBackupStorageBilled</code> metric. It is computed separately for each Aurora cluster. For instructions, see Understanding Aurora backup storage usage (p. 494) .	Aurora MySQL and Aurora PostgreSQL	Bytes
ServerlessDatabaseCapacity		The current capacity of an Aurora Serverless v1 DB cluster.	Aurora MySQL and Aurora PostgreSQL	Count
SnapshotStorageUsed	Snapshot Storage Used (GiB)	The total amount of backup storage consumed by all Aurora snapshots for an Aurora DB cluster outside its backup retention window. This amount is included in the total reported by the <code>TotalBackupStorageBilled</code> metric. It is computed separately for each Aurora cluster. For instructions, see Understanding Aurora backup storage usage (p. 494) .	Aurora MySQL and Aurora PostgreSQL	Bytes
TotalBackupStorageBilled	Total Backup Storage Used (GiB)	The total amount of backup storage in bytes for which you are billed for a given Aurora DB cluster. The metric includes the backup storage measured by the <code>BackupRetentionPeriodStorageUsed</code> and <code>SnapshotStorageUsed</code> metrics. This metric is computed separately for each Aurora cluster. For instructions, see Understanding Aurora backup storage usage (p. 494) .	Aurora MySQL and Aurora PostgreSQL	Bytes

Metric	Console name	Description	Applies to	Units
VolumeBytesUsed	Volume Bytes Used (GiB)	<p>The amount of storage used by your Aurora DB instance.</p> <p>This value affects the cost of the Aurora DB cluster (for pricing information, see the Amazon RDS product page).</p> <p>This value doesn't reflect some internal storage allocations that don't affect storage billing. Thus, you can anticipate out-of-space issues more accurately by testing whether <code>AuroraVolumeBytesLeftTotal</code> is approaching zero instead of comparing <code>VolumeBytesUsed</code> against the storage limit of 128 TiB.</p>	Aurora MySQL and Aurora PostgreSQL	Bytes

Metric	Console name	Description	Applies to	Units
VolumeReadIOPS	Volume Read IOPS (Count)	<p>The number of billed read I/O operations from a cluster volume within a 5-minute interval.</p> <p>Billed read operations are calculated at the cluster volume level, aggregated from all instances in the Aurora DB cluster, and then reported at 5-minute intervals. The value is calculated by taking the value of the Read operations metric over a 5-minute period. You can determine the amount of billed read operations per second by taking the value of the Billed read operations metric and dividing by 300 seconds. For example, if the Billed read operations returns 13,686, then the billed read operations per second is 45 ($13,686 / 300 = 45.62$).</p> <p>You accrue billed read operations for queries that request database pages that aren't in the buffer cache and must be loaded from storage. You might see spikes in billed read operations as query results are read from storage and then loaded into the buffer cache.</p> <p>Tip If your Aurora MySQL cluster uses parallel query, you might see an increase in VolumeReadIOPS values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing</p>	Aurora MySQL and Aurora PostgreSQL	Count per 5 minutes

Metric	Console name	Description	Applies to	Units
		can result in an increase in read operations and associated charges.		
VolumeWriteIOPS	Volume Write IOPS (Count)	The number of write disk I/O operations to the cluster volume, reported at 5-minute intervals. For a detailed description of how billed write operations are calculated, see VolumeReadIOPs .	Aurora MySQL and Aurora PostgreSQL	Count per 5 minutes

Instance-level metrics for Amazon Aurora

The following instance-specific CloudWatch metrics apply to all Aurora MySQL and Aurora PostgreSQL instances unless noted otherwise.

Amazon Aurora instance-level metrics

Metric	Console Name	Description	Applies to	Units
AbortedClients		The number of client connections that have not been closed properly.	Aurora MySQL	Count
ActiveTransactions	Active Transactions (Count)	The average number of current transactions executing on an Aurora database instance per second. By default, Aurora doesn't enable this metric. To begin measuring this value, set <code>innodb_monitor_enable='all'</code> in the DB parameter group for a specific DB instance.	Aurora MySQL	Count per second
AuroraBinlogReplicaLag	Aurora Binlog Replica Lag (Seconds)	The amount of time that a binary log replica DB cluster running on Aurora MySQL-Compatible Edition lags behind the binary log replication source. A lag means that the source is generating records faster than the replica can apply them.	Primary for Aurora MySQL	Seconds

Metric	Console Name	Description	Applies to	Units
		<p>This metric reports different values depending on the engine version:</p> <p>Aurora MySQL version 1 and 2</p> <pre>The Seconds_Behind_Master field of the MySQL SHOW SLAVE STATUS</pre> <p>Aurora MySQL version 3</p> <pre>SHOW REPLICA STATUS</pre> <p>You can use this metric to monitor errors and replica lag in a cluster that acts as a binary log replica. The metric value indicates the following:</p> <ul style="list-style-type: none"> A high value <ul style="list-style-type: none"> The replica is lagging the replication source. 0 or a value close to 0 The replica process is active and current. -1 Aurora can't determine the lag, which can happen during replica setup or when the replica is in an error state. Because binary log replication only occurs on the writer instance of the cluster, we recommend using the version of this metric associated with the WRITER role. For more information about administering replication, see Replicating Amazon Aurora MySQL DB clusters across AWS Regions (p. 922). 		

Metric	Console Name	Description	Applies to	Units
		For more information about troubleshooting, see Amazon Aurora MySQL replication issues (p. 1818) .		
AuroraReplicaLag	Aurora Replica Lag (Milliseconds)	For an Aurora replica, the amount of lag when replicating updates from the primary instance.	Replica for Aurora MySQL and Aurora PostgreSQL	Milliseconds
AuroraReplicaLagMaximum	Replica Lag Maximum (Milliseconds)	The maximum amount of lag between the primary instance and each Aurora DB instance in the DB cluster.	Primary for Aurora MySQL and Aurora PostgreSQL	Milliseconds
AuroraReplicaLagMinimum	Replica Lag Minimum (Milliseconds)	The minimum amount of lag between the primary instance and each Aurora DB instance in the DB cluster.	Primary for Aurora MySQL and Aurora PostgreSQL	Milliseconds
BacktrackWindowActual	Backtrack Window Actual (Minutes)	The difference between the target backtrack window and the actual backtrack window.	Primary for Aurora MySQL	Minutes
BacktrackWindowAlert	Backtrack Window Alert (Count)	The number of times that the actual backtrack window is smaller than the target backtrack window for a given period of time.	Primary for Aurora MySQL	Count
BlockedTransactions	Blocked Transactions (Count)	The average number of transactions in the database that are blocked per second.	Aurora MySQL	Count per second
BufferCacheHitRatio	Buffer Cache Hit Ratio (Percent)	The percentage of requests that are served by the buffer cache.	Aurora MySQL and Aurora PostgreSQL	Percentage
CommitLatency	Commit Latency (Milliseconds)	The average duration of commit operations.	Aurora MySQL and Aurora PostgreSQL	Milliseconds
CommitThroughput	Commit Throughput (Count/Second)	The average number of commit operations per second.	Aurora MySQL and Aurora PostgreSQL	Count per second

Metric	Console Name	Description	Applies to	Units
CPUCreditBalance	CPU Credit Balance (Count)	<p>The number of CPU credits that an instance has accumulated, reported at 5-minute intervals. You can use this metric to determine how long a DB instance can burst beyond its baseline performance level at a given rate.</p> <p>This metric applies only to db.t2.small and db.t2.medium instances for Aurora MySQL, and to db.t3 instances for Aurora PostgreSQL.</p>	Aurora MySQL and Aurora PostgreSQL	Count
CPUCreditUsage	CPU Credit Usage (Count)	<p>The number of CPU credits consumed during the specified period, reported at 5-minute intervals. This metric measures the amount of time during which physical CPUs have been used for processing instructions by virtual CPUs allocated to the DB instance.</p> <p>This metric applies only to db.t2.small and db.t2.medium instances for Aurora MySQL, and to db.t3 instances for Aurora PostgreSQL.</p>	Aurora MySQL and Aurora PostgreSQL	Count
CPUUtilization	CPU Utilization (Percent)	The percentage of CPU used by an Aurora DB instance.	Aurora MySQL and Aurora PostgreSQL	Percentage

Metric	Console Name	Description	Applies to	Units
DatabaseConnections	DB Connections (Count)	<p>The number of client network connections to the database instance.</p> <p>The number of database sessions can be higher than the metric value because the metric value doesn't include the following:</p> <ul style="list-style-type: none"> • Sessions that no longer have a network connection but which the database hasn't cleaned up • Sessions created by the database engine for its own purposes • Sessions created by the database engine's parallel execution capabilities • Sessions created by the database engine job scheduler • Amazon Aurora connections 	Aurora MySQL and Aurora PostgreSQL	Count
DDLLatency	DDL Latency (Milliseconds)	The average duration of requests such as example, create, alter, and drop requests.	Aurora MySQL	Milliseconds
DDLThroughput	DDL (Count/Second)	The average number of DDL requests per second.	Aurora MySQL	Count per second
Deadlocks	Deadlocks (Count)	The average number of deadlocks in the database per second.	Aurora MySQL and Aurora PostgreSQL	Count per second
DeleteLatency	Delete Latency (Milliseconds)	The average duration of delete operations.	Aurora MySQL	Milliseconds
DeleteThroughput	Delete Throughput (Count/Second)	The average number of delete queries per second.	Aurora MySQL	Count per second
DiskQueueDepth	Queue Depth (Count)	The number of outstanding read/write requests waiting to access the disk.	Aurora PostgreSQL	Count

Metric	Console Name	Description	Applies to	Units
DMLLatency	DML Latency (Milliseconds)	The average duration of inserts, updates, and deletes.	Aurora MySQL	Milliseconds
DMLThroughput	DML Throughput (Count/Second)	The average number of inserts, updates, and deletes per second.	Aurora MySQL	Count per second
EBSByteBalance%	EBS Byte Balance (Percent)	<p>The percentage of throughput credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only.</p> <p>To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in <i>Amazon EC2 User Guide for Linux Instances</i>. The Sum statistic is not applicable to this metric.</p>	Aurora MySQL and Aurora PostgreSQL	Percent
EBSIOBalance%	EBS IO Balance (Percent)	<p>The percentage of I/O credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only.</p> <p>To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in <i>Amazon EC2 User Guide for Linux Instances</i>. The Sum statistic is not applicable to this metric.</p> <p>This metric is different from <code>BurstBalance</code>. To learn how to use this metric, see Improving application performance and reducing costs with Amazon EBS-Optimized Instance burst capability.</p>	Aurora MySQL and Aurora PostgreSQL	Percent
EngineUptime	Engine Uptime (Seconds)	The amount of time that the instance has been running.	Aurora MySQL and Aurora PostgreSQL	Seconds

Metric	Console Name	Description	Applies to	Units
FreeableMemory	Freeable Memory (MB)	The amount of available random access memory.	Aurora MySQL and Aurora PostgreSQL	Bytes
FreeLocalStorage		<p>The amount of local storage available.</p> <p>Unlike for other DB engines, for Aurora DB instances this metric reports the amount of storage available to each DB instance. This value depends on the DB instance class (for pricing information, see the Amazon RDS product page). You can increase the amount of free storage space for an instance by choosing a larger DB instance class for your instance.</p>	Aurora MySQL and Aurora PostgreSQL	Bytes
InsertLatency	Insert Latency (Milliseconds)	The average duration of insert operations.	Aurora MySQL	Milliseconds
InsertThroughput	Insert Throughput (Count/Second)	The average number of insert operations per second.	Aurora MySQL	Count per second
LoginFailures	Login Failures (Count)	The average number of failed login attempts per second.	Aurora MySQL	Count per second
MaximumUsedTransactionID	MaximumUsedTransactionID	<p>Age of the oldest unvacuumed transaction ID, in transactions.</p> <p>If this value reaches 2,146,483,648 ($2^{31} - 1,000,000$), the database is forced into read-only mode, to avoid transaction ID wraparound. For more information, see Preventing transaction ID wraparound failures in the PostgreSQL documentation.</p>	Aurora PostgreSQL	Count

Metric	Console Name	Description	Applies to	Units
NetworkReceiveThroughput	Network Receive Throughput (MB/Second)	The amount of network throughput received from clients by each instance in the Aurora MySQL DB cluster. This throughput doesn't include network traffic between instances in the Aurora DB cluster and the cluster volume.	Aurora MySQL and Aurora PostgreSQL	Bytes per second (console shows Megabytes per second)
NetworkThroughput	Network Throughput (Byte/Second)	The amount of network throughput both received from and transmitted to clients by each instance in the Aurora MySQL DB cluster. This throughput doesn't include network traffic between instances in the DB cluster and the cluster volume.	Aurora MySQL and Aurora PostgreSQL	Bytes per second
NetworkTransmitThroughput	Network Transmit Throughput (MB/Second)	The amount of network throughput sent to clients by each instance in the Aurora DB cluster. This throughput doesn't include network traffic between instances in the DB cluster and the cluster volume.	Aurora MySQL and Aurora PostgreSQL	Bytes per second (console shows Megabytes per second)
NumBinaryLogFile		The number of binlog files generated.	Aurora MySQL	Count
Queries	Queries (Count/Second)	The average number of queries executed per second.	Aurora MySQL	Count per second
RDSToAuroraPostgreSQLReplicaLag		The lag when replicating updates from the primary RDS PostgreSQL instance to other nodes in the cluster.	Replica for Aurora PostgreSQL	Seconds
ReadIOPS	Read IOPS (Count/Second)	The average number of disk I/O operations per second. Aurora PostgreSQL-Compatible Edition reports read and write IOPS separately, in 1-minute intervals.	Aurora PostgreSQL	Count per second

Metric	Console Name	Description	Applies to	Units
ReadLatency	Read Latency (Milliseconds)	The average amount of time taken per disk I/O operation.	Aurora MySQL and Aurora PostgreSQL	Seconds
ReadThroughput	Read Throughput (MB/Second)	The average number of bytes read from disk per second.	Aurora PostgreSQL	Bytes per second
ReplicationSlotDiskUsage		The amount of disk space consumed by replication slot files.	Aurora PostgreSQL	Bytes
ResultSetCacheHitRatio	Result Set Cache Hit Ratio (Percent)	The percentage of requests that are served by the Resultset cache.	Aurora MySQL	Percentage
RollbackSegmentHistoryListLength		The undo logs that record committed transactions with delete-marked records. These records are scheduled to be processed by the InnoDB purge operation.	Aurora MySQL	Count
RowLockTime		The total time spent acquiring row locks for InnoDB tables.	Aurora MySQL	Milliseconds
SelectLatency	Select Latency (Milliseconds)	The average amount of time for select operations.	Aurora MySQL	Milliseconds
SelectThroughput	Select Throughput (Count/Second)	The average number of select queries per second.	Aurora MySQL	Count per second
StorageNetworkReceiveThroughput	Network Receive Throughput (MB/Second)	The amount of network throughput received from the Aurora storage subsystem by each instance in the DB cluster.	Aurora MySQL and Aurora PostgreSQL	Bytes per second
StorageNetworkThroughput	Network Throughput (Byte/Second)	The amount of network throughput received from and sent to the Aurora storage subsystem by each instance in the Aurora MySQL DB cluster.	Aurora MySQL and Aurora PostgreSQL	Bytes per second
StorageNetworkTransmitThroughput	Network Transmit Throughput (MB/Second)	The amount of network throughput sent to the Aurora storage subsystem by each instance in the Aurora MySQL DB cluster.	Aurora MySQL and Aurora PostgreSQL	Bytes per second
SumBinaryLogSize		The total size of the binlog files.	Aurora MySQL	Bytes

Metric	Console Name	Description	Applies to	Units
SwapUsage	Swap Usage (MB)	The amount of swap space used. This metric is available for the Aurora PostgreSQL DB instance classes db.t3.medium, db.t3.large, db.r4.large, db.r4.xlarge, db.r5.large, db.r5.xlarge, db.r6g.large, and db.r6g.xlarge. For Aurora MySQL, this metric applies only to db.t* DB instance classes.	Aurora MySQL and Aurora PostgreSQL	Bytes
TransactionLogsDiskUsage	Transaction Logs Disk Usage (MB)	The amount of disk space consumed by transaction logs on the Aurora PostgreSQL DB instance. This metric is generated only when Aurora PostgreSQL is using logical replication or AWS Database Migration Service. By default, Aurora PostgreSQL uses log records, not transaction logs. When transaction logs aren't in use, the value for this metric is -1.	Primary for Aurora PostgreSQL	Bytes
UpdateLatency	Update Latency (Milliseconds)	The average amount of time taken for update operations.	Aurora MySQL	Milliseconds
UpdateThroughput	Update Throughput (Count/Second)	The average number of updates per second.	Aurora MySQL	Count per second
WriteIOPS	Volume Write IOPS (Count)	The number of Aurora storage write records generated per second. This is more or less the number of log records generated by the database. These do not correspond to 8K page writes, and do not correspond to network packets sent.	Aurora PostgreSQL	Count per second
WriteLatency	Write Latency (Milliseconds)	The average amount of time taken per disk I/O operation.	Aurora MySQL and Aurora PostgreSQL	Seconds

Metric	Console Name	Description	Applies to	Units
WriteThroughput	Write Throughput (MB/Second)	The average number of bytes written to persistent storage every second.	Aurora PostgreSQL	Bytes per second

Amazon CloudWatch dimensions for Aurora

You can filter Aurora metrics data by using any dimension in the following table.

Dimension	Filters the requested data for . . .
DBInstanceIdentifier	A specific DB instance.
DBClusterIdentifier	A specific Amazon Aurora DB cluster.
DBClusterIdentifier, Role	A specific Aurora DB cluster, aggregating the metric by instance role (WRITER/READER). For example, you can aggregate metrics for all READER instances that belong to a cluster.
DatabaseClass	All instances in a database class. For example, you can aggregate metrics for all instances that belong to the database class db.r5.large.
EngineName	The identified engine name only. For example, you can aggregate metrics for all instances that have the engine name mysql.
SourceRegion	The specified Region only. For example, you can aggregate metrics for all DB instances in the us-east-1 Region.

Availability of Aurora metrics in the Amazon RDS console

Not all metrics provided by Amazon Aurora are available in the Amazon RDS console. You can view these metrics using tools such as the AWS CLI and CloudWatch API. Also, some metrics in the Amazon RDS console are either shown only for specific instance classes, or with different names and units of measurement.

Topics

- [Aurora metrics available in the Last Hour view \(p. 649\)](#)
- [Aurora metrics available in specific cases \(p. 650\)](#)
- [Aurora metrics that aren't available in the console \(p. 651\)](#)

Aurora metrics available in the Last Hour view

You can view a subset of categorized Aurora metrics in the default Last Hour view in the Amazon RDS console. The following table lists the categories and associated metrics displayed in the Amazon RDS console for an Aurora instance.

Category	Metrics
SQL	ActiveTransactions

Category	Metrics
	<pre>BlockedTransactions BufferCacheHitRatio CommitLatency CommitThroughput DatabaseConnections DDLLatency DDLTroughput Deadlocks DMILatency DMLThroughput LoginFailures ResultSetCacheHitRatio SelectLatency SelectThroughput</pre>
System	<pre>AuroraReplicaLag AuroraReplicaLagMaximum AuroraReplicaLagMinimum CPUCreditBalance CPUCreditUsage CPUUtilization FreeableMemory FreeLocalStorage NetworkReceiveThroughput</pre>
Deployment	<pre>AuroraReplicaLag BufferCacheHitRatio ResultSetCacheHitRatio SelectThroughput</pre>

Aurora metrics available in specific cases

In addition, some Aurora metrics are either shown only for specific instance classes, or only for DB instances, or with different names and different units of measurement:

- The `CPUCreditBalance` and `CPUCreditUsage` metrics are displayed only for Aurora MySQL `db.t2` instance classes and for Aurora PostgreSQL `db.t3` instance classes.
- The following metrics that are displayed with different names, as listed:

Metric	Display name
<code>AuroraReplicaLagMaximum</code>	Replica lag maximum
<code>AuroraReplicaLagMinimum</code>	Replica lag minimum
<code>DDLThroughput</code>	DDL
<code>NetworkReceiveThroughput</code>	Network throughput
<code>VolumeBytesUsed</code>	[Billed] Volume bytes used
<code>VolumeReadIOPS</code>	[Billed] Volume read IOPs
<code>VolumeWriteIOPS</code>	[Billed] Volume write IOPs

- The following metrics apply to an entire Aurora DB cluster, but are displayed only when viewing DB instances for an Aurora DB cluster in the Amazon RDS console:
 - `VolumeBytesUsed`
 - `VolumeReadIOPS`
 - `VolumeWriteIOPS`
- The following metrics are displayed in megabytes, instead of bytes, in the Amazon RDS console:
 - `FreeableMemory`
 - `FreeLocalStorage`
 - `NetworkReceiveThroughput`
 - `NetworkTransmitThroughput`

Aurora metrics that aren't available in the console

The following Aurora metrics aren't available in the Amazon RDS console:

- `AuroraBinlogReplicaLag`
- `DeleteLatency`
- `DeleteThroughput`
- `EngineUptime`
- `InsertLatency`
- `InsertThroughput`
- `NetworkThroughput`
- `Queries`
- `UpdateLatency`
- `UpdateThroughput`

Amazon CloudWatch metrics for Performance Insights

Performance Insights automatically publishes metrics to Amazon CloudWatch. The same data can be queried from Performance Insights, but having the metrics in CloudWatch makes it easy to add CloudWatch alarms. It also makes it easy to add the metrics to existing CloudWatch Dashboards.

Metric	Description
DBLoad	The number of active sessions for the DB engine. Typically, you want the data for the average number of active sessions. In Performance Insights, this data is queried as <code>db.load.avg</code> .
DBLoadCPU	The number of active sessions where the wait event type is CPU. In Performance Insights, this data is queried as <code>db.load.avg</code> , filtered by the wait event type CPU.
DBLoadNonCPU	The number of active sessions where the wait event type is not CPU.

Note

These metrics are published to CloudWatch only if there is load on the DB instance.

You can examine these metrics using the CloudWatch console, the AWS CLI, or the CloudWatch API.

For example, you can get the statistics for the `DBLoad` metric by running the [get-metric-statistics](#) command.

```
aws cloudwatch get-metric-statistics \
--region us-west-2 \
--namespace AWS/RDS \
--metric-name DBLoad \
--period 60 \
--statistics Average \
--start-time 1532035185 \
--end-time 1532036185 \
--dimensions Name=DBInstanceIdentifier,Value=db-loadtest-0
```

This example generates output similar to the following.

```
{
  "Datapoints": [
    {
      "Timestamp": "2021-07-19T21:30:00Z",
      "Unit": "None",
      "Average": 2.1
    },
    {
      "Timestamp": "2021-07-19T21:34:00Z",
      "Unit": "None",
      "Average": 1.7
    },
    {
      "Timestamp": "2021-07-19T21:35:00Z",
      "Unit": "None",
      "Average": 1.7
    }
  ]
}
```

```

    "Average": 2.8
  },
  {
    "Timestamp": "2021-07-19T21:31:00Z",
    "Unit": "None",
    "Average": 1.5
  },
  {
    "Timestamp": "2021-07-19T21:32:00Z",
    "Unit": "None",
    "Average": 1.8
  },
  {
    "Timestamp": "2021-07-19T21:29:00Z",
    "Unit": "None",
    "Average": 3.0
  },
  {
    "Timestamp": "2021-07-19T21:33:00Z",
    "Unit": "None",
    "Average": 2.4
  }
],
"Label": "DBLoad"
}

```

For more information about CloudWatch, see [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*.

Performance Insights counter metrics

Counter metrics are operating system and database performance metrics in the Performance Insights dashboard. To help identify and analyze performance problems, you can correlate counter metrics with DB load.

Topics

- [Performance Insights operating system counters \(p. 653\)](#)
- [Performance Insights counters for Aurora MySQL \(p. 655\)](#)
- [Performance Insights counters for Aurora PostgreSQL \(p. 659\)](#)

Performance Insights operating system counters

The following operating system counters are available with Performance Insights for Aurora PostgreSQL. You can find definitions for these metrics in [Viewing OS metrics using CloudWatch Logs \(p. 632\)](#).

Counter	Type	Metric
active	memory	os.memory.active
buffers	memory	os.memory.buffers
cached	memory	os.memory.cached
dirty	memory	os.memory.dirty
free	memory	os.memory.free
hugePagesFree	memory	os.memory.hugePagesFree

Counter	Type	Metric
hugePagesRsvd	memory	os.memory.hugePagesRsvd
hugePagesSize	memory	os.memory.hugePagesSize
hugePagesSurp	memory	os.memory.hugePagesSurp
hugePagesTotal	memory	os.memory.hugePagesTotal
inactive	memory	os.memory.inactive
mapped	memory	os.memory.mapped
pageTables	memory	os.memory.pageTables
slab	memory	os.memory.slab
total	memory	os.memory.total
writeback	memory	os.memory.writeback
guest	cpuUtilization	os.cpuUtilization.guest
idle	cpuUtilization	os.cpuUtilization.idle
irq	cpuUtilization	os.cpuUtilization.irq
nice	cpuUtilization	os.cpuUtilization.nice
steal	cpuUtilization	os.cpuUtilization.steal
system	cpuUtilization	os.cpuUtilization.system
total	cpuUtilization	os.cpuUtilization.total
user	cpuUtilization	os.cpuUtilization.user
wait	cpuUtilization	os.cpuUtilization.wait
avgQueueLen	diskIO	os.diskIO.avgQueueLen
avgReqSz	diskIO	os.diskIO.avgReqSz
await	diskIO	os.diskIO.await
readIOsPS	diskIO	os.diskIO.readIOsPS
readKb	diskIO	os.diskIO.readKb
readKbPS	diskIO	os.diskIO.readKbPS
rrqmPS	diskIO	os.diskIO.rrqmPS
tps	diskIO	os.diskIO.tps
util	diskIO	os.diskIO.util
writelOsPS	diskIO	os.diskIO.writelOsPS
writeKb	diskIO	os.diskIO.writeKb
writeKbPS	diskIO	os.diskIO.writeKbPS

Counter	Type	Metric
wrqmPS	diskIO	os.diskIO.wrqmPS
blocked	tasks	os.tasks.blocked
running	tasks	os.tasks.running
sleeping	tasks	os.tasks.sleeping
stopped	tasks	os.tasks.stopped
total	tasks	os.tasks.total
zombie	tasks	os.tasks.zombie
one	loadAverageMinute	os.loadAverageMinute.one
fifteen	loadAverageMinute	os.loadAverageMinute.fifteen
five	loadAverageMinute	os.loadAverageMinute.five
cached	swap	os.swap.cached
free	swap	os.swap.free
in	swap	os.swap.in
out	swap	os.swap.out
total	swap	os.swap.total
maxFiles	fileSys	os.fileSys.maxFiles
usedFiles	fileSys	os.fileSys.usedFiles
usedFilePercent	fileSys	os.fileSys.usedFilePercent
usedPercent	fileSys	os.fileSys.usedPercent
used	fileSys	os.fileSys.used
total	fileSys	os.fileSys.total
rx	network	os.network.rx
tx	network	os.network.tx
numVCPU	general	os.general.numVCPU

Performance Insights counters for Aurora MySQL

The following database counters are available with Performance Insights for Aurora MySQL.

Topics

- [Native counters for Aurora MySQL \(p. 656\)](#)
- [Non-native counters for Aurora MySQL \(p. 657\)](#)

Native counters for Aurora MySQL

You can find definitions for these native metrics in [Server Status Variables](#) in the MySQL documentation.

Counter	Type	Unit	Metric
Com_analyze	SQL	Queries per second	db.SQL.Com_analyze
Com_optimize	SQL	Queries per second	db.SQL.Com_optimize
Com_select	SQL	Queries per second	db.SQL.Com_select
Innodb_rows_deleted	SQL	Rows per second	db.SQL.Innodb_rows_deleted
Innodb_rows_inserted	SQL	Rows per second	db.SQL.Innodb_rows_inserted
Innodb_rows_read	SQL	Rows per second	db.SQL.Innodb_rows_read
Innodb_rows_updated	SQL	Rows per second	db.SQL.Innodb_rows_updated
Questions	SQL	Queries per second	db.SQL.Questions
Select_full_join	SQL	Queries per second	db.SQL.Select_full_join
Select_full_range_join	SQL	Queries per second	db.SQL.Select_full_range_join
Select_range	SQL	Queries per second	db.SQL.Select_range
Select_range_check	SQL	Queries per second	db.SQL.Select_range_check
Select_scan	SQL	Queries per second	db.SQL.Select_scan
Slow_queries	SQL	Queries per second	db.SQL.Slow_queries
Sort_merge_passes	SQL	Queries per second	db.SQL.Sort_merge_passes
Sort_range	SQL	Queries per second	db.SQL.Sort_range
Sort_rows	SQL	Queries per second	db.SQL.Sort_rows
Sort_scan	SQL	Queries per second	db.SQL.Sort_scan

Counter	Type	Unit	Metric
Table_locks_immediate	Locks	Requests per second	db.Locks.Table_locks_immediate
Table_locks_waited	Locks	Requests per second	db.Locks.Table_locks_waited
Innodb_row_lock_time	Locks	Milliseconds (average)	db.Locks.Innodb_row_lock_time
Aborted_clients	Users	Connections	db.Users.Aborted_clients
Aborted_connects	Users	Connections	db.Users.Aborted_connects
Threads_created	Users	Connections	db.Users.Threads_created
Threads_running	Users	Connections	db.Users.Threads_running
Created_tmp_disk_tables	Temp	Tables per second	db.Temp.Created_tmp_disk_tables
Created_tmp_tables	Temp	Tables per second	db.Temp.Created_tmp_tables
Innodb_buffer_pool_pages_data	Cache	Pages	db.Cache.Innodb_buffer_pool_pages_data
Innodb_buffer_pool_pages_total	Cache	Pages	db.Cache.Innodb_buffer_pool_pages_total
Innodb_buffer_pool_read_requests	Cache	Pages per second	db.Cache.Innodb_buffer_pool_read_requests
Innodb_buffer_pool_reads	Cache	Pages per second	db.Cache.Innodb_buffer_pool_reads
Opened_tables	Cache	Tables	db.Cache.Opened_tables
Opened_table_definitions	Cache	Tables	db.Cache.Opened_table_definitions
Qcache_hits	Cache	Queries	db.Cache.Qcache_hits

Non-native counters for Aurora MySQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

Counter	Type	Metric	Description	Definition
innodb_buffer_pool_hits	Cache	db.Cache.innodb_buffer_pool_hits	The buffer pool reads that InnoDB could satisfy from the buffer pool.	innodb_buffer_pool_read_requests - innodb_buffer_pool_reads
innodb_buffer_pool_hit_rate	Cache	db.Cache.innodb_buffer_pool_hit_rate	The percentage of reads that InnoDB could satisfy from the buffer pool.	100 * innodb_buffer_pool_read_requests / (innodb_buffer_pool_read_requests + innodb_buffer_pool_reads)

Counter	Type	Metric	Description	Definition
innodb_buffer_pool_usage	Cache	db.Cache.innodb_buffer_pool_usage	The percentage of the InnoDB buffer pool that contains data (pages). Note When using compressed tables, this value can vary. For more information, see the information about Innodb_buffer_pool_pages_data and Innodb_buffer_pool_pages_total in Server Status Variables in the MySQL documentation.	Innodb_buffer_pool_pages_data / Innodb_buffer_pool_pages_total * 100.0
query_cache_hit_rate	Cache	db.Cache.query_cache_hit_rate	The hit ratio for the MySQL result set cache (query cache).	Qcache_hits / (QCache_hits + Com_select) * 100
innodb_rows_changed	SQL	db.SQL.innodb_rows_changed	The total number of row operations.	db.SQL.Innodb_rows_inserted + db.SQL.Innodb_rows_deleted + db.SQL.Innodb_rows_updated
active_transactions	Transactions	db.Transactions.active_transactions	The total number of active transactions.	SELECT COUNT(1) AS active_transactions FROM INFORMATION_SCHEMA.INNODB_TRX
innodb_deadlocks	Locks	db.Lock.innodb_deadlocks	The total number of deadlocks.	SELECT COUNT AS innodb_deadlocks FROM INFORMATION_SCHEMA.INNODB_METR WHERE NAME='lock_deadlocks'
innodb_lock_timeouts	Locks	db.Lock.innodb_lock_timeouts	The total number of deadlocks that timed out.	SELECT COUNT AS innodb_lock_timeouts FROM INFORMATION_SCHEMA.INNODB_METR WHERE NAME='lock_timeouts'
innodb_row_lock_waits	Locks	db.Lock.innodb_row_lock_waits	The total number of row locks that resulted in a wait.	SELECT COUNT AS innodb_row_lock_waits FROM INFORMATION_SCHEMA.INNODB_METR WHERE NAME='lock_row_lock_waits'

Performance Insights counters for Aurora PostgreSQL

The following database counters are available with Performance Insights for Aurora PostgreSQL.

Topics

- [Native Counters for Aurora PostgreSQL \(p. 659\)](#)
- [Non-native counters for Aurora PostgreSQL \(p. 660\)](#)

Native Counters for Aurora PostgreSQL

You can find definitions for these native metrics in [Viewing Statistics](#) in the PostgreSQL documentation.

Counter	Type	Unit	Metric
tup_deleted	SQL	Tuples per second	db.SQL.tup_deleted
tup_fetched	SQL	Tuples per second	db.SQL.tup_fetched
tup_inserted	SQL	Tuples per second	db.SQL.tup_inserted
tup_returned	SQL	Tuples per second	db.SQL.tup_returned
tup_updated	SQL	Tuples per second	db.SQL.tup_updated
buffers_checkpoint	Checkpoint	Blocks per second	db.Checkpoint.buffers_checkpoint
checkpoints_req	Checkpoint	Checkpoints per minute	db.Checkpoint.checkpoints_req
checkpoint_sync_time	Checkpoint	Milliseconds per checkpoint	db.Checkpoint.checkpoint_sync_time
checkpoints_timed	Checkpoint	Checkpoints per minute	db.Checkpoint.checkpoints_timed
checkpoint_write_time	Checkpoint	Milliseconds per checkpoint	db.Checkpoint.checkpoint_write_time
maxwritten_clean	Checkpoint	Bgwriter clean stops per minute	db.Checkpoint.maxwritten_clean
active_transactions	Transactions	Transactions	db.Transactions.active_transactions
blocked_transactions	Transactions	Transactions	db.Transactions.blocked_transactions
max_used_xact_ids	Transactions	Transactions	db.Transactions.max_used_xact_ids
xact_commit	Transactions	Commits per second	db.Transactions.xact_commit
xact_rollback	Transactions	Rollbacks per second	db.Transactions.xact_rollback
blk_read_time	I/O	Milliseconds	db.IO.blk_read_time
blks_read	I/O	Blocks per second	db.IO.blks_read
buffers_backend	I/O	Blocks per second	db.IO.buffers_backend
buffers_backend_fsync	I/O	Blocks per second	db.IO.buffers_backend_fsync
buffers_clean	I/O	Blocks per second	db.IO.buffers_clean
blks_hit	Cache	Blocks per second	db.Cache.blks_hit

Counter	Type	Unit	Metric
buffers_alloc	Cache	Blocks per second	db.Cache.buffers_alloc
temp_files	Temp	Files per minute	db.Temp.temp_files
numbackends	User	Connections	db.User.numbackends
deadlocks	Concurrency	Deadlocks per minute	db.Concurrency.deadlocks
archived_count	WAL	Files per minute	db.WAL.archived_count
archive_failed_count	WAL	Files per minute	db.WAL.archive_failed_count

Non-native counters for Aurora PostgreSQL

Non-native counter metrics are counters defined by Amazon Aurora. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

Counter	Type	Metric	Description	Definition
checkpoint_sync_time	Checkpoint	db.Checkpoint.checkpoint_sync_time	The total time spent in milliseconds that has been spent in the portion of checkpoint processing where files are synchronized to disk.	checkpoint_sync_time / (checkpoints_timed + checkpoints_req)
checkpoint_write_time	Checkpoint	db.Checkpoint.checkpoint_write_time	The total time spent in milliseconds that has been spent in the portion of checkpoint processing where files are written to disk.	checkpoint_write_time / (checkpoints_timed + checkpoints_req)
read_latency	I/O	db.IO.read_latency	The time spent reading data file blocks by backends in this instance.	blk_read_time / blks_read

OS metrics in Enhanced Monitoring

Amazon Aurora provides metrics in real time for the operating system (OS) that your DB cluster runs on. Aurora delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. The following tables list the OS metrics available using Amazon CloudWatch Logs.

Topics

- [OS metrics for Aurora \(p. 661\)](#)

OS metrics for Aurora

Group	Metric	Console name	Description
General	engine	Not applicable	The database engine for the DB instance.
	instanceID	Not applicable	The DB instance identifier.
	instanceResID	Not applicable	An immutable identifier for the DB instance that is unique to an AWS Region, also used as the log stream identifier.
	numVCpus	Not applicable	The number of virtual CPUs for the DB instance.
	timestamp	Not applicable	The time at which the metrics were taken.
	uptime	Not applicable	The amount of time that the DB instance has been active.
	version	Not applicable	The version of the OS metrics' stream JSON format.
cpuUtilization	guest	CPU Guest	The percentage of CPU in use by guest programs.
	idle	CPU Idle	The percentage of CPU that is idle.
	irq	CPU IRQ	The percentage of CPU in use by software interrupts.
	nice	CPU Nice	The percentage of CPU in use by programs running at lowest priority.
	steal	CPU Steal	The percentage of CPU in use by other virtual machines.
	system	CPU System	The percentage of CPU in use by the kernel.
	total	CPU Total	The total percentage of the CPU in use. This value includes the nice value.
	user	CPU User	The percentage of CPU in use by user programs.
	wait	CPU Wait	The percentage of CPU unused while waiting for I/O access.
diskIO	avgQueueLen	Avg Queue Size	The number of requests waiting in the I/O device's queue.
	avgReqSz	Ave Request Size	The average request size, in kilobytes.
	await	Disk I/O Await	The number of milliseconds required to respond to requests, including queue time and service time.
	device	Not applicable	The identifier of the disk device in use.
	readIOsPS	Read IO/s	The number of read operations per second.

Group	Metric	Console name	Description
aurora_db_cluster	readKb	Read Total	The total number of kilobytes read.
	readKbPS	Read Kb/s	The number of kilobytes read per second.
	readLatency	Read Latency	The elapsed time between the submission of a read I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.
	readThroughput	Read Throughput	The amount of network throughput used by requests to the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.
	rrqmPS	Rrqms	The number of merged read requests queued per second.
	tps	TPS	The number of I/O transactions per second.
	util	Disk I/O Util	The percentage of CPU time during which requests were issued.
	writeIOsPS	Write IO/s	The number of write operations per second.
	writeKb	Write Total	The total number of kilobytes written.
	writeKbPS	Write Kb/s	The number of kilobytes written per second.
	writeLatency	Write Latency	The average elapsed time between the submission of a write I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.
	writeThroughput	Write Throughput	The amount of network throughput used by responses from the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.
	wrqmPS	Wrqms	The number of merged write requests queued per second.
fileSys	maxFiles	Max Inodes	The maximum number of files that can be created for the file system.
	mountPoint	Not applicable	The path to the file system.
	name	Not applicable	The name of the file system.
	total	Total Filesystem	The total number of disk space available for the file system, in kilobytes.
	used	Used Filesystem	The amount of disk space used by files in the file system, in kilobytes.
	usedFilePercent	Used %	The percentage of available files in use.
	usedFiles	Used Inodes	The number of files in the file system.

Group	Metric	Console name	Description
	usedPercent	Used Inodes %	The percentage of the file-system disk space in use.
loadAverage	fifteen	Load Avg 15 min	The number of processes requesting CPU time over the last 15 minutes.
	five	Load Avg 5 min	The number of processes requesting CPU time over the last 5 minutes.
	one	Load Avg 1 min	The number of processes requesting CPU time over the last minute.
memory	active	Active Memory	The amount of assigned memory, in kilobytes.
	buffers	Buffered Memory	The amount of memory used for buffering I/O requests prior to writing to the storage device, in kilobytes.
	cached	Cached Memory	The amount of memory used for caching file system-based I/O.
	dirty	Dirty Memory	The amount of memory pages in RAM that have been modified but not written to their related data block in storage, in kilobytes.
	free	Free Memory	The amount of unassigned memory, in kilobytes.
	hugePagesFree	Huge Pages Free	The number of free huge pages. Huge pages are a feature of the Linux kernel.
	hugePagesRsvd	Huge Pages Rsvd	The number of committed huge pages.
	hugePagesSz	Huge Pages Size	The size for each huge pages unit, in kilobytes.
	hugePagesSurp	Huge Pages Surp	The number of available surplus huge pages over the total.
	hugePagesTotal	Huge Pages Total	The total number of huge pages.
	inactive	Inactive Memory	The amount of least-frequently used memory pages, in kilobytes.
	mapped	Mapped Memory	The total amount of file-system contents that is memory mapped inside a process address space, in kilobytes.
	pageTables	Page Tables	The amount of memory used by page tables, in kilobytes.
	slab	Slab Memory	The amount of reusable kernel data structures, in kilobytes.
	total	Total Memory	The total amount of memory, in kilobytes.

Group	Metric	Console name	Description
	writeback	Writeback Memory	The amount of dirty pages in RAM that are still being written to the backing storage, in kilobytes.
network	interface	Not applicable	The identifier for the network interface being used for the DB instance.
	rx	RX	The number of bytes received per second.
	tx	TX	The number of bytes uploaded per second.
processList	cpuUsedPc	CPU %	The percentage of CPU used by the process.
	id	Not applicable	The identifier of the process.
	memoryUsedPmem%	MEM%	The percentage of memory used by the process.
	name	Not applicable	The name of the process.
	parentID	Not applicable	The process identifier for the parent process of the process.
	rss	RES	The amount of RAM allocated to the process, in kilobytes.
	tgid	Not applicable	The thread group identifier, which is a number representing the process ID to which a thread belongs. This identifier is used to group threads from the same process.
	vss	VIRT	The amount of virtual memory allocated to the process, in kilobytes.
swap	swap	Swap	The amount of swap memory available, in kilobytes.
	swap_in	Swaps in	The amount of memory, in kilobytes, swapped in from disk.
	swap_out	Swaps out	The amount of memory, in kilobytes, swapped out to disk.
	free	Free Swap	The amount of swap memory free, in kilobytes.
	committed	Committed Swap	The amount of swap memory, in kilobytes, used as cache memory.
tasks	blocked	Tasks Blocked	The number of tasks that are blocked.
	running	Tasks Running	The number of tasks that are running.
	sleeping	Tasks Sleeping	The number of tasks that are sleeping.
	stopped	Tasks Stopped	The number of tasks that are stopped.

Group	Metric	Console name	Description
	total	Tasks Total	The total number of tasks.
	zombie	Tasks Zombie	The number of child tasks that are inactive with an active parent task.

Monitoring events, logs, and streams in an Amazon Aurora DB cluster

When you monitor your Amazon Aurora databases and your other AWS solutions, your goal is to maintain the following:

- Reliability
- Availability
- Performance

[Monitoring metrics in an Amazon Aurora cluster \(p. 541\)](#) explains how to monitor your cluster using metrics. A complete solution must also monitor database events, log files, and activity streams. AWS provides you with the following monitoring tools:

- *Amazon EventBridge* is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, Software-as-a-Service (SaaS) applications, and AWS services and routes that data to targets such as AWS Lambda. This enables you to monitor events that happen in services, and build event-driven architectures. For more information, see the [Amazon EventBridge User Guide](#).
- *Amazon CloudWatch Logs* lets you monitor, store, and access your log files from Amazon Aurora instances, AWS CloudTrail, and other sources. Amazon CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the [Amazon CloudWatch Logs User Guide](#).
- *AWS CloudTrail* captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the [AWS CloudTrail User Guide](#).
- *Database Activity Streams* is an Amazon Aurora feature that provides a near-real-time stream of the activity in your DB cluster. Amazon Aurora pushes activities to an Amazon Kinesis data stream. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Topics

- [Viewing logs, events, and streams in the Amazon RDS console \(p. 666\)](#)
- [Monitoring Amazon Aurora events \(p. 671\)](#)
- [Monitoring Amazon Aurora log files \(p. 695\)](#)
- [Monitoring Amazon Aurora API calls in AWS CloudTrail \(p. 710\)](#)
- [Monitoring Amazon Aurora with Database Activity Streams \(p. 714\)](#)

Viewing logs, events, and streams in the Amazon RDS console

Amazon RDS integrates with AWS services to show information about logs, events, and database activity streams in the RDS console.

The **Logs & events** tab for your Aurora DB cluster shows the following information:

- **Auto scaling policies and activities** – Shows policies and activities relating to the Aurora Auto Scaling feature. This information only appears in the **Logs & events** tab at the cluster level.
- **Amazon CloudWatch alarms** – Shows any metric alarms that you have configured for the DB instance in your Aurora cluster. If you haven't configured alarms, you can create them in the RDS console.
- **Recent events** – Shows a summary of events (environment changes) for your Aurora DB instance or cluster. For more information, see [Viewing Amazon RDS events \(p. 674\)](#).
- **Logs** – Shows database log files generated by a DB instance in your Aurora cluster. For more information, see [Monitoring Amazon Aurora log files \(p. 695\)](#).

The **Configuration** tab displays information about database activity streams.

To view logs, events, and streams for your Aurora DB cluster in the RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the Aurora DB cluster that you want to monitor.

The database page appears. The following example shows an Amazon Aurora PostgreSQL DB cluster named apga.

The screenshot shows the Amazon RDS "Databases" page for the "apg" cluster. The cluster name "apg" is displayed prominently at the top. Below it, there is a "Related" section with a search bar labeled "Filter by databases". A table lists the cluster's components:

DB identifier	DB cluster identifier	Role	Engine
apg	apg	Regional cluster	Aurora PostgreSQL
apg-instance-1-us-east-1c	apg	Writer instance	Aurora PostgreSQL
apg-instance-1	apg	Reader instance	Aurora PostgreSQL
apg-instance-2	apg	Reader instance	Aurora PostgreSQL

At the bottom of the page, there are tabs for "Connectivity & security", "Monitoring", "Logs & events" (which is highlighted in orange), "Configuration", "Maintenance & backups", and "Tags".

4. Scroll down and choose **Configuration**.

The following example shows the status of the database activity streams for your cluster.

Configuration	Maintenance & backups	Tags
Availability	Encryption	
IAM DB authentication	Encryption	
Not enabled	Enabled	
Master username	AWS KMS key	
apga_admin	aws/rds 	
Master password	Database activity stream	
*****	Status	
Multi-AZ	Stopped	
3 Zones	Published logs	
	CloudWatch Logs	
	PostgreSQL	

5. Choose **Logs & events**.

The Logs & events section appears.

The screenshot shows the 'Logs & events' tab selected in the navigation bar. It displays three main sections:

- Auto scaling policies (0)**: A table with columns for Name, Scaling action, Target metric, and Target value. It includes a search bar, pagination, and buttons for Edit, Delete, and Add.
- Auto scaling activities (0)**: A table with columns for Start time, End time, Status, Description, and Status message. It includes a search bar, pagination, and a button for Add auto scaling policy.
- Recent events (3)**: A table with columns for Time and System notes. It includes a search bar, pagination, and a button for Filter by db events.

6. Choose a DB instance in your Aurora cluster, and then choose **Logs & events** for the instance.

The following example shows that the contents are different between the DB instance page and the DB cluster page. The DB instance page shows logs and alarms.

Amazon Aurora User Guide for Aurora
Viewing logs, events, and streams
in the Amazon RDS console

The screenshot shows the 'Logs & events' tab selected in the navigation bar. The interface is divided into three main sections: 'CloudWatch alarms', 'Recent events', and 'Logs'.

CloudWatch alarms (0): This section includes a search bar, a 'Create alarm' button, and a table header for 'Name' and 'State'. Below the table, it says 'Empty alarms table' and has a 'Create alarm' button.

Recent events (0): This section includes a search bar, a 'Create' button, and a table header for 'Time' and 'System notes'. Below the table, it says 'No events found.'

Logs (29): This section includes a search bar, buttons for 'View', 'Watch', and 'Download', and a table header for 'Name' and 'Last written'. The table lists three log files:

Name	Last written	Logs
error/postgres.log	Thu Feb 03 2022 12:18:27 GMT-0500	29.1 kB
error/postgresql.log.2022-02-03-1709	Thu Feb 03 2022 12:09:59 GMT-0500	4.3 kB
error/postgresql.log.2022-02-03-1710	Thu Feb 03 2022 12:10:58 GMT-0500	5.4 kB

Monitoring Amazon Aurora events

An *event* indicates a change in an environment. This can be an AWS environment, an SaaS partner service or application, or a custom application or service.

Topics

- [Overview of events for Aurora \(p. 671\)](#)
- [Viewing Amazon RDS events \(p. 674\)](#)
- [Using Amazon RDS event notification \(p. 675\)](#)
- [Creating a rule that triggers on an Amazon Aurora event \(p. 692\)](#)

Overview of events for Aurora

An *RDS event* indicates a change in the Aurora environment. For example, Amazon Aurora generates an event when a DB cluster is patched. Amazon Aurora delivers events to CloudWatch Events and EventBridge in near-real time.

Note

Amazon RDS emits events on a best effort basis. We recommend that you avoid writing programs that depend on the order or existence of notification events, because they might be out of sequence or missing.

Amazon RDS records events that relate to your DB clusters, DB instances, DB cluster snapshots, and DB parameter groups. This information includes the following:

- The date and time of the event
- The source name and source type of the event
- A message associated with the event.

The following examples illustrate different types of Aurora events.

Topics

- [Example of a DB cluster event \(p. 671\)](#)
- [Example of a DB instance event \(p. 672\)](#)
- [Example of a DB parameter group event \(p. 672\)](#)
- [Example of a DB cluster snapshot event \(p. 673\)](#)

Example of a DB cluster event

The following is an example of a DB cluster event in JSON format. The event shows that the cluster named `my-db-cluster` was patched. The event ID is `RDS-EVENT-0173`.

```
{  
    "version": "0",  
    "id": "844e2571-85d4-695f-b930-0153b71dcb42",  
    "detail-type": "RDS DB Cluster Event",  
    "source": "aws.rds",  
    "account": "123456789012",  
    "time": "2018-10-06T12:26:13Z",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:rds:us-east-1:123456789012:cluster:my-db-cluster"  
    ],  
}
```

```

    "detail": {
        "EventCategories": [
            "notification"
        ],
        "SourceType": "CLUSTER",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:my-db-cluster",
        "Date": "2018-10-06T12:26:13.882Z",
        "Message": "Database cluster has been patched",
        "SourceIdentifier": "rds:my-db-cluster",
        "EventID": "RDS-EVENT-0173"
    }
}

```

Example of a DB instance event

The following is an example of a DB instance event in JSON format. The event shows that RDS performed a multi-AZ failover for the instance named `my-db-instance`. The event ID is `RDS-EVENT-0049`.

```

{
    "version": "0",
    "id": "68f6e973-1a0c-d37b-f2f2-94a7f62ffd4e",
    "detail-type": "RDS DB Instance Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-09-27T22:36:43Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:db:my-db-instance"
    ],
    "detail": {
        "EventCategories": [
            "failover"
        ],
        "SourceType": "DB_INSTANCE",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:my-db-instance",
        "Date": "2018-09-27T22:36:43.292Z",
        "Message": "A Multi-AZ failover has completed.",
        "SourceIdentifier": "rds:my-db-instance",
        "EventID": "RDS-EVENT-0049"
    }
}

```

Example of a DB parameter group event

The following is an example of a DB parameter group event in JSON format. The event shows that the parameter `time_zone` was updated in parameter group `my-db-param-group`. The event ID is `RDS-EVENT-0037`.

```

{
    "version": "0",
    "id": "844e2571-85d4-695f-b930-0153b71dcba2",
    "detail-type": "RDS DB Parameter Group Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group"
    ],
    "detail": {

```

```
    "EventCategories": [
        "configuration change"
    ],
    "SourceType": "DB_PARAM",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group",
    "Date": "2018-10-06T12:26:13.882Z",
    "Message": "Updated parameter time_zone to UTC with apply method immediate",
    "SourceIdentifier": "rds:my-db-param-group",
    "EventID": "RDS-EVENT-0037"
}
}
```

Example of a DB cluster snapshot event

The following is an example of a DB cluster snapshot event in JSON format. The event shows the creation of the snapshot named my-db-cluster-snapshot. The event ID is RDS-EVENT-0074.

```
{
    "version": "0",
    "id": "844e2571-85d4-695f-b930-0153b71dcba2",
    "detail-type": "RDS DB Cluster Snapshot Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:cluster-snapshot:rds:my-db-cluster-snapshot"
    ],
    "detail": {
        "EventCategories": [
            "backup"
        ],
        "SourceType": "CLUSTER_SNAPSHOT",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:cluster-snapshot:rds:my-db-cluster-snapshot",
        "Date": "2018-10-06T12:26:13.882Z",
        "SourceIdentifier": "rds:my-db-cluster-snapshot",
        "Message": "Creating manual cluster snapshot",
        "EventID": "RDS-EVENT-0074"
    }
}
```

Viewing Amazon RDS events

You can retrieve events for your RDS resources through the AWS Management Console, which shows events from the past 24 hours. You can also retrieve events for your RDS resources by using the [describe-events](#) AWS CLI command, or the [DescribeEvents](#) RDS API operation. If you use the AWS CLI or the RDS API to view events, you can retrieve events for up to the past 14 days.

Note

If you need to store events for longer periods of time, you can send Amazon RDS events to CloudWatch Events. For more information, see [Creating a rule that triggers on an Amazon Aurora event \(p. 692\)](#)

Console

To view all Amazon RDS instance events for the past 24 hours

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Events**. The available events appear in a list.
3. Use the **Filter** list to filter the events by type, and use the text box to the right of the **Filter** list to further filter your results. For example, the following screenshot shows a list of events filtered by the characters **error**.

Name	Last written	Logs
error/mysql-error-running.log	Fri Dec 10 2021 12:30:00 GMT-0500	72.3 kB
error/mysql-error.log	Fri Dec 10 2021 12:36:40 GMT-0500	14.9 kB

AWS CLI

You can view all Amazon RDS instance events for the past 7 days by calling the [describe-events](#) AWS CLI command and setting the `--duration` parameter to 10080.

```
aws rds describe-events --duration 10080
```

API

You can view all Amazon RDS instance events for the past 14 days by calling the [DescribeEvents](#) RDS API operation and setting the `Duration` parameter to 20160.

Using Amazon RDS event notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint.

Topics

- [Listing the Amazon RDS event notification categories \(p. 690\)](#)
- [Deleting an Amazon RDS event notification subscription \(p. 691\)](#)

Overview of Amazon RDS event notification

Amazon RDS groups events into categories that you can subscribe to so that you can be notified when an event in that category occurs. Amazon RDS event notification is only available for unencrypted SNS topics. If you specify an encrypted SNS topic, event notifications aren't sent for the topic.

RDS resources eligible for event subscription

For Amazon Aurora, events occur at both the DB cluster and the DB instance level. You can subscribe to an event category for the following resources:

- DB instance
- DB cluster
- DB cluster snapshot
- DB parameter group
- DB security group
- RDS Proxy

For example, if you subscribe to the backup category for a given DB instance, you're notified whenever a backup-related event occurs that affects the DB instance. If you subscribe to a configuration change category for a DB security group, you're notified when the DB security group is changed. You also receive notification when an event notification subscription changes.

You might want to create several different subscriptions. For example, you might create one subscription receiving all event notifications and another subscription that includes only critical events for your production DB instances.

Basic process for subscribing to Amazon RDS event notifications

The process for subscribing to Amazon RDS event notification is as follows:

1. You create an Amazon RDS event notification subscription by using the Amazon RDS console, AWS CLI, or API.

Amazon RDS uses the ARN of an Amazon SNS topic to identify each subscription. The Amazon RDS console creates the ARN for you when you create the subscription. Create the ARN by using the Amazon SNS console, the AWS CLI, or the Amazon SNS API.

2. Amazon RDS sends an approval email or SMS message to the addresses you submitted with your subscription. To confirm your subscription, choose the link in the notification you were sent.
3. When you have confirmed the subscription, the status of your subscription is updated in the Amazon RDS console's **My Event Subscriptions** section.
4. You then begin to receive event notifications.

To learn about identity and access management when using Amazon SNS, see [Identity and access management in Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide*.

You can use AWS Lambda to process event notifications from a DB instance. For more information, see [Using AWS Lambda with Amazon RDS](#) in the *AWS Lambda Developer Guide*.

Delivery of RDS event notifications

Amazon RDS sends notifications to the addresses that you provide when you create the subscription. Event notifications might take up to five minutes to be delivered.

Important

Amazon RDS doesn't guarantee the order of events sent in an event stream. The event order is subject to change.

When Amazon SNS sends a notification to a subscribed HTTP or HTTPS endpoint, the POST message sent to the endpoint has a message body that contains a JSON document. For more information, see [Amazon SNS message and JSON formats](#) in the *Amazon Simple Notification Service Developer Guide*.

You can configure SNS to notify you with text messages. For more information, see [Mobile text messaging \(SMS\)](#) in the *Amazon Simple Notification Service Developer Guide*.

To turn off notifications without deleting a subscription, choose **No** for **Enabled** in the Amazon RDS console. Or you can set the `Enabled` parameter to `false` using the AWS CLI or Amazon RDS API.

Billing for Amazon RDS event notifications

Billing for Amazon RDS event notification is through Amazon SNS. Amazon SNS fees apply when using event notification. For more information about Amazon SNS billing, see [Amazon Simple Notification Service pricing](#).

Amazon RDS event categories and event messages

Amazon RDS generates a significant number of events in categories that you can subscribe to using the Amazon RDS Console, AWS CLI, or the API. Each category applies to a source type.

Topics

- [DB instance events \(p. 677\)](#)
- [DB parameter group events \(p. 679\)](#)
- [DB security group events \(p. 680\)](#)
- [DB cluster events \(p. 680\)](#)
- [DB cluster snapshot events \(p. 682\)](#)
- [RDS Proxy events \(p. 682\)](#)

DB instance events

The following table shows the event category and a list of events when a DB instance is the source type.

Category	Amazon RDS event ID	Description
Availability	RDS-EVENT-0006	The DB instance restarted.
Availability	RDS-EVENT-0004	DB instance shutdown.
Availability	RDS-EVENT-0022	An error has occurred while restarting Aurora MySQL or MariaDB.
Backtrack	RDS-EVENT-0131	The actual Backtrack window is smaller than the target Backtrack window you specified. Consider reducing the number of hours in your target Backtrack window. For more information about backtracking, see Backtracking an Aurora DB cluster (p. 816) .
Backtrack	RDS-EVENT-0132	The actual Backtrack window is the same as the target Backtrack window.
Configuration change	RDS-EVENT-0009	The DB instance has been added to a security group.
Configuration change	RDS-EVENT-0012	Applying modification to database instance class.
Configuration change	RDS-EVENT-0011	A parameter group for this DB instance has changed.
Configuration change	RDS-EVENT-0092	A parameter group for this DB instance has finished updating.
Configuration change	RDS-EVENT-0033	There are [count] users that match the master user name. Users not tied to a specific host have been reset.
Configuration change	RDS-EVENT-0025	The DB instance has been converted to a Multi-AZ DB instance.
Configuration change	RDS-EVENT-0029	The DB instance has been converted to a Single-AZ DB instance.
Configuration change	RDS-EVENT-0014	The DB instance class for this DB instance has changed.
Configuration change	RDS-EVENT-0017	The storage settings for this DB instance have changed.
Configuration change	RDS-EVENT-0010	The DB instance has been removed from a security group.
Configuration change	RDS-EVENT-0016	The master password for the DB instance has been reset.
Configuration change	RDS-EVENT-0067	An attempt to reset the master password for the DB instance has failed.

Category	Amazon RDS event ID	Description
Configuration change	RDS-EVENT-0078	The Enhanced Monitoring configuration has been changed.
Creation	RDS-EVENT-0005	DB instance created.
Deletion	RDS-EVENT-0003	The DB instance has been deleted.
Failure	RDS-EVENT-0035	The DB instance has invalid parameters. For example, if the DB instance could not start because a memory-related parameter is set too high for this instance class, the customer action would be to modify the memory parameter and reboot the DB instance.
Failure	RDS-EVENT-0036	The DB instance is in an incompatible network. Some of the specified subnet IDs are invalid or do not exist.
Failure	RDS-EVENT-0079	Enhanced Monitoring cannot be enabled without the enhanced monitoring IAM role. For information on creating the enhanced monitoring IAM role, see To create an IAM role for Amazon RDS enhanced monitoring (p. 628) .
Failure	RDS-EVENT-0080	Enhanced Monitoring was disabled due to an error making the configuration change. It is likely that the enhanced monitoring IAM role is configured incorrectly. For information on creating the enhanced monitoring IAM role, see To create an IAM role for Amazon RDS enhanced monitoring (p. 628) .
Failure	RDS-EVENT-0082	Aurora was unable to copy backup data from an Amazon S3 bucket. It is likely that the permissions for Aurora to access the Amazon S3 bucket are configured incorrectly. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 784) .
Low storage	RDS-EVENT-0007	The allocated storage for the DB instance has been consumed. To resolve this issue, allocate additional storage for the DB instance. For more information, see the RDS FAQ . You can monitor the storage space for a DB instance using the Free Storage Space metric.
Low storage	RDS-EVENT-0089	The DB instance has consumed more than 90% of its allocated storage. You can monitor the storage space for a DB instance using the Free Storage Space metric.
Maintenance	RDS-EVENT-0026	Offline maintenance of the DB instance is taking place. The DB instance is currently unavailable.
Maintenance	RDS-EVENT-0027	Offline maintenance of the DB instance is complete. The DB instance is now available.
Maintenance	RDS-EVENT-0047	Patching of the DB instance has completed.

Category	Amazon RDS event ID	Description
Maintenance	RDS-EVENT-0155	The DB instance has a DB engine minor version upgrade available.
Notification	RDS-EVENT-0044	Operator-issued notification. For more information, see the event message.
Notification	RDS-EVENT-0048	Patching of the DB instance has been delayed.
Read replica	RDS-EVENT-0045	An error has occurred in the read replication process. For more information, see the event message. For information on troubleshooting read replica errors, see Troubleshooting a MySQL read replica problem .
Read replica	RDS-EVENT-0046	The read replica has resumed replication. This message appears when you first create a read replica, or as a monitoring message confirming that replication is functioning properly. If this message follows an RDS-EVENT-0045 notification, then replication has resumed following an error or after replication was stopped.
Read replica	RDS-EVENT-0057	Replication on the read replica was terminated.
Recovery	RDS-EVENT-0020	Recovery of the DB instance has started. Recovery time will vary with the amount of data to be recovered.
Recovery	RDS-EVENT-0021	Recovery of the DB instance is complete.
Recovery	RDS-EVENT-0023	A manual backup has been requested but Amazon RDS is currently in the process of creating a DB snapshot. Submit the request again after Amazon RDS has completed the DB snapshot.
Recovery	RDS-EVENT-0052	Recovery of the Multi-AZ instance has started. Recovery time will vary with the amount of data to be recovered.
Recovery	RDS-EVENT-0053	Recovery of the Multi-AZ instance is complete.
Restoration	RDS-EVENT-0019	The DB instance has been restored from a point-in-time backup.
Restoration	RDS-EVENT-0043	Restored from snapshot [snapshot_name]. The DB instance has been restored from a DB snapshot.

DB parameter group events

The following table shows the event category and a list of events when a DB parameter group is the source type.

Category	RDS event ID	Description
Configuration change	RDS-EVENT-0037	The parameter group was modified.

DB security group events

The following table shows the event category and a list of events when a DB security group is the source type.

Category	RDS event ID	Description
Configuration change	RDS-EVENT-0038	The security group has been modified.
Failure	RDS-EVENT-0039	The security group owned by [user] does not exist; authorization for the security group has been revoked.

DB cluster events

The following table shows the event category and a list of events when an Aurora DB cluster is the source type.

Note

No event category exists for Aurora Serverless in the DB cluster event type. The Aurora Serverless events range from RDS-EVENT-0141 to RDS-EVENT-0149.

Category	RDS event ID	Description
Configuration change	RDS-EVENT-0179	Database Activity Streams is started on your database cluster. For more information see Monitoring Amazon Aurora with Database Activity Streams (p. 714) .
Configuration change	RDS-EVENT-0180	Database Activity Streams is stopped on your database cluster. For more information see Monitoring Amazon Aurora with Database Activity Streams (p. 714) .
creation	RDS-EVENT-0170	DB cluster created.
deletion	RDS-EVENT-0171	DB cluster deleted.
Failover	RDS-EVENT-0069	A failover for the DB cluster has failed.
Failover	RDS-EVENT-0070	A failover for the DB cluster has restarted.
Failover	RDS-EVENT-0071	A failover for the DB cluster has finished.
Failover	RDS-EVENT-0072	A failover for the DB cluster has begun within the same Availability Zone.
Failover	RDS-EVENT-0073	A failover for the DB cluster has begun across Availability Zones.

Category	RDS event ID	Description
Failure	RDS-EVENT-0083	Aurora was unable to copy backup data from an Amazon S3 bucket. It is likely that the permissions for Aurora to access the Amazon S3 bucket are configured incorrectly. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 784) .
Failure	RDS-EVENT-0143	Scaling failed for the Aurora Serverless DB cluster.
Global failover	RDS-EVENT-0181	The failover of the global database has started. The process can be delayed because other operations are running on the DB cluster.
Global failover	RDS-EVENT-0182	The old primary instance in the global database isn't accepting writes. All volumes are synchronized.
Global failover	RDS-EVENT-0183	A replication lag is occurring during the synchronization phase of the global database failover.
Global failover	RDS-EVENT-0184	The volume topology of the global database is reestablished with the new primary volume.
Global failover	RDS-EVENT-0185	The global database failover is finished on the primary DB cluster. Replicas might take long to come online after the failover completes.
Global failover	RDS-EVENT-0186	The global database failover is canceled.
Global failover	RDS-EVENT-0187	The global failover to the DB cluster failed.
Maintenance	RDS-EVENT-0156	The DB cluster has a DB engine minor version upgrade available.
Notification	RDS-EVENT-0076	Migration to an Aurora DB cluster failed.
Notification	RDS-EVENT-0077	An attempt to convert a table from the source database to InnoDB failed during the migration to an Aurora DB cluster.
Notification	RDS-EVENT-0085	An error occurred while attempting to patch the Aurora DB cluster. Check your instance status, resolve the issue, and try again. For more information see Maintaining an Amazon Aurora DB cluster (p. 443) .
Notification	RDS-EVENT-0141	Scaling initiated for the Aurora Serverless DB cluster.
Notification	RDS-EVENT-0142	Scaling completed for the Aurora Serverless DB cluster.
Notification	RDS-EVENT-0144	Automatic pause initiated for the Aurora Serverless DB cluster.
Notification	RDS-EVENT-0145	The Aurora Serverless DB cluster paused.
Notification	RDS-EVENT-0146	Pause cancelled for the Aurora Serverless DB cluster.
Notification	RDS-EVENT-0147	Resume initiated for the Aurora Serverless DB cluster.

Category	RDS event ID	Description
Notification	RDS-EVENT-0148	Resume completed for the Aurora Serverless DB cluster.
Notification	RDS-EVENT-0149	Seamless scaling completed with the force option for the Aurora Serverless DB cluster. Connections might have been interrupted as required.
Notification	RDS-EVENT-0150	The DB cluster stopped.
Notification	RDS-EVENT-0151	The DB cluster started.
Notification	RDS-EVENT-0152	The DB cluster stop failed.
Notification	RDS-EVENT-0153	The DB cluster is being started due to it exceeding the maximum allowed time being stopped.
Notification	RDS-EVENT-0173	Patching of the DB cluster has completed.

DB cluster snapshot events

The following table shows the event category and a list of events when an Aurora DB cluster snapshot is the source type.

Category	RDS event ID	Description
Backup	RDS-EVENT-0074	Creation of a manual DB cluster snapshot has started.
Backup	RDS-EVENT-0075	A manual DB cluster snapshot has been created.
notification	RDS-EVENT-0162	DB cluster snapshot export task failed.
notification	RDS-EVENT-0163	DB cluster snapshot export task canceled.
notification	RDS-EVENT-0164	DB cluster snapshot export task completed.
backup	RDS-EVENT-0168	Creating automated cluster snapshot.
backup	RDS-EVENT-0169	Automated cluster snapshot created.
notification	RDS-EVENT-0172	Renamed DB cluster from [old DB cluster name] to [new DB cluster name].

RDS Proxy events

The following table shows the event category and a list of events when an RDS Proxy is the source type.

Category	RDS event ID	Description
Configuration change	RDS-EVENT-0204	RDS modified the DB proxy (RDS Proxy).
Configuration change	RDS-EVENT-0207	RDS modified the endpoint of the DB proxy (RDS Proxy).

Category	RDS event ID	Description
Configuration change	RDS-EVENT-0213	RDS detected the addition of the DB instance and automatically added it to the target group of the DB proxy (RDS Proxy).
Configuration change	RDS-EVENT-0214	RDS detected the deletion of the DB instance and automatically removed it from the target group of the DB proxy (RDS Proxy).
Configuration change	RDS-EVENT-XXXX	RDS detected the deletion of the DB cluster and automatically removed it from the target group of the DB proxy (RDS Proxy).
Creation	RDS-EVENT-0203	RDS created the DB proxy (RDS Proxy).
Creation	RDS-EVENT-0206	RDS created the endpoint for the DB proxy (RDS Proxy).
Deletion	RDS-EVENT-0205	RDS deleted the DB proxy (RDS Proxy).
Deletion	RDS-EVENT-0208	RDS deleted the endpoint of DB proxy (RDS Proxy).

Subscribing to Amazon RDS event notification

The simplest way to create a subscription is with the RDS console. If you choose to create event notification subscriptions using the CLI or API, you must create an Amazon Simple Notification Service topic and subscribe to that topic with the Amazon SNS console or Amazon SNS API. You will also need to retain the Amazon Resource Name (ARN) of the topic because it is used when submitting CLI commands or API operations. For information on creating an SNS topic and subscribing to it, see [Getting started with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide*.

You can specify the type of source you want to be notified of and the Amazon RDS source that triggers the event. These are defined by the **SourceType** (type of source) and the **SourcelIdentifier** (the Amazon RDS source generating the event). For example, **SourceType** might be `SourceType = db-instance`, whereas **SourcelIdentifier** might be `SourceIdentifier = myDBInstance1`. The following table shows possible combinations.

SourceType	SourcelIdentifier	Description
Specified	Specified	You receive notice of all DB instance events for the specified source.
Specified	Not specified	You receive notice of the events for that source type for all your Amazon RDS sources.
Not specified	Not specified	You receive notice of all events from all Amazon RDS sources belonging to your customer account.

Console

To subscribe to RDS event notification

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose **Create event subscription**.
4. In the **Create event subscription** dialog box, do the following:
 - a. For **Name**, enter a name for the event notification subscription.
 - b. For **Send notifications to**, choose an existing Amazon SNS ARN for an Amazon SNS topic, or choose **create topic** to enter the name of a topic and a list of recipients.
 - c. For **Source type**, choose a source type.
 - d. Choose **Yes** to enable the subscription. If you want to create the subscription but to not have notifications sent yet, choose **No**.
 - e. Depending on the source type you selected, choose the event categories and sources that you want to receive event notifications for.
 - f. Choose **Create**.

The Amazon RDS console indicates that the subscription is being created.

Name	Status	Source Type	Enabled
Configchangerdpgres	active	Instances	Yes
Test	creating	Instances	Yes

AWS CLI

To subscribe to RDS event notification, use the AWS CLI [create-event-subscription](#) command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

Example

For Linux, macOS, or Unix:

```
aws rds create-event-subscription \
--subscription-name myeventsubscription \
--sns-topic-arn arn:aws:sns:us-east-1:802#####:myawsuser-RDS \
--enabled
```

For Windows:

```
aws rds create-event-subscription ^
--subscription-name myeventsubscription ^
--sns-topic-arn arn:aws:sns:us-east-1:802#####:myawsuser-RDS ^
--enabled
```

API

To subscribe to Amazon RDS event notification, call the Amazon RDS API function [CreateEventSubscription](#). Include the following required parameters:

- `SubscriptionName`

- SnsTopicArn

Listings Amazon RDS event notification subscriptions

You can list your current Amazon RDS event notification subscriptions.

Console

To list your current Amazon RDS event notification subscriptions

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Event subscriptions**. The **Event subscriptions** pane shows all your event notification subscriptions.

Event subscriptions (2)		
	Name	Status
<input type="checkbox"/> Edit Delete Create event subscription		
<input type="checkbox"/>	Configchangerdpgres	 active
<input type="checkbox"/>	Postgresnotification	 active

AWS CLI

To list your current Amazon RDS event notification subscriptions, use the AWS CLI [describe-event-subscriptions](#) command.

Example

The following example describes all event subscriptions.

```
aws rds describe-event-subscriptions
```

The following example describes the *myfirsteventsubscription*.

```
aws rds describe-event-subscriptions --subscription-name myfirsteventsubscription
```

API

To list your current Amazon RDS event notification subscriptions, call the Amazon RDS API [DescribeEventSubscriptions](#) action.

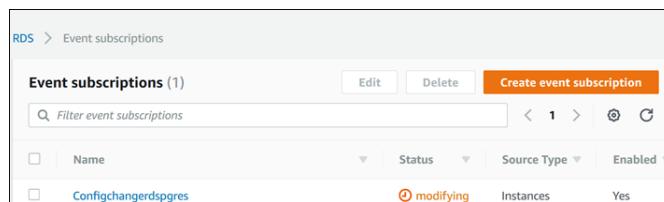

Modifying an Amazon RDS event notification subscription

After you have created a subscription, you can change the subscription name, source identifier, categories, or topic ARN.

Console

To modify an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose the subscription that you want to modify and choose **Edit**.
4. Make your changes to the subscription in either the **Target** or **Source** section.
5. Choose **Edit**. The Amazon RDS console indicates that the subscription is being modified.

AWS CLI

To modify an Amazon RDS event notification subscription, use the AWS CLI `modify-event-subscription` command. Include the following required parameter:

- `--subscription-name`

Example

The following code enables `myeventsSubscription`.

For Linux, macOS, or Unix:

```
aws rds modify-event-subscription \
--subscription-name myeventsSubscription \
--enabled
```

For Windows:

```
aws rds modify-event-subscription ^
--subscription-name myeventsSubscription ^
--enabled
```

API

To modify an Amazon RDS event, call the Amazon RDS API operation `ModifyEventSubscription`. Include the following required parameter:

- `SubscriptionName`

Adding a source identifier to an Amazon RDS event notification subscription

You can add a source identifier (the Amazon RDS source generating the event) to an existing subscription.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see [Modifying an Amazon RDS event notification subscription \(p. 687\)](#).

AWS CLI

To add a source identifier to an Amazon RDS event notification subscription, use the AWS CLI [add-source-identifier-to-subscription](#) command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example adds the source identifier `mysqldb` to the `myrdseventsSubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds add-source-identifier-to-subscription \
--subscription-name myrdseventsSubscription \
--source-identifier mysqldb
```

For Windows:

```
aws rds add-source-identifier-to-subscription ^
--subscription-name myrdseventsSubscription ^
--source-identifier mysqldb
```

API

To add a source identifier to an Amazon RDS event notification subscription, call the Amazon RDS API [AddSourceIdentifierToSubscription](#). Include the following required parameters:

- `SubscriptionName`
- `SourceIdentifier`

Removing a source identifier from an Amazon RDS event notification subscription

You can remove a source identifier (the Amazon RDS source generating the event) from a subscription if you no longer want to be notified of events for that source.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see [Modifying an Amazon RDS event notification subscription \(p. 687\)](#).

AWS CLI

To remove a source identifier from an Amazon RDS event notification subscription, use the AWS CLI `remove-source-identifier-from-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example removes the source identifier `mysqldb` from the `myrdseventsSubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds remove-source-identifier-from-subscription \
--subscription-name myrdseventsSubscription \
--source-identifier mysqldb
```

For Windows:

```
aws rds remove-source-identifier-from-subscription ^
--subscription-name myrdseventsSubscription ^
--source-identifier mysqldb
```

API

To remove a source identifier from an Amazon RDS event notification subscription, use the Amazon RDS API `RemoveSourceIdentifierFromSubscription` command. Include the following required parameters:

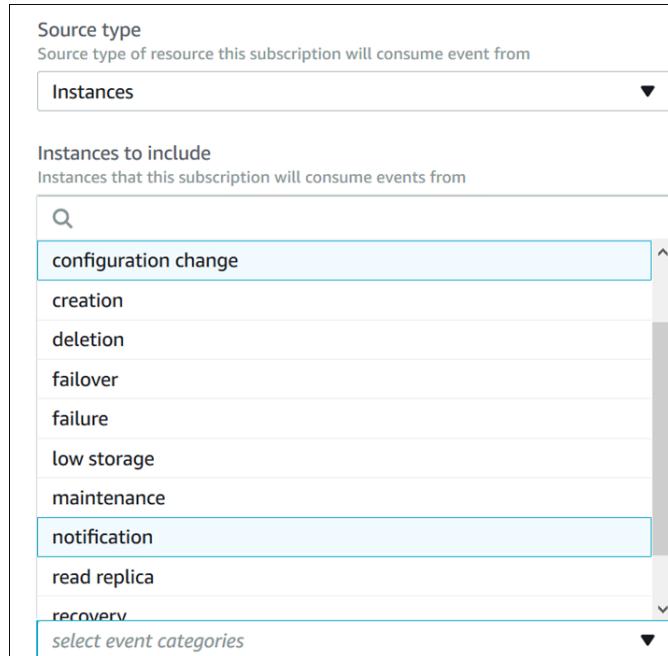

- `SubscriptionName`
- `SourceIdentifier`

Listing the Amazon RDS event notification categories

All events for a resource type are grouped into categories. To view the list of categories available, use the following procedures.

Console

When you create or modify an event notification subscription, the event categories are displayed in the Amazon RDS console. For more information, see [Modifying an Amazon RDS event notification subscription \(p. 687\)](#).

AWS CLI

To list the Amazon RDS event notification categories, use the AWS CLI [describe-event-categories](#) command. This command has no required parameters.

Example

```
aws rds describe-event-categories
```

API

To list the Amazon RDS event notification categories, use the Amazon RDS API [DescribeEventCategories](#) command. This command has no required parameters.

Deleting an Amazon RDS event notification subscription

You can delete a subscription when you no longer need it. All subscribers to the topic will no longer receive event notifications specified by the subscription.

Console

To delete an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **DB Event Subscriptions**.
3. In the **My DB Event Subscriptions** pane, choose the subscription that you want to delete.
4. Choose **Delete**.
5. The Amazon RDS console indicates that the subscription is being deleted.

The screenshot shows the 'Event subscriptions' section of the Amazon RDS console. It displays two entries in a table:

Name	Status
Configchangerdspgres	active
Postgresnotification	active

At the top of the table, there is a 'Delete' button which has been circled in red.

AWS CLI

To delete an Amazon RDS event notification subscription, use the AWS CLI `delete-event-subscription` command. Include the following required parameter:

- `--subscription-name`

Example

The following example deletes the subscription `myrdssubscription`.

```
aws rds delete-event-subscription --subscription-name myrdssubscription
```

API

To delete an Amazon RDS event notification subscription, use the RDS API `DeleteEventSubscription` command. Include the following required parameter:

- `SubscriptionName`

Creating a rule that triggers on an Amazon Aurora event

Using Amazon CloudWatch Events and Amazon EventBridge, you can automate AWS services and respond to system events such as application availability issues or resource changes.

Topics

- [Tutorial: log the state of an instance using EventBridge \(p. 692\)](#)

Tutorial: log the state of an instance using EventBridge

You can create an AWS Lambda function that logs the state changes for an instance. You can choose to create a rule that runs the function whenever there is a state transition or a transition to one or more states that are of interest.

In this tutorial, you log any state change of an existing RDS DB instance. The tutorial assumes that you have a small running test instance that you can shut down temporarily.

Important

Don't perform this tutorial on a running production instance.

Step 1: Create an AWS Lambda Function

Create a Lambda function to log the state change events. You specify this function when you create your rule.

To create a Lambda function

1. Open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. If you're new to Lambda, you see a welcome page. Choose **Get Started Now**. Otherwise, choose **Create function**.
3. Choose **Author from scratch**.
4. On the **Create function** page, do the following:
 - a. Enter a name and description for the Lambda function. For example, name the function **RDSInstanceStateChange**.
 - b. In **Runtime**, select **Node.js 14.x**.
 - c. In **Execution role**, choose **Create a new role with basic Lambda permissions**. For **Existing role**, select your basic execution role. Otherwise, create a basic execution role.
 - d. Choose **Create function**.
5. On the **RDSInstanceStateChange** page, do the following:
 - a. In **Code source**, select **index.js**.
 - b. Right-click **index.js**, and choose **Open**.
 - c. In the **index.js** pane, delete the existing code.
 - d. Enter the following code:

```
console.log('Loading function');

exports.handler = async (event, context) => {
    console.log('Received event:', JSON.stringify(event));
};
```
 - e. Choose **Deploy**.

Step 2: Create a Rule

Create a rule to run your Lambda function whenever you launch an Amazon RDS instance.

To create the EventBridge rule

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule. For example, enter **RDSInstanceStateChangeRule**.
5. For **Define pattern**, do the following:
 - a. Choose **Event pattern**.
 - b. Choose **Pre-defined pattern by service**.
 - c. For **Service provider**, choose **AWS**.
 - d. For **Service Name**, choose **Relational Database Service (RDS)**.
 - e. For **Event type**, choose **RDS DB Instance Event**.
6. For **Select event bus**, choose **AWS default event bus**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
7. For **Target**, choose **Lambda function**.
8. For **Function**, select the Lambda function that you created.
9. Choose **Create**.

Step 3: Test the Rule

To test your rule, shut down an RDS DB instance. After waiting a few minutes for the instance to shut down, verify that your Lambda function was invoked.

To test your rule by stopping a DB instance

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Stop an RDS DB instance.
3. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
4. In the navigation pane, choose **Rules**, choose the name of the rule that you created.
5. In **Rule details**, choose **Metrics for the rule**.

You are redirected to the Amazon CloudWatch console.
6. In **All metrics**, choose the name of the rule that you created.

The graph should indicate that the rule was invoked.
7. In the navigation pane, choose **Log groups**.
8. Choose the name of the log group for your Lambda function (`/aws/lambda/function-name`).
9. Choose the name of the log stream to view the data provided by the function for the instance that you launched. You should see a received event similar to the following:

```
{  
    "version": "0",  
    "id": "12a345b6-78c9-01d2-34e5-123f4ghi5j6k",  
    "detail-type": "RDS DB Instance Event",  
    "source": "aws.rds",  
    "account": "111111111111",  
    "time": "2021-03-19T19:34:09Z",  
    "region": "us-east-1",  
}
```

```
"resources": [
    "arn:aws:rds:us-east-1:111111111111:db:testdb"
],
"detail": {
    "EventCategories": [
        "notification"
    ],
    "SourceType": "DB_INSTANCE",
    "SourceArn": "arn:aws:rds:us-east-1:111111111111:db:testdb",
    "Date": "2021-03-19T19:34:09.293Z",
    "Message": "DB instance stopped",
    "SourceIdentifier": "testdb",
    "EventID": "RDS-EVENT-0087"
}
}
```

10. (Optional) When you're finished, you can open the Amazon RDS console and start the instance that you stopped.

Monitoring Amazon Aurora log files

You can view, download, and watch database logs using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. Viewing, downloading, or watching transaction logs isn't supported.

Note

In some cases, logs contain hidden data. Therefore, the AWS Management Console might show content in a log file, but the log file might be empty when you download it.

Topics

- [Viewing and listing database log files \(p. 695\)](#)
- [Downloading a database log file \(p. 696\)](#)
- [Watching a database log file \(p. 697\)](#)
- [Publishing database logs to Amazon CloudWatch Logs \(p. 697\)](#)
- [Reading log file contents using REST \(p. 698\)](#)
- [Aurora MySQL database log files \(p. 700\)](#)
- [PostgreSQL database log files \(p. 706\)](#)

Viewing and listing database log files

You can view database log files for your DB engine by using the AWS Management Console. You can list what log files are available for download or monitoring by using the AWS CLI or Amazon RDS API.

Console

To view a database log file

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, choose the log that you want to view, and then choose **View**.

AWS CLI

To list the available database log files for a DB instance, use the AWS CLI `describe-db-log-files` command.

The following example returns a list of log files for a DB instance named `my-db-instance`.

Example

```
aws rds describe-db-log-files --db-instance-identifier my-db-instance
```

RDS API

To list the available database log files for a DB instance, use the Amazon RDS API `DescribeDBLogFiles` action.

Downloading a database log file

You can use the AWS Management Console, AWS CLI or API to download a database log file.

Console

To download a database log file

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, choose the button next to the log that you want to download, and then choose **Download**.
7. Open the context (right-click) menu for the link provided, and then choose **Save Link As**. Enter the location where you want the log file to be saved, and then choose **Save**.

AWS CLI

To download a database log file, use the AWS CLI command `download-db-log-file-portion`. By default, this command downloads only the latest portion of a log file. However, you can download an entire file by specifying the parameter `--starting-token 0`.

The following example shows how to download the entire contents of a log file called `log/ERROR.4` and store it in a local file called `errorlog.txt`.

Example

For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \
    --db-instance-identifier myexampledb \
    --starting-token 0 --output text \
    --log-file-name log/ERROR.4 > errorlog.txt
```

For Windows:

```
aws rds download-db-log-file-portion ^
```

```
--db-instance-identifier myexampledb ^
--starting-token 0 --output text ^
--log-file-name log/ERROR.4 > errorlog.txt
```

RDS API

To download a database log file, use the Amazon RDS API [DownloadDBLogFilePortion](#) action.

Watching a database log file

You can monitor the contents of a log file by using the AWS Management Console.

Console

To watch a database log file

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. In the **Logs** section, choose a log file, and then choose **Watch**.

Publishing database logs to Amazon CloudWatch Logs

In addition to viewing and downloading DB instance logs, you can publish logs to Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, store the data in highly durable storage, and manage the data with the CloudWatch Logs Agent. AWS retains log data published to CloudWatch Logs for an indefinite time period unless you specify a retention period. For more information, see [Change log data retention in CloudWatch Logs](#).

Topics

- [Configuring CloudWatch log integration \(p. 697\)](#)
- [Engine-specific log information \(p. 698\)](#)

Configuring CloudWatch log integration

Before you enable log data publishing, make sure that you have a service-linked role in AWS Identity and Access Management (IAM). For more information about service-linked roles, see [Using service-linked roles for Amazon Aurora \(p. 1783\)](#).

To publish your database log files to CloudWatch Logs, choose which logs to publish. Make this choice in the **Advanced Settings** section when you create a new DB instance. You can also modify an existing DB instance to begin publishing.

Log exports

Select the log types to publish to Amazon CloudWatch Logs

- Audit log
- Error log
- General log
- Slow query log

IAM role

The following service-linked role is used for publishing logs to CloudWatch Logs.

RDS Service Linked Role

 Ensure that General, Slow Query, and Audit Logs are turned on. Error logs are enabled by default.

After you have enabled publishing, Amazon Aurora continuously streams all of the DB instance log records to a log group. For example, you have a log group `/aws/rds/cluster/<cluster_name>/log_type` for each type of log that you publish. This log group is in the same AWS Region as the database instance that generates the log.

After you have published log records, you can use CloudWatch Logs to search and filter the records. For more information about searching and filtering logs, see [Searching and filtering log data](#). For a tutorial explaining how to monitor RDS logs, see [Build proactive database monitoring for Amazon RDS with Amazon CloudWatch Logs, AWS Lambda, and Amazon SNS](#).

Engine-specific log information

For engine-specific information, see the following:

- [the section called “Publishing Aurora MySQL logs to CloudWatch Logs” \(p. 1017\)](#)
- [the section called “Publishing Aurora PostgreSQL logs to CloudWatch Logs” \(p. 1487\)](#)

Reading log file contents using REST

Amazon RDS provides a REST endpoint that allows access to DB instance log files. This is useful if you need to write an application to stream Amazon RDS log file contents.

The syntax is:

```
GET /v13/downloadCompleteLogFile/DBInstanceIdentifier/LogFileName HTTP/1.1
Content-type: application/json
host: rds.region.amazonaws.com
```

The following parameters are required:

- *DBInstanceIdentifier*—the name of the DB instance that contains the log file you want to download.
- *LogFileName*—the name of the log file to be downloaded.

The response contains the contents of the requested log file, as a stream.

The following example downloads the log file named *log/ERROR.6* for the DB instance named *sample-sql* in the *us-west-2* region.

```
GET /v13/downloadCompleteLogFile/sample-sql/log/ERROR.6 HTTP/1.1
host: rds.us-west-2.amazonaws.com
X-Amz-Security-Token: AQoDYXdzEIH//////////wEa0AIXLhngC5zp9CyB1R6abwKrXHVR5efnAVN3XvR7IwqKYalFSn6UyJuEFTft9nObglx4QJ+GXV9cpACkETq=
X-Amz-Date: 20140903T233749Z
X-Amz-Algorithm: AWS4-HMAC-SHA256
X-Amz-Credential: AKIADQKE4SARGYLE/20140903/us-west-2/rds/aws4_request
X-Amz-SignedHeaders: host
X-Amz-Content-SHA256: e3b0c44298fc1c229afbf4c8996fb92427ae41e4649b934de495991b7852b855
X-Amz-Expires: 86400
X-Amz-Signature: 353a4f14b3f250142d9afc34f9f9948154d46ce7d4ec091d0cdabbcf8b40c558
```

If you specify a nonexistent DB instance, the response consists of the following error:

- **DBInstanceNotFound**—*DB Instance Identifier* does not refer to an existing DB instance. (HTTP status code: 404)

Aurora MySQL database log files

You can monitor the Aurora MySQL logs directly through the Amazon RDS console, Amazon RDS API, AWS CLI, or AWS SDKs. You can also access MySQL logs by directing the logs to a database table in the main database and querying that table. You can use the `mysqlbinlog` utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see [Monitoring Amazon Aurora log files \(p. 695\)](#).

Topics

- [Overview of Aurora MySQL database logs \(p. 700\)](#)
- [Publishing Aurora MySQL logs to Amazon CloudWatch Logs \(p. 702\)](#)
- [Managing table-based Aurora MySQL logs \(p. 702\)](#)
- [Configuring Aurora MySQL binary logging \(p. 703\)](#)
- [Accessing MySQL binary logs \(p. 704\)](#)

Overview of Aurora MySQL database logs

You can monitor the following types of Aurora MySQL log files:

- Error log
- Slow query log
- General log
- The audit log

The Aurora MySQL error log is generated by default. You can generate the slow query and general logs by setting parameters in your DB parameter group.

Topics

- [Aurora MySQL error logs \(p. 700\)](#)
- [Aurora MySQL slow query and general logs \(p. 701\)](#)
- [Log rotation and retention \(p. 702\)](#)
- [Size limits on BLOBs \(p. 702\)](#)

Aurora MySQL error logs

Aurora MySQL writes errors in the `mysql-error.log` file. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

Aurora MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server did not encounter an error that would result in a log entry.

Aurora MySQL writes `mysql-error.log` to disk every 5 minutes. MySQL appends the contents of the log to `mysql-error-running.log`.

Aurora MySQL rotates the `mysql-error-running.log` file every hour. Aurora MySQL removes the audit, general, slow query, and SDK logs after either 24 hours or when 15% of storage has been consumed.

Note

The log retention period is different between Amazon RDS and Aurora.

Aurora MySQL slow query and general logs

The Aurora MySQL slow query log and the general log can be written to a file or a database table by setting parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs.

You can control Aurora MySQL logging by using the parameters in this list:

- `slow_query_log`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query run time to be logged, in seconds. The default is 10 seconds; the minimum is 0. If `log_output = FILE`, you can specify a floating point value that goes to microsecond resolution. If `log_output = TABLE`, you must specify an integer value with second resolution. Only queries whose run time exceeds the `long_query_time` value are logged. For example, setting `long_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set to 1. The default is 0. Queries that do not use an index are logged even if their run time is less than the value of the `long_query_time` parameter.
- `log_output option`: You can specify one of the following options for the `log_output` parameter.
 - **TABLE** – Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
 - **FILE** – Write both general and slow query logs to the file system. Log files are rotated hourly.
 - **NONE** – Disable logging.

For Aurora MySQL 5.6, the default for `log_output` is **TABLE**. For Aurora MySQL 5.7, the default for `log_output` is **FILE**.

When logging is enabled, Amazon Aurora rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. **FILE** and **TABLE** logging approach rotation and deletion as follows:

- When **FILE** logging is enabled, log files are examined every hour and log files more than 30 days old are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the oldest log files are deleted until the log file size no longer exceeds the threshold.
- When **TABLE** logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space or the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, then the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space or the size of all logs combined is greater than 5 GB. You can subscribe to the `low_free_storage` event to be notified when log tables are rotated to free up space. For more information, see [Using Amazon RDS event notification \(p. 675\)](#).

When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

You can rotate the `mysql.general_log` table by calling the `mysql.rds_rotate_general_log` procedure. You can rotate the `mysql.slow_log` table by calling the `mysql.rds_rotate_slow_log` procedure.

Table logs are rotated during a database version upgrade.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the `log_output` parameter to `FILE`. Like the MySQL error log, these log files are rotated hourly. The log files that were generated during the previous 30 days are retained. Note that the retention period is different between Amazon RDS and Aurora.

For more information about the slow query and general logs, go to the following topics in the MySQL documentation:

- [The slow query log](#)
- [The general query log](#)

Log rotation and retention

The Aurora MySQL slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour. Aurora MySQL removes logs after 24 hours or when 15% of disk space is reached. If the combined log file size exceeds the threshold after removing old log files, then the oldest log files are deleted until the log file size no longer exceeds the threshold.

Size limits on BLOBs

For Aurora MySQL, there is a size limit on BLOBs written to the redo log. To account for this limit, ensure that the `innodb_log_file_size` parameter for your Aurora MySQL DB instance is 10 times larger than the largest BLOB data size found in your tables, plus the length of other variable length fields (`VARCHAR`, `VARBINARY`, `TEXT`) in the same tables. For information on how to set parameter values, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#). For information on the redo log BLOB size limit, go to [Changes in MySQL 5.6.20](#).

Publishing Aurora MySQL logs to Amazon CloudWatch Logs

You can configure your Aurora MySQL DB cluster to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage. For more information, see [Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs \(p. 1017\)](#).

Managing table-based Aurora MySQL logs

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the `log_output` server parameter to `TABLE`. General queries are then logged to the `mysql.general_log` table, and slow queries are logged to the `mysql.slow_log` table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the `general_log` and `slow_query_log` server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to 0. A large amount of data often accumulates over time, which can use up a considerable

percentage of your allocated storage space. Amazon Aurora doesn't allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by **PROMPT>**:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

Configuring Aurora MySQL binary logging

The *binary log* is a set of log files that contain information about data modifications made to an Aurora MySQL server instance. The binary log contains information such as the following:

- Events that describe database changes such as table creation or row modifications
- Information about the duration of each statement that updated data
- Events for statements that could have updated data but didn't

The binary log records statements that are sent during replication. It is also required for some recovery operations. For more information, see [The Binary Log](#) and [Binary Log Overview](#) in the MySQL documentation.

MySQL on Amazon Aurora supports the *row-based*, *statement-based*, and *mixed* binary logging formats for MySQL version 5.6 and later. The default binary logging format is mixed. For details on the different Aurora MySQL binary log formats, see [Binary logging formats](#) in the MySQL documentation.

If you plan to use replication, the binary logging format is important because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see [Advantages and disadvantages of statement-based and row-based replication](#) in the MySQL documentation.

Important

Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB cluster and can increase the amount of time to perform a restore operation of a DB cluster.

Statement-based replication can cause inconsistencies between the source DB cluster and a read replica. For more information, see [Determination of safe and unsafe statements in binary logging](#) in the MySQL documentation.

To set the MySQL binary logging format

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group used by the DB cluster you want to modify.

You can't modify a default parameter group. If the DB cluster is using a default parameter group, create a new parameter group and associate it with the DB cluster.

For more information on parameter groups, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#).

4. From **Parameter group actions**, choose **Edit**.
5. Set the `binlog_format` parameter to the binary logging format of your choice (**ROW**, **STATEMENT**, or **MIXED**). You can also use the value **OFF** to turn off binary logging.
6. Choose **Save changes** to save the updates to the DB cluster parameter group.

Important

Changing a DB cluster parameter group affects all DB clusters that use that parameter group. If you want to specify different binary logging formats for different Aurora MySQL DB clusters in an AWS Region, the DB clusters must use different DB cluster parameter groups. These parameter groups identify different logging formats. Assign the appropriate DB cluster parameter group to each DB clusters. For more information about Aurora MySQL parameters, see [Aurora MySQL configuration parameters \(p. 1042\)](#).

Accessing MySQL binary logs

You can use the mysqlbinlog utility to download or stream binary logs from Amazon RDS instances running MySQL 5.6 or later. The binary log is downloaded to your local computer, where you can perform actions such as replaying the log using the mysql utility. For more information about using the mysqlbinlog utility, go to [Using mysqlbinlog to back up binary log files](#).

To run the mysqlbinlog utility against an Amazon RDS instance, use the following options:

- Specify the `--read-from-remote-server` option.
- `--host`: Specify the DNS name from the endpoint of the instance.
- `--port`: Specify the port used by the instance.
- `--user`: Specify a MySQL user that has been granted the replication slave permission.
- `--password`: Specify the password for the user, or omit a password value so that the utility prompts you for a password.
- To have the file downloaded in binary format, specify the `--raw` option.
- `--result-file`: Specify the local file to receive the raw output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command SHOW BINARY LOGS.
- To stream the binary log files, specify the `--stop-never` option.

For more information about mysqlbinlog options, go to [mysqlbinlog - utility for processing binary log files](#).

For example, see the following.

For Linux, macOS, or Unix:

```
mysqlbinlog \
  --read-from-remote-server \
  --host=MySQL56Instance1.cg034hpkmmt.region.rds.amazonaws.com \
  --port=3306 \
  --user ReplUser \
  --password \
  --raw \
  --result-file=/tmp/ \
  binlog.00098
```

For Windows:

```
mysqlbinlog ^
  --read-from-remote-server ^
  --host=MySQL56Instance1.cg034hpkmmt.region.rds.amazonaws.com ^
  --port=3306 ^
  --user ReplUser ^
  --password ^
  --raw ^
  --result-file=/tmp/ ^
```

```
binlog.00098
```

Amazon RDS normally purges a binary log as soon as possible, but the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

Note

The `mysql.rds_set_configuration` stored procedure is only available for MySQL version 5.6 or later.

The following example sets the retention period to 1 day.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` stored procedure.

```
call mysql.rds_show_configuration;
```

PostgreSQL database log files

Aurora PostgreSQL generates query and error logs. You can use log messages to troubleshoot performance and auditing issues while using the database.

To view, download, and watch file-based database logs, see [Monitoring Amazon Aurora log files \(p. 695\)](#).

Topics

- [Overview of PostgreSQL logs \(p. 706\)](#)
- [Setting the log retention period \(p. 707\)](#)
- [Setting log file rotation \(p. 707\)](#)
- [Setting the message format \(p. 708\)](#)
- [Enabling query logging \(p. 708\)](#)

Overview of PostgreSQL logs

PostgreSQL generates event log files that contain useful information for DBAs.

Log contents

The default logging level captures errors that affect your server. By default, Aurora PostgreSQL logging parameters capture all server errors, including the following:

- Query failures
- Login failures
- Fatal server errors
- Deadlocks

To identify application issues, you can use the preceding error messages. For example, if you converted a legacy application from Oracle to Aurora PostgreSQL, some queries may not convert correctly. These incorrectly formatted queries generate error messages in the logs, which you can use to identify the problematic code.

You can modify PostgreSQL logging parameters to capture additional information, including the following:

- Connections and disconnections
- Checkpoints
- Schema modification queries
- Queries waiting for locks
- Queries consuming temporary disk storage
- Backend autovacuum process consuming resources

The preceding log information can help troubleshoot potential performance and auditing issues. For more information, see [Error reporting and logging](#) in the PostgreSQL documentation. For a useful AWS blog about PostgreSQL logging, see [Working with RDS and Aurora PostgreSQL logs: Part 1](#) and [Working with RDS and Aurora PostgreSQL logs: Part 2](#).

Parameter groups

Each Aurora PostgreSQL instance is associated with a *parameter group* that contains the engine specific configurations. The engine configurations also include several parameters that control PostgreSQL

logging behavior. AWS provides the parameter groups with default configuration settings to use for your instances. However, to change the default settings, you must create a clone of the default parameter group, modify it, and attach it to your instance.

To set logging parameters for a DB instance, set the parameters in a DB parameter group and associate that parameter group with the DB instance. For more information, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#).

Setting the log retention period

To set the retention period for system logs, use the `rds.log_retention_period` parameter. You can find `rds.log_retention_period` in the DB parameter group associated with your DB instance. The unit for this parameter is minutes. For example, a setting of 1,440 retains logs for one day. The default value is 4,320 (three days). The maximum value is 10,080 (seven days). Your instance must have enough allocated storage to contain the retained log files.

Amazon Aurora compresses older PostgreSQL logs when storage for the DB instance reaches a threshold. Aurora compresses the files using the gzip compression utility; for information on gzip, see the [gzip](#) website. When storage for the DB instance is low and all available logs are compressed, you get a warning like the following.

Warning: local storage for PostgreSQL log files is critically low for this Aurora PostgreSQL instance, and could lead to a database outage.

Note

If storage gets too low, Aurora might delete compressed PostgreSQL logs before the retention period expires. If logs are deleted early, you get a message like the following.

The oldest PostgreSQL log files were deleted due to local storage constraints.

To retain older logs, publish them to Amazon CloudWatch Logs. For more information, see [Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs \(p. 1487\)](#). After you set up CloudWatch publishing, Aurora doesn't delete a log until it's published to CloudWatch Logs.

Setting log file rotation

To control PostgreSQL log file rotation, set two parameters in the DB parameter group associated with your DB instance: `log_rotation_age` and `log_rotation_size`. These two settings control when a new, distinct log file is created.

The log file names are based on the file name pattern of the `log_filename` parameter. For example, to provide log files names with a granularity of less than an hour, set `log_filename` to the minute format: `postgresql.log.%Y-%m-%d-%H%M`. Granularity of less than an hour is only supported for PostgreSQL version 10 and higher. To use a granularity in hours for log file names, set `log_filename` to the hour format: `postgresql.log.%Y-%m-%d-%H`.

To control log file rotation based on time, set the `log_rotation_age` parameter to anywhere from 1 minute to 1,440 minutes (24 hours). The `log_rotation_age` default is 60 minutes. If you set the `log_rotation_age` parameter to less than 60 minutes, also set the `log_filename` parameter to the minute format.

To control log file rotation based on file size, set the `log_rotation_size` parameter to anywhere from 50,000 to 1,000,000 KB. The default is 100,000 KB. We recommend that you also set the `log_filename` parameter to the minute format. Doing this makes sure that you can create a new log file in less than an hour if the `log_rotation_age` parameter is 60 minutes or greater.

Setting the message format

By default, Aurora PostgreSQL generates logs in standard error (stderr) format. In this format, each log message is prefixed with the information specified by the parameter `log_line_prefix`. Aurora only allows the following value for `log_line_prefix`:

```
%t:%r:%u@%d:[%p]:t
```

The preceding value maps to the following code:

```
log-time : remote-host : user-name @ db-name : [ process-id ]
```

For example, the following error message results from querying a column using the wrong name.

```
2019-03-10 03:54:59 UTC:10.0.0.123(52834):postgres@tstldb:[20175]:ERROR: column "wrong" does not exist at character 8
```

To specify the format for output logs, use the parameter `log_destination`. To make the instance generate both standard and CSV output files, set `log_destination` to `csvlog` in your instance parameter group. For a discussion of PostgreSQL logs, see [Working with RDS and Aurora PostgreSQL logs: Part 1](#).

Enabling query logging

To enable query logging for your PostgreSQL DB instance, set two parameters in the DB parameter group associated with your DB instance: `log_statement` and `log_min_duration_statement`.

The `log_statement` parameter controls which SQL statements are logged. The default value is `none`. We recommend that when you debug issues in your DB instance, set this parameter to `all` to log all statements. To log all data definition language (DDL) statements (`CREATE`, `ALTER`, `DROP`, and so on), set this value to `dd1`. To log all DDL and data modification language (DML) statements (`INSERT`, `UPDATE`, `DELETE`, and so on), set the value to `mod`.

Warning

Sensitive information such as passwords can be exposed if you set the `log_statement` parameter to `dd1`, `mod`, or `all`. To avoid this risk, set the `log_statement` to `none`. Also consider the following solutions:

- Encrypt the sensitive information on the client side and use the `ENCRYPTED` and `UNENCRYPTED` options of the `CREATE` and `ALTER` statements.
- Restrict access to the CloudWatch logs.
- Use stronger authentication mechanisms such as IAM.

For auditing, you can use the PostgreSQL `pgAudit` extension because it redacts the sensitive information for `CREATE` and `ALTER` commands.

The `log_min_duration_statement` parameter sets the limit in milliseconds of a statement to be logged. All SQL statements that run longer than the parameter setting are logged. This parameter is disabled and set to `-1` by default. Enabling this parameter can help you find unoptimized queries.

To set up query logging, take the following steps:

1. Set the `log_statement` parameter to `all`. The following example shows the information that is written to the `postgres.log` file.

```
2013-11-05 16:48:56 UTC::@[2952]:LOG: received SIGHUP, reloading configuration files
2013-11-05 16:48:56 UTC::@[2952]:LOG: parameter "log_statement" changed to "all"
```

Additional information is written to the `postgres.log` file when you run a query. The following example shows the type of information written to the file after a query.

```
2013-11-05 16:41:07 UTC::@[2955]:LOG: checkpoint starting: time
2013-11-05 16:41:07 UTC::@[2955]:LOG: checkpoint complete: wrote 1 buffers (0.3%),
0 transaction log file(s) added, 0 removed, 1 recycled; write=0.000 s, sync=0.003 s,
total=0.012 s; sync files=1, longest=0.003 s, average=0.003 s
2013-11-05 16:45:14 UTC:[local]:master@postgres:[8839]:LOG: statement: SELECT d.datname
as "Name",
    pg_catalog.pg_get_userbyid(d.datdba) as "Owner",
    pg_catalog.pg_encoding_to_char(d.encoding) as "Encoding",
    d.datcollate as "Collate",
    d.datctype as "Ctype",
    pg_catalog.array_to_string(d.datacl, E'\n') AS "Access privileges"
FROM pg_catalog.pg_database d
ORDER BY 1;
2013-11-05 16:45:
```

- Set the `log_min_duration_statement` parameter. The following example shows the information that is written to the `postgres.log` file when the parameter is set to 1.

```
2013-11-05 16:48:56 UTC::@[2952]:LOG: received SIGHUP, reloading configuration files
2013-11-05 16:48:56 UTC::@[2952]:LOG: parameter "log_min_duration_statement" changed to
"1"
```

Additional information is written to the `postgres.log` file when you run a query that exceeds the duration parameter setting. The following example shows the type of information written to the file after a query.

```
2013-11-05 16:51:10 UTC:[local]:master@postgres:[9193]:LOG: statement: SELECT

Monitoring Amazon Aurora API calls in AWS CloudTrail

AWS CloudTrail is an AWS service that helps you audit your AWS account. AWS CloudTrail is turned on for your AWS account when you create it. For more information about CloudTrail, see the [AWS CloudTrail User Guide](#).

Topics

- [CloudTrail integration with Amazon Aurora \(p. 710\)](#)
- [Amazon Aurora log file entries \(p. 710\)](#)

CloudTrail integration with Amazon Aurora

All Amazon Aurora actions are logged by CloudTrail. CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon Aurora.

CloudTrail events

CloudTrail captures API calls for Amazon Aurora as events. An *event* represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Events include calls from the Amazon RDS console and from code calls to the Amazon RDS API operations.

Amazon Aurora activity is recorded in a CloudTrail event in **Event history**. You can use the CloudTrail console to view the last 90 days of recorded API activity and events in an AWS Region. For more information, see [Viewing events with CloudTrail event history](#).

CloudTrail trails

For an ongoing record of events in your AWS account, including events for Amazon Aurora, create a *trail*. A trail is a configuration that enables delivery of events to a specified Amazon S3 bucket. CloudTrail typically delivers log files within 15 minutes of account activity.

Note

If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**.

You can create two types of trails for an AWS account: a trail that applies to all Regions, or a trail that applies to one Region. By default, when you create a trail in the console, the trail applies to all Regions.

Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- [Overview for creating a trail](#)
- [CloudTrail supported services and integrations](#)
- [Configuring Amazon SNS notifications for CloudTrail](#)
- [Receiving CloudTrail log files from multiple Regions](#) and [Receiving CloudTrail log files from multiple accounts](#)

Amazon Aurora log file entries

CloudTrail log files contain one or more log entries. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `CreateDBInstance` action.

```
{

"caCertificateIdentifier": "rds-ca-2015",
"dbiResourceId": "db-ETDZIIXHEWY5N7GXVC4SH7H5IA",
"dBSecurityGroups": [],
"pendingModifiedValues": {
    "masterUserPassword": "*****",
    "pendingCloudwatchLogsExports": {
        "logTypesToEnable": [
            "audit",
            "error",
            "general",
            "slowquery"
        ]
    }
},
"dBInstanceStatus": "creating",
"publiclyAccessible": true,
"domainMemberships": [],
"copyTagsToSnapshot": false,
"dBInstanceIdentifier": "test-instance",
"licenseModel": "general-public-license",
"iAMDatabaseAuthenticationEnabled": false,
"performanceInsightsEnabled": false,
"vpcSecurityGroups": [
{
    "status": "active",
    "vpcSecurityGroupId": "sg-f839b688"
}
]
},
"requestID": "daf2e3f5-96a3-4df7-a026-863f96db793e",
"eventID": "797163d3-5726-441d-80a7-6eeb7464acd4",

```

```
    "eventType": "AwsApiCall",
    "recipientAccountId": "123456789012"
}
```

As shown in the `userIdentity` element in the preceding example, every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information about the `userIdentity`, see the [CloudTrail userIdentity element](#). For more information about `CreateDBInstance` and other Amazon Aurora actions, see the [Amazon RDS API Reference](#).

Monitoring Amazon Aurora with Database Activity Streams

By using Database Activity Streams, you can monitor near-real-time streams of database activity.

Topics

- [Overview of Database Activity Streams \(p. 714\)](#)
- [Network prerequisites for Aurora MySQL database activity streams \(p. 717\)](#)
- [Starting a database activity stream \(p. 718\)](#)
- [Getting the status of a database activity stream \(p. 720\)](#)
- [Stopping a database activity stream \(p. 720\)](#)
- [Monitoring database activity streams \(p. 721\)](#)
- [Managing access to database activity streams \(p. 743\)](#)

Overview of Database Activity Streams

As an Amazon Aurora database administrator, you need to safeguard your database and meet compliance and regulatory requirements. One strategy is to integrate database activity streams with your monitoring tools. In this way, you monitor and set alarms for auditing activity in your Amazon Aurora cluster.

Security threats are both external and internal. To protect against internal threats, you can control administrator access to data streams by configuring the Database Activity Streams feature. DBAs don't have access to the collection, transmission, storage, and processing of the streams.

Topics

- [How database activity streams work \(p. 714\)](#)
- [Asynchronous and synchronous mode for database activity streams \(p. 715\)](#)
- [Requirements for database activity streams \(p. 716\)](#)
- [Supported Aurora engine versions for database activity streams \(p. 716\)](#)
- [Supported DB instance classes for database activity streams \(p. 716\)](#)
- [Supported AWS Regions for database activity streams \(p. 717\)](#)

How database activity streams work

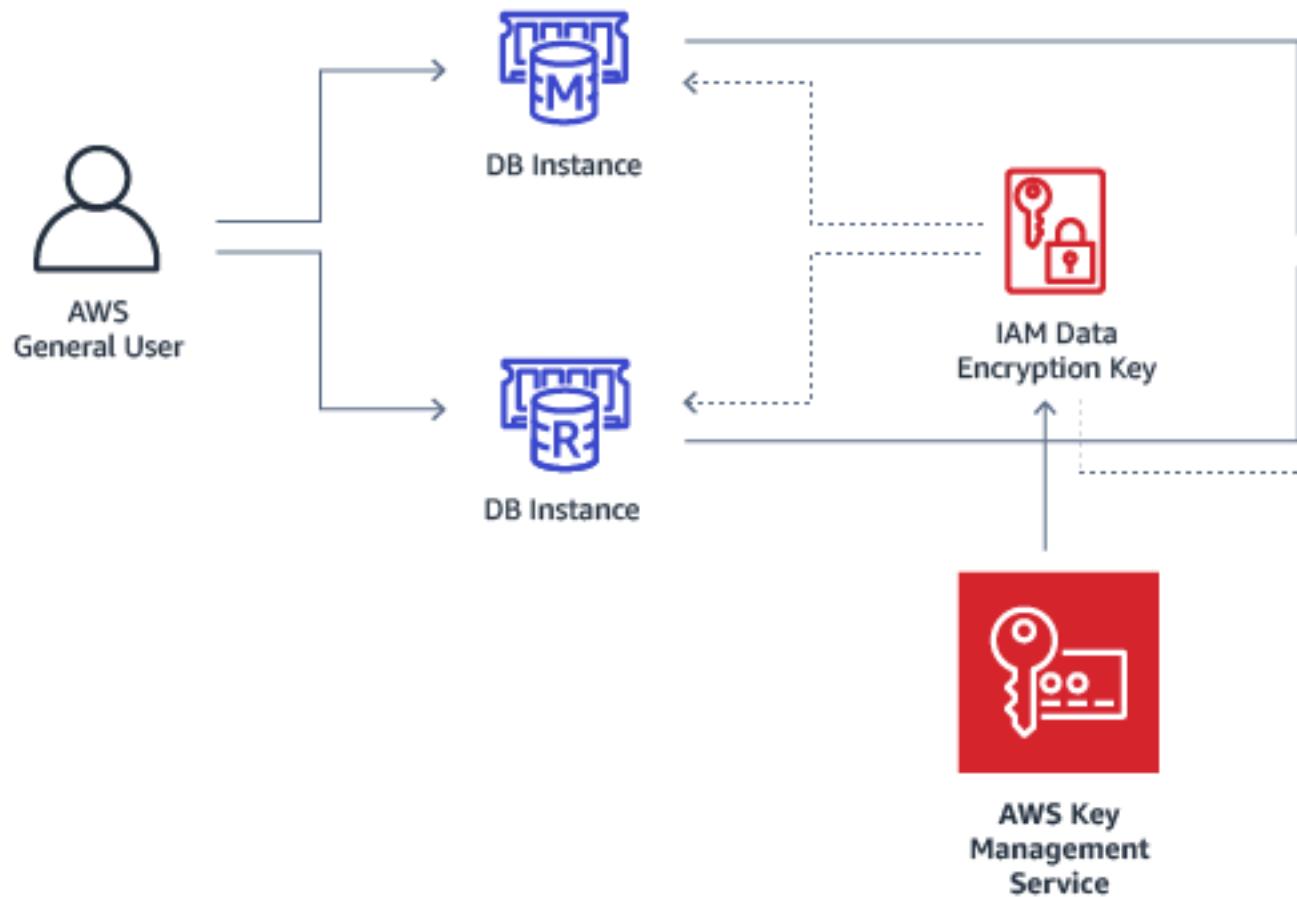

Amazon Aurora pushes activities to an Amazon Kinesis data stream in near real time. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Important

Use of the Database Activity Streams feature in Amazon Aurora and Amazon RDS is free, but Amazon Kinesis charges for a data stream. For more information, see [Amazon Kinesis Data Streams pricing](#).

Applications for compliance management can also consume database activity streams. For Aurora PostgreSQL, compliance applications include IBM's Security Guardium and Imperva's SecureSphere Database Audit and Protection. These applications can use the stream to generate alerts and audit activity on your Aurora DB cluster.

The following graphic shows an Aurora DB cluster configured with Amazon Kinesis Data Firehose.

Asynchronous and synchronous mode for database activity streams

You can choose to have the database session handle database activity events in either of the following modes:

- **Asynchronous mode** – When a database session generates an activity stream event, the session returns to normal activities immediately. In the background, the activity stream event is made a durable record. If an error occurs in the background task, an RDS event is sent. This event indicates the beginning and end of any time windows where activity stream event records might have been lost.

Asynchronous mode favors database performance over the accuracy of the activity stream.

Note

Asynchronous mode is available for both Aurora PostgreSQL and Aurora MySQL.

- **Synchronous mode** – When a database session generates an activity stream event, the session blocks other activities until the event is made durable. If the event can't be made durable for some reason, the database session returns to normal activities. However, an RDS event is sent indicating that activity stream records might be lost for some time. A second RDS event is sent after the system is back to a healthy state.

The synchronous mode favors the accuracy of the activity stream over database performance.

Note

Synchronous mode is available for Aurora PostgreSQL. You can't use synchronous mode with Aurora MySQL.

Requirements for database activity streams

In Aurora, database activity streams have the following requirements and limitations.

Topics

- [Miscellaneous requirements \(p. 716\)](#)

Miscellaneous requirements

- Database activity streams require use of AWS Key Management Service (AWS KMS). AWS KMS is required because the activity streams are always encrypted.
- Database activity streams require use of Amazon Kinesis.

Supported Aurora engine versions for database activity streams

For Aurora PostgreSQL, database activity streams are supported for the following versions:

- All 13 versions
- All 12 versions
- Version 11.6 and higher 11 versions
- Version 10.11 and higher 10 versions

For more information about Aurora PostgreSQL versions, see [Amazon Aurora PostgreSQL releases and engine versions \(p. 1599\)](#).

For Aurora MySQL, database activity streams are supported for version 2.08 or higher, which is compatible with MySQL version 5.7.

Note

Database activity streams aren't supported in Aurora Serverless.

Supported DB instance classes for database activity streams

For Aurora MySQL, you can use database activity streams with the following DB instance classes:

- db.r6g
- db.r5
- db.r4
- db.r3
- db.x2g

For Aurora PostgreSQL, you can use database activity streams with the following DB instance classes:

- db.r6g
- db.r5

- db.r4
- db.x2g

Supported AWS Regions for database activity streams

Database activity streams are supported in all AWS Regions except the following:

- China (Beijing) Region, `cn-north-1`
- China (Ningxia) Region, `cn-northwest-1`
- AWS GovCloud (US-East), `us-gov-east-1`
- AWS GovCloud (US-West), `us-gov-west-1`

Network prerequisites for Aurora MySQL database activity streams

In the following section, you can find how to configure your virtual private cloud (VPC) for use with database activity streams.

Topics

- [Prerequisites for AWS KMS endpoints \(p. 717\)](#)
- [Prerequisites for public availability \(p. 717\)](#)
- [Prerequisites for private availability \(p. 717\)](#)

Prerequisites for AWS KMS endpoints

Instances in an Aurora MySQL cluster that use activity streams must be able to access AWS KMS endpoints. Make sure this requirement is satisfied before enabling database activity streams for your Aurora MySQL cluster. If the Aurora cluster is publicly available, this requirement is satisfied automatically.

Important

If the Aurora MySQL DB cluster can't access the AWS KMS endpoint, the activity stream stops. In that case, Aurora notifies you about this issue using RDS Events.

Prerequisites for public availability

For an Aurora DB cluster to be public, it must meet the following requirements:

- **Publicly Accessible** is **Yes** in the AWS Management Console cluster details page.
- The DB cluster is in an Amazon VPC public subnet. For more information about publicly accessible DB instances, see [Working with a DB instance in a VPC \(p. 1787\)](#). For more information about public Amazon VPC subnets, see [Your VPC and Subnets](#).

Prerequisites for private availability

If your Aurora DB cluster isn't publicly accessible, and it's in a VPC public subnet, it's private. To keep your cluster private and use it with database activity streams, you have the following options:

- Configure Network Address Translation (NAT) in your VPC. For more information, see [NAT Gateways](#).

- Create an AWS KMS endpoint in your VPC. This option is recommended because it's easier to configure.

To create an AWS KMS endpoint in your VPC

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the navigation pane, choose **Endpoints**.
3. Choose **Create Endpoint**.
The **Create Endpoint** page appears.
4. Do the following:
 - In **Service category**, choose **AWS services**.
 - In **Service Name**, choose `com.amazonaws.region.kms`, where `region` is the AWS Region where your cluster is located.
 - For **VPC**, choose the VPC where your cluster is located.
5. Choose **Create Endpoint**.

For more information about configuring VPC endpoints, see [VPC Endpoints](#).

Starting a database activity stream

To monitor database activity for all instances of the DB cluster, start an activity stream at the cluster level. Any DB instances that you add to the cluster are also automatically monitored.

When you start an activity stream, each database activity event, such as a change or access, generates an activity stream event. SQL commands such as `CONNECT` and `SELECT` generate access events. SQL commands such as `CREATE` and `INSERT` generate change events.

Console

To start a database activity stream

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster for which you want to enable an activity stream.
4. For **Actions**, choose **Start activity stream**.

The **Start database activity stream: name** window appears, where `name` is your DB cluster.

5. Enter the following settings:

- For **AWS KMS key**, choose a key from the list of AWS KMS keys.

Note

If your Aurora MySQL cluster can't access KMS keys, follow the instructions in [Network prerequisites for Aurora MySQL database activity streams \(p. 717\)](#) to enable such access first.

Aurora uses the KMS key to encrypt the key that in turn encrypts database activity. Choose a KMS key other than the default key. For more information about encryption keys and AWS KMS, see [What is AWS Key Management Service?](#) in the *AWS Key Management Service Developer Guide*.

- For **Database activity stream mode**, choose **Asynchronous** or **Synchronous**.

Note

This choice applies only to Aurora PostgreSQL. For Aurora MySQL, you can use only asynchronous mode.

- Choose **Immediately**.

When you choose **Immediately**, the DB cluster restarts right away. If you choose **During the next maintenance window**, the DB cluster doesn't restart right away. In this case, the database activity stream doesn't start until the next maintenance window.

When you're done entering settings, choose **Start database activity stream**.

The status for the DB cluster shows that the activity stream is starting.

AWS CLI

To start database activity streams for a DB cluster , configure the DB cluster using the [start-activity-stream](#) AWS CLI command.

- `--kms-key-id key` – Specifies the KMS key identifier for encrypting messages in the database activity stream. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the AWS KMS key.
- `--resource-arn arn` – Specifies the Amazon Resource Name (ARN) of the DB cluster.
- `--region` – Identifies the AWS Region for the DB instance.
- `--mode sync-or-async` – Specifies either synchronous (`sync`) or asynchronous (`async`) mode. For Aurora PostgreSQL, you can choose either value. For Aurora MySQL, specify `async`.
- `--apply-immediately` – Applies the change immediately. This parameter is optional. If you don't specify this parameter, the database activity stream starts at the next maintenance interval.

For Linux, macOS, or Unix:

```
aws rds --region MY_REGION \
    start-activity-stream \
    --mode [sync | async] \
    --kms-key-id MY_KMS_KEY_ARN \
    --resource-arn MY_CLUSTER_ARN \
    --apply-immediately
```

For Windows:

```
aws rds --region MY_REGION ^
    start-activity-stream ^
    --mode [sync | async] ^
    --kms-key-id MY_KMS_KEY_ARN ^
    --resource-arn MY_CLUSTER_ARN ^
    --apply-immediately
```

RDS API

To start database activity streams for a DB cluster, configure the cluster using the [StartActivityStream](#) operation.

Call the action with the parameters below:

- Region
- Mode
- ApplyImmediately

Getting the status of a database activity stream

You can get the status of an activity stream using the console or AWS CLI.

Console

To get the status of a database activity stream

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB cluster link.
3. Choose the **Configuration** tab, and check **Database activity stream** for status.

AWS CLI

You can get the activity stream configuration for a DB cluster as the response to a [describe-db-clusters](#) CLI request. In the following example, see the values for `ActivityStreamKinesisStreamName`, `ActivityStreamStatus`, `ActivityStreamKmsKeyId`, and `ActivityStreamMode`.

The request is as follows.

```
aws rds --region MY_REGION describe-db-clusters --db-cluster-identifier my-cluster
```

The response includes the following items for a database activity stream.

The following example shows a JSON response. These fields are the same for Aurora PostgreSQL and Aurora MySQL, except that `ActivityStreamMode` is always `async` for Aurora MySQL, while for Aurora PostgreSQL it might be `sync` or `async`.

```
{  
    "DBClusters": [  
        {  
            "DBClusterIdentifier": "my-cluster",  
            ...  
            "ActivityStreamKinesisStreamName": "aws-rds-das-cluster-  
A6TSYXITZCZXJHIRVFUBZ5LTWY",  
            "ActivityStreamStatus": "starting",  
            "ActivityStreamKmsKeyId": "12345678-abcd-efgh-ijkl-bd041f170262",  
            "ActivityStreamMode": "async",  
            "DbClusterResourceId": "cluster-ABCD123456"  
            ...  
        }  
    ]  
}
```

RDS API

You can get the activity stream configuration for a DB cluster as the response to a [DescribeDBClusters](#) operation.

Stopping a database activity stream

You can stop an activity stream using the console or AWS CLI.

If you delete your DB cluster, the activity stream is stopped and the underlying Amazon Kinesis stream is deleted automatically.

Console

To turn off an activity stream

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose a DB cluster that you want to stop the database activity stream for.
4. For **Actions**, choose **Stop activity stream**. The **Database Activity Stream** window appears.
 - a. Choose **Immediately**.

When you choose **Immediately**, the DB cluster restarts right away. If you choose **During the next maintenance window**, the DB cluster doesn't restart right away. In this case, the database activity stream doesn't stop until the next maintenance window.

- b. Choose **Continue**.

AWS CLI

To stop database activity streams for your DB cluster, configure the DB cluster using the AWS CLI command `stop-activity-stream`. Identify the AWS Region for the DB cluster using the `--region` parameter. The `--apply-immediately` parameter is optional.

For Linux, macOS, or Unix:

```
aws rds --region MY_REGION \
  stop-activity-stream \
  --resource-arn MY_CLUSTER_ARN \
  --apply-immediately
```

For Windows:

```
aws rds --region MY_REGION ^
  stop-activity-stream ^
  --resource-arn MY_CLUSTER_ARN ^
  --apply-immediately
```

RDS API

To stop database activity streams for your DB cluster, configure the cluster using the `StopActivityStream` operation. Identify the AWS Region for the DB cluster using the `Region` parameter. The `ApplyImmediately` parameter is optional.

Monitoring database activity streams

Database activity streams monitor and report activities. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream, or other services and applications can consume the activity stream for further analysis. You can find the underlying Kinesis stream name by using the AWS CLI command `describe-db-clusters` or the RDS API `DescribeDBClusters` operation.

Aurora manages the Kinesis stream for you as follows:

- Aurora creates the Kinesis stream automatically with a 24-hour retention period.

- Aurora scales the Kinesis stream if necessary.
- If you stop the database activity stream or delete the DB cluster, Aurora deletes the Kinesis stream.

The following categories of activity are monitored and put in the activity stream audit log:

- **SQL commands** – All SQL commands are audited, and also prepared statements, built-in functions, and functions in PL/SQL. Calls to stored procedures are audited. Any SQL statements issued inside stored procedures or functions are also audited.
- **Other database information** – Activity monitored includes the full SQL statement, the row count of affected rows from DML commands, accessed objects, and the unique database name. For Aurora PostgreSQL, database activity streams also monitor the bind variables and stored procedure parameters.

Important

The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Aurora can determine them from the context, such as in the following SQL statement.

```
ALTER ROLE role-name WITH password
```

- **Connection information** – Activity monitored includes session and network information, the server process ID, and exit codes.

If an activity stream has a failure while monitoring your DB instance, you are notified through RDS events.

Topics

- [Accessing an activity stream from Kinesis \(p. 722\)](#)
- [Audit log contents and examples \(p. 723\)](#)
- [Processing a database activity stream using the AWS SDK \(p. 737\)](#)

Accessing an activity stream from Kinesis

When you enable an activity stream for a DB cluster, a Kinesis stream is created for you. From Kinesis, you can monitor your database activity in real time. To further analyze database activity, you can connect your Kinesis stream to consumer applications. You can also connect the stream to compliance management applications such as IBM's Security Guardium or Imperva's SecureSphere Database Audit and Protection.

To access an activity stream from Kinesis

1. Open the Kinesis console at <https://console.aws.amazon.com/kinesis>.
2. Choose your activity stream from the list of Kinesis streams.

An activity stream's name includes the prefix `aws-rds-das-cluster-` followed by the resource ID of the DB cluster. The following is an example.

```
aws-rds-das-cluster-NHVOV4PCLWHGF52NP
```

To use the Amazon RDS console to find the resource ID for the DB cluster, choose your DB cluster from the list of databases, and then choose the **Configuration** tab.

To use the AWS CLI to find the full Kinesis stream name for an activity stream, use a `describe-db-clusters` CLI request and note the value of `ActivityStreamKinesisStreamName` in the response.

3. Choose **Monitoring** to begin observing the database activity.

For more information about using Amazon Kinesis, see [What Is Amazon Kinesis Data Streams?](#).

Audit log contents and examples

Monitored events are represented in the database activity stream as JSON strings. The structure consists of a JSON object containing a `DatabaseActivityMonitoringRecord`, which in turn contains a `databaseActivityEventList` array of activity events.

            "netProtocol": "TCP",
            "dbProtocol": "Postgres 3.0",
            "type": "record",
            "errorMessage": null
        }
    ],
    "key": "decryption-key"
}
```

Example Activity event record of an Aurora MySQL CREATE TABLE statement

Following is an example of a `CREATE TABLE` statement for Aurora MySQL. The operation is represented as two separate event records. One event has `"class": "MAIN"`. The other event has `"class": "AUX"`. The messages might arrive in any order. The `logTime` field of the `MAIN` event is always earlier than the `logTime` fields of any corresponding `AUX` events.

The following example shows the event with a `class` value of `MAIN`.

```
{
    "type": "DatabaseActivityMonitoringRecord",
    "clusterId": "cluster-some_id",
    "instanceId": "db-some_id",
    "databaseActivityEventList": [
        {
            "logTime": "2020-05-22 18:07:12.250221+00",
            "type": "record",
            "clientApplication": null,
            "pid": 2830,
            "dbUserName": "master",
            "databaseName": "test",
            "remoteHost": "localhost",
            "remotePort": "11054",
            "command": "QUERY",
            "sqlText": "CREATE TABLE test_table (id INT PRIMARY KEY, name VARCHAR(255))"
        }
    ]
}
```

```

    "commandText":"CREATE TABLE test1 (id INT)",
    "paramList":null,
    "objectType":"TABLE",
    "objectName":"test1",
    "statementId":65459278,
    "substatementId":1,
    "exitCode":"0",
    "sessionId":"725118",
    "rowCount":0,
    "serverHost":"master",
    "serverType":"MySQL",
    "serviceName":"Amazon Aurora MySQL",
    "serverVersion":"MySQL 5.7.12",
    "startTime":"2020-05-22 18:07:12.226384+00",
    "endTime":"2020-05-22 18:07:12.250222+00",
    "transactionId":"0",
    "dbProtocol":"MySQL",
    "netProtocol":"TCP",
    "errorMessage":"",
    "class":"MAIN"
}
]
}

```

The following example shows the corresponding event with a `class` value of `AUX`.

```

{
  "type":"DatabaseActivityMonitoringRecord",
  "clusterId":"cluster-some_id",
  "instanceId":"db-some_id",
  "databaseActivityEventList":[
    {
      "logTime":"2020-05-22 18:07:12.247182+00",
      "type":"record",
      "clientApplication":null,
      "pid":2830,
      "dbUserName":"master",
      "databaseName":"test",
      "remoteHost":"localhost",
      "remotePort":"11054",
      "command":"CREATE",
      "commandText":"test1",
      "paramList":null,
      "objectType":"TABLE",
      "objectName":"test1",
      "statementId":65459278,
      "substatementId":2,
      "exitCode":"",
      "sessionId":"725118",
      "rowCount":0,
      "serverHost":"master",
      "serverType":"MySQL",
      "serviceName":"Amazon Aurora MySQL",
      "serverVersion":"MySQL 5.7.12",
      "startTime":"2020-05-22 18:07:12.226384+00",
      "endTime":"2020-05-22 18:07:12.247182+00",
      "transactionId":"0",
      "dbProtocol":"MySQL",
      "netProtocol":"TCP",
      "errorMessage":"",
      "class":"AUX"
    }
  ]
}

```

Example Activity event record of an Aurora PostgreSQL SELECT statement

Following is an example of a SELECT event.

```
{
  "type": "DatabaseActivityMonitoringRecords",
  "version": "1.1",
  "databaseActivityEvents":
  {
    "type": "DatabaseActivityMonitoringRecord",
    "clusterId": "cluster-4HNY5V4RRNPKKYB7ICFKE5JBQQ",
    "instanceId": "db-FZJTMYKCXQBUUZ6VLU7NW3ITCM",
    "databaseActivityEventList": [
      {
        "startTime": "2019-05-24 00:39:49.920564+00",
        "logTime": "2019-05-24 00:39:49.940668+00",
        "statementId": 6,
        "substatementId": 1,
        "objectType": "TABLE",
        "command": "SELECT",
        "objectName": "public.my_table",
        "databaseName": "postgres",
        "dbUserName": "rdsadmin",
        "remoteHost": "172.31.3.195",
        "remotePort": "34534",
        "sessionId": "5ce73c6f.7e64",
        "rowCount": 10,
        "commandText": "select * from my_table;",
        "paramList": [],
        "pid": 32356,
        "clientApplication": "psql",
        "exitCode": null,
        "class": "READ",
        "serverVersion": "2.3.1",
        "serverType": "PostgreSQL",
        "serviceName": "Amazon Aurora PostgreSQL-Compatible edition",
        "serverHost": "172.31.3.192",
        "netProtocol": "TCP",
        "dbProtocol": "Postgres 3.0",
        "type": "record",
        "errorMessage": null
      }
    ]
  },
  "key": "decryption-key"
}
```

Example Activity event record of an Aurora MySQL SELECT statement

Following is an example of a SELECT event.

The following example shows the event with a class value of MAIN.

```
{
  "type": "DatabaseActivityMonitoringRecord",
  "clusterId": "cluster-some_id",
  "instanceId": "db-some_id",
  "databaseActivityEventList": [
    {
      "logTime": "2020-05-22 18:29:57.986467+00",
      "type": "record",
      "clientApplication": null,
      "pid": 2830,
```

```

        "dbUserName": "master",
        "databaseName": "test",
        "remoteHost": "localhost",
        "remotePort": "11054",
        "command": "QUERY",
        "commandText": "SELECT * FROM test1 WHERE id < 28",
        "paramList": null,
        "objectType": "TABLE",
        "objectName": "test1",
        "statementId": 65469218,
        "substatementId": 1,
        "exitCode": "0",
        "sessionId": "726571",
        "rowCount": 2,
        "serverHost": "master",
        "serverType": "MySQL",
        "serviceName": "Amazon Aurora MySQL",
        "serverVersion": "MySQL 5.7.12",
        "startTime": "2020-05-22 18:29:57.986364+00",
        "endTime": "2020-05-22 18:29:57.986467+00",
        "transactionId": "0",
        "dbProtocol": "MySQL",
        "netProtocol": "TCP",
        "errorMessage": "",
        "class": "MAIN"
    }
]
}

```

The following example shows the corresponding event with a `class` value of `AUX`.

```
{
    "type": "DatabaseActivityMonitoringRecord",
    "instanceId": "db-some_id",
    "databaseActivityEventList": [
        {
            "logTime": "2020-05-22 18:29:57.986399+00",

            "objectName": "test1",
            "statementId": 65469218,
            "substatementId": 2,
            "exitCode": "",
            "sessionId": "726571",
            "rowCount": 0,
            "serverHost": "master",
            "serverType": "MySQL",
            "serviceName": "Amazon Aurora MySQL",
            "serverVersion": "MySQL 5.7.12",
            "startTime": "2020-05-22 18:29:57.986364+00",
            "endTime": "2020-05-22 18:29:57.986399+00",
            "transactionId": "0",
            "dbProtocol": "MySQL",
            "netProtocol": "TCP",
            "errorMessage": "",
            "class": "AUX"
        }
    ]
}
```

```
    ]
}
```

DatabaseActivityMonitoringRecords JSON object

The database activity event records are in a JSON object that contains the following information.

JSON Field	Data Type	Description
<code>type</code>	string	The type of JSON record. The value is <code>DatabaseActivityMonitoringRecords</code> .
<code>version</code>	string	<p>The version of the database activity monitoring records.</p> <p>The version of the generated database activity records depends on the engine version of the DB cluster:</p> <ul style="list-style-type: none"> Version 1.1 database activity records are generated for Aurora PostgreSQL DB clusters running the engine versions 10.10 and later minor versions and engine versions 11.5 and later. Version 1.0 database activity records are generated for Aurora PostgreSQL DB clusters running the engine versions 10.7 and 11.4. <p>All of the following fields are in both version 1.0 and version 1.1 except where specifically noted.</p>
<code>databaseActivityEvents</code> <small>(String)</small>	string	A JSON object containing the activity events.
<code>key</code>	string	An encryption key you use to decrypt the databaseActivityEventList (p. 730) <code>databaseActivityEventList</code> JSON array.

databaseActivityEvents JSON Object

The `databaseActivityEvents` JSON object contains the following information.

Top-level fields in JSON record

Each event in the audit log is wrapped inside a record in JSON format. This record contains the following fields.

`type`

This field always has the value `DatabaseActivityMonitoringRecords`.

`version`

This field represents the version of the database activity stream data protocol or contract. It defines which fields are available.

Version 1.0 represents the original data activity streams support for Aurora PostgreSQL versions 10.7 and 11.4. Version 1.1 represents the data activity streams support for Aurora PostgreSQL versions 10.10 and higher and Aurora PostgreSQL 11.5 and higher. Version 1.1 includes the additional fields `errorMessage` and `startTime`. Version 1.2 represents the data activity streams

support for Aurora MySQL 2.08 and higher. Version 1.2 includes the additional fields `endTime` and `transactionId`.

databaseActivityEvents

An encrypted string representing one or more activity events. It's represented as a base64 byte array. When you decrypt the string, the result is a record in JSON format with fields as shown in the examples in this section.

key

The encrypted data key used to encrypt the `databaseActivityEvents` string. This is the same AWS KMS key that you provided when you started the database activity stream.

The following example shows the format of this record.

```
{
  "type": "DatabaseActivityMonitoringRecords",
  "version": "1.1",
  "databaseActivityEvents": "encrypted audit records",
  "key": "encrypted key"
}
```

Take the following steps to decrypt the contents of the `databaseActivityEvents` field:

1. Decrypt the value in the `key` JSON field using the KMS key you provided when starting database activity stream. Doing so returns the data encryption key in clear text.
2. Base64-decode the value in the `databaseActivityEvents` JSON field to obtain the ciphertext, in binary format, of the audit payload.
3. Decrypt the binary ciphertext with the data encryption key that you decoded in the first step.
4. Decompress the decrypted payload.
 - The encrypted payload is in the `databaseActivityEvents` field.
 - The `databaseActivityEventList` field contains an array of audit records. The `type` fields in the array can be `record` or `heartbeat`.

The audit log activity event record is a JSON object that contains the following information.

JSON Field	Data Type	Description
<code>type</code>	string	The type of JSON record. The value is <code>DatabaseActivityMonitoringRecord</code> .
<code>clusterId</code>	string	The DB cluster resource identifier. It corresponds to the DB cluster attribute <code>DbClusterResourceId</code> .
<code>instanceId</code>	string	The DB instance resource identifier. It corresponds to the DB instance attribute <code>DbiResourceId</code> .
<code>databaseActivityEventList</code> <small>(String)</small>		An array of activity audit records or heartbeat messages.

databaseActivityEventList JSON array

The audit log payload is an encrypted `databaseActivityEventList` JSON array. The following tables lists alphabetically the fields for each activity event in the decrypted `DatabaseActivityEventList` array of an audit log. The fields differ depending on whether you use Aurora PostgreSQL or Aurora MySQL. Consult the table that applies to your database engine.

Important

The event structure is subject to change. Aurora might add new fields to activity events in the future. In applications that parse the JSON data, make sure that your code can ignore or take appropriate actions for unknown field names.

databaseActivityEventList fields for Aurora PostgreSQL

Field	Data Type	Description
class	string	<p>The class of activity event. Valid values for Aurora PostgreSQL are the following:</p> <ul style="list-style-type: none"> • ALL • CONNECT – A connect or disconnect event. • DDL – A DDL statement that is not included in the list of statements for the ROLE class. • FUNCTION – A function call or a DO block. • MISC – A miscellaneous command such as DISCARD, FETCH, CHECKPOINT, or VACUUM. • NONE • READ – A SELECT or COPY statement when the source is a relation or a query. • ROLE – A statement related to roles and privileges including GRANT, REVOKE, and CREATE/ALTER/DROP ROLE. • WRITE – An INSERT, UPDATE, DELETE, TRUNCATE, or COPY statement when the destination is a relation.
clientApplication	string	The application the client used to connect as reported by the client. The client doesn't have to provide this information, so the value can be null.
command	string	The name of the SQL command without any command details.
commandText	string	<p>The actual SQL statement passed in by the user. For Aurora PostgreSQL, the value is identical to the original SQL statement. This field is used for all types of records except for connect or disconnect records, in which case the value is null.</p> <p>Important The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Aurora can determine them from the context, such as in the following SQL statement.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <pre>ALTER ROLE role-name WITH password</pre> </div>
databaseName	string	The database to which the user connected.
dbProtocol	string	The database protocol, for example Postgres 3.0.
dbUserName	string	The database user with which the client authenticated.
errorMessage	string	If there was any error, this field is populated with the error message that would've been generated by the DB server. The errorMessage value is null for normal statements that didn't result in an error.

Field	Data Type	Description
(version 1.1 database activity records only)		<p>An error is defined as any activity that would produce a client-visible PostgreSQL error log event at a severity level of <code>ERROR</code> or greater. For more information, see PostgreSQL Message Severity Levels. For example, syntax errors and query cancellations generate an error message.</p> <p>Internal PostgreSQL server errors such as background checkpointer process errors do not generate an error message. However, records for such events are still emitted regardless of the setting of the log severity level. This prevents attackers from turning off logging to attempt avoiding detection.</p> <p>See also the <code>exitCode</code> field.</p>
<code>exitCode</code>	int	<p>A value used for a session exit record. On a clean exit, this contains the exit code. An exit code can't always be obtained in some failure scenarios. Examples are if PostgreSQL does an <code>exit()</code> or if an operator performs a command such as <code>kill -9</code>.</p> <p>If there was any error, the <code>exitCode</code> field shows the SQL error code, <code>SQLSTATE</code>, as listed in PostgreSQL Error Codes.</p> <p>See also the <code>errorMessage</code> field.</p>
<code>logTime</code>	string	A timestamp as recorded in the auditing code path. This represents the SQL statement execution end time. See also the <code>startTime</code> field.
<code>netProtocol</code>	string	The network communication protocol.
<code>objectName</code>	string	The name of the database object if the SQL statement is operating on one. This field is used only where the SQL statement operates on a database object. If the SQL statement is not operating on an object, this value is null.
<code>objectType</code>	string	<p>The database object type such as table, index, view, and so on. This field is used only where the SQL statement operates on a database object. If the SQL statement is not operating on an object, this value is null. Valid values include the following:</p> <ul style="list-style-type: none"> • <code>COMPOSITE TYPE</code> • <code>FOREIGN TABLE</code> • <code>FUNCTION</code> • <code>INDEX</code> • <code>MATERIALIZED VIEW</code> • <code>SEQUENCE</code> • <code>TABLE</code> • <code>TOAST TABLE</code> • <code>VIEW</code> • <code>UNKNOWN</code>
<code>paramList</code>	string	An array of comma-separated parameters passed to the SQL statement. If the SQL statement has no parameters, this value is an empty array.

Field	Data Type	Description
pid	int	The process ID of the backend process that is allocated for serving the client connection.
remoteHost	string	Either the client IP address or hostname. For Aurora PostgreSQL, which one is used depends on the database's <code>log_hostname</code> parameter setting.
remotePort	string	The client port number.
rowCount	int	The number of rows returned by the SQL statement. For example, if a SELECT statement returns 10 rows, rowCount is 10. For INSERT or UPDATE statements, rowCount is 0.
serverHost	string	The database server host IP address.
serverType	string	The database server type, for example <code>PostgreSQL</code> .
serverVersion	string	The database server version, for example <code>2.3.1</code> for Aurora PostgreSQL.
serviceName	string	The name of the service, for example <code>Amazon Aurora PostgreSQL-Compatible edition</code> .
sessionId	int	A pseudo-unique session identifier.
sessionID	int	A pseudo-unique session identifier.
startTime	string	The time when execution began for the SQL statement.
(version 1.1 database activity records only)		To calculate the approximate execution time of the SQL statement, use <code>logTime - startTime</code> . See also the <code>logTime</code> field.
statementId	int	An identifier for the client's SQL statement. The counter is at the session level and increments with each SQL statement entered by the client.
substatementId	int	An identifier for a SQL substatement. This value counts the contained substatements for each SQL statement identified by the <code>statementId</code> field.
type	string	The event type. Valid values are <code>record</code> or <code>heartbeat</code> .

databaseActivityEventList fields for Aurora MySQL

Field	Data Type	Description
class	string	<p>The class of activity event.</p> <p>Valid values for Aurora MySQL are the following:</p> <ul style="list-style-type: none"> • <code>MAIN</code> – The primary event representing a SQL statement. • <code>AUX</code> – A supplemental event containing additional details. For example, a statement that renames an object might have an event with class <code>AUX</code> that reflects the new name.

Field	Data Type	Description
		To find MAIN and AUX events corresponding to the same statement, check for different events that have the same values for the <code>pid</code> field and for the <code>statementId</code> field.
<code>clientApplication</code>	string	The application the client used to connect as reported by the client. The client doesn't have to provide this information, so the value can be null.
<code>command</code>	string	<p>The general category of the SQL statement. The values for this field depend on the value of <code>class</code>.</p> <p>The values when <code>class</code> is <code>MAIN</code> include the following:</p> <ul style="list-style-type: none"> • <code>CONNECT</code> – When a client session is connected. • <code>QUERY</code> – A SQL statement. Accompanied by one or more events with a <code>class</code> value of <code>AUX</code>. • <code>DISCONNECT</code> – When a client session is disconnected. • <code>FAILED_CONNECT</code> – When a client attempts to connect but isn't able to. • <code>CHANGEUSER</code> – A state change that's part of the MySQL network protocol, not from a statement that you issue. <p>The values when <code>class</code> is <code>AUX</code> include the following:</p> <ul style="list-style-type: none"> • <code>READ</code> – A <code>SELECT</code> or <code>COPY</code> statement when the source is a relation or a query. • <code>WRITE</code> – An <code>INSERT</code>, <code>UPDATE</code>, <code>DELETE</code>, <code>TRUNCATE</code>, or <code>COPY</code> statement when the destination is a relation. • <code>DROP</code> – Deleting an object. • <code>CREATE</code> – Creating an object. • <code>RENAME</code> – Renaming an object. • <code>ALTER</code> – Changing the properties of an object.

Field	Data Type	Description
commandText	string	<p>For events with a <code>class</code> value of <code>MAIN</code>, this field represents the actual SQL statement passed in by the user. This field is used for all types of records except for connect or disconnect records, in which case the value is null.</p> <p>For events with a <code>class</code> value of <code>AUX</code>, this field contains supplemental information about the objects involved in the event.</p> <p>For Aurora MySQL, characters such as quotation marks are preceded by a backslash, representing an escape character.</p> <p>Important The full SQL text of each statement is visible in the audit log, including any sensitive data. However, database user passwords are redacted if Aurora can determine them from the context, such as in the following SQL statement.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <pre>mysql> SET PASSWORD = '<i>my-password</i>';</pre> </div>
databaseName	string	The database to which the user connected.
dbProtocol	string	The database protocol. Currently, this value is always <code>MySQL</code> for Aurora MySQL.
dbUserName	string	The database user with which the client authenticated.
endTime (version 1.2 database activity records only)	string	<p>The time when execution ended for the SQL statement. It is represented in Coordinated Universal Time (UTC) format.</p> <p>To calculate the execution time of the SQL statement, use <code>endTime - startTime</code>. See also the <code>startTime</code> field.</p>
errorMessage (version 1.1 database activity records only)	string	<p>If there was any error, this field is populated with the error message that would've been generated by the DB server. The <code>errorMessage</code> value is null for normal statements that didn't result in an error.</p> <p>An error is defined as any activity that would produce a client-visible MySQL error log event at a severity level of <code>ERROR</code> or greater. For more information, see The Error Log in the <i>MySQL Reference Manual</i>. For example, syntax errors and query cancellations generate an error message.</p> <p>Internal MySQL server errors such as background checkpoint process errors do not generate an error message. However, records for such events are still emitted regardless of the setting of the log severity level. This prevents attackers from turning off logging to attempt avoiding detection.</p> <p>See also the <code>exitCode</code> field.</p>

Field	Data Type	Description
exitCode	int	A value used for a session exit record. On a clean exit, this contains the exit code. An exit code can't always be obtained in some failure scenarios. In such cases, this value might be zero or might be blank.
logTime	string	A timestamp as recorded in the auditing code path. It is represented in Coordinated Universal Time (UTC) format. For the most accurate way to calculate statement duration, see the startTime and endTime fields.
netProtocol	string	The network communication protocol. Currently, this value is always TCP for Aurora MySQL.
objectName	string	The name of the database object if the SQL statement is operating on one. This field is used only where the SQL statement operates on a database object. If the SQL statement isn't operating on an object, this value is blank. To construct the fully qualified name of the object, combine databaseName and objectName. If the query involves multiple objects, this field can be a comma-separated list of names.
objectType	string	<p>The database object type such as table, index, and so on. This field is used only where the SQL statement operates on a database object. If the SQL statement is not operating on an object, this value is null.</p> <p>Valid values for Aurora MySQL include the following:</p> <ul style="list-style-type: none"> • INDEX • TABLE • UNKNOWN
paramList	string	This field isn't used for Aurora MySQL and is always null.
pid	int	The process ID of the backend process that is allocated for serving the client connection. When the database server is restarted, the pid changes and the counter for the statementId field starts over.
remoteHost	string	Either the IP address or hostname of the client that issued the SQL statement. For Aurora MySQL, which one is used depends on the database's skip_name_resolve parameter setting. The value localhost indicates activity from the rdsadmin special user.
remotePort	string	The client port number.
rowCount	int	The number of table rows affected or retrieved by the SQL statement. This field is used only for SQL statements that are data manipulation language (DML) statements. If the SQL statement is not a DML statement, this value is null.
serverHost	string	The database server instance identifier. This value is represented differently for Aurora MySQL than for Aurora PostgreSQL. Aurora PostgreSQL uses an IP address instead of an identifier.
serverType	string	The database server type, for example MySQL.

Field	Data Type	Description
serverVersion	string	The database server version. Currently, this value is always MySQL 5.7.12 for Aurora MySQL.
serviceName	string	The name of the service. Currently, this value is always Amazon Aurora MySQL for Aurora MySQL.
sessionId	int	A pseudo-unique session identifier.
startTime (version 1.1 database activity records only)	string	The time when execution began for the SQL statement. It is represented in Coordinated Universal Time (UTC) format. To calculate the execution time of the SQL statement, use endTime - startTime. See also the endTime field.
statementId	int	An identifier for the client's SQL statement. The counter increments with each SQL statement entered by the client. The counter is reset when the DB instance is restarted.
substatementId	int	An identifier for a SQL substatement. This value is 1 for events with class MAIN and 2 for events with class AUX. Use the statementId field to identify all the events generated by the same statement.
transactionId (version 1.2 database activity records only)	int	An identifier for a transaction.
type	string	The event type. Valid values are record or heartbeat.

Processing a database activity stream using the AWS SDK

You can programmatically process an activity stream by using the AWS SDK. The following are fully functioning Java and Python examples of how you might process the Kinesis data stream.

Java

```

import java.io.ByteArrayInputStream;
import java.io.ByteArrayOutputStream;
import java.io.IOException;
import java.net.InetAddress;
import java.nio.ByteBuffer;
import java.nio.charset.StandardCharsets;

Managing access to database activity streams

Any user with appropriate AWS Identity and Access Management (IAM) role privileges for database activity streams can create, start, stop, and modify the activity stream settings for a DB cluster. These actions are included in the audit log of the stream. For best compliance practices, we recommend that you don't provide these privileges to DBAs.

You set access to database activity streams using IAM policies. For more information about Aurora authentication, see [Identity and access management in Amazon Aurora \(p. 1724\)](#). For more information about creating IAM policies, see [Creating and using an IAM policy for IAM database access \(p. 1746\)](#).

Example Policy to allow configuring database activity streams

To give users fine-grained access to modify activity streams, use the service-specific operation context keys `rds:StartActivityStream` and `rds:StopActivityStream` in an IAM policy. The following IAM policy example allows a user or role to configure activity streams.

```
{
    "Version": "2012-10-17",
    "Statement": [

```

```
{  
    "Sid": "ConfigureActivityStreams",  
    "Effect": "Allow",  
    "Action": [  
        "rds:StartActivityStream",  
        "rds:StopActivityStream"  
    ],  
    "Resource": "*",  
}  
}  
]
```

Example Policy to allow starting database activity streams

The following IAM policy example allows a user or role to start activity streams.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowStartActivityStreams",  
            "Effect": "Allow",  
            "Action": "rds:StartActivityStream",  
            "Resource": "*"  
        }  
    ]  
}
```

Example Policy to allow stopping database activity streams

The following IAM policy example allows a user or role to stop activity streams.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowStopActivityStreams",  
            "Effect": "Allow",  
            "Action": "rds:StopActivityStream",  
            "Resource": "*"  
        }  
    ]  
}
```

Example Policy to deny starting database activity streams

The following IAM policy example prevents a user or role from starting activity streams.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DenyStartActivityStreams",  
            "Effect": "Deny",  
            "Action": "rds:StartActivityStream",  
            "Resource": "*"  
        }  
    ]  
}
```

Example Policy to deny stopping database activity streams

The following IAM policy example prevents a user or role from stopping activity streams.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DenyStopActivityStreams",  
            "Effect": "Deny",  
            "Action": "rds:StopActivityStream",  
            "Resource": "*"  
        }  
    ]  
}
```

Working with Amazon Aurora MySQL

Amazon Aurora MySQL is a fully managed, MySQL-compatible, relational database engine that combines the speed and reliability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases. Aurora MySQL is a drop-in replacement for MySQL and makes it simple and cost-effective to set up, operate, and scale your new and existing MySQL deployments, thus freeing you to focus on your business and applications. Amazon RDS provides administration for Aurora by handling routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair. Amazon RDS also provides push-button migration tools to convert your existing Amazon RDS for MySQL applications to Aurora MySQL.

Amazon Aurora MySQL performance enhancements

Amazon Aurora includes performance enhancements to support the diverse needs of high-end commercial databases.

Fast insert

Fast insert accelerates parallel inserts sorted by primary key and applies specifically to `LOAD DATA` and `INSERT INTO ... SELECT ...` statements. Fast insert caches the position of a cursor in an index traversal while executing the statement. This avoids unnecessarily traversing the index again.

You can monitor the following metrics to determine the effectiveness of fast insert for your DB cluster:

- `aurora_fast_insert_cache_hits`: A counter that is incremented when the cached cursor is successfully retrieved and verified.
- `aurora_fast_insert_cache_misses`: A counter that is incremented when the cached cursor is no longer valid and Aurora performs a normal index traversal.

You can retrieve the current value of the fast insert metrics using the following command:

```
mysql> show global status like 'Aurora_fast_insert%';
```

You will get output similar to the following:

Variable_name	Value
Aurora_fast_insert_cache_hits	3598300
Aurora_fast_insert_cache_misses	436401336

Amazon Aurora MySQL and spatial data

The following list summarizes the main Aurora MySQL spatial features and explains how they correspond to spatial features in MySQL:

- Aurora MySQL 1.x supports the same spatial data types and spatial relation functions as MySQL 5.6. For more information about these data types and functions, see [Spatial Data Types](#) and [Spatial Relation Functions](#) in the MySQL 5.6 documentation.
- Aurora MySQL 2.x supports the same spatial data types and spatial relation functions as MySQL 5.7. For more information about these data types and functions, see [Spatial Data Types](#) and [Spatial Relation Functions](#) in the MySQL 5.7 documentation.
- Aurora MySQL 3.x supports the same spatial data types and spatial relation functions as MySQL 8.0. For more information about these data types and functions, see [Spatial Data Types](#) and [Spatial Relation Functions](#) in the MySQL 8.0 documentation.
- Aurora MySQL supports spatial indexing on InnoDB tables. Spatial indexing improves query performance on large datasets for queries on spatial data. In MySQL, spatial indexing for InnoDB tables isn't available in MySQL 5.6, but is available in MySQL 5.7 and 8.0. Aurora MySQL uses a different spatial indexing strategy than MySQL for high performance with spatial queries. The Aurora spatial index implementation uses a space-filling curve on a B-tree, which is intended to provide higher performance for spatial range scans than an R-tree.

The following data definition language (DDL) statements are supported for creating indexes on columns that use spatial data types.

CREATE TABLE

You can use the `SPATIAL INDEX` keywords in a `CREATE TABLE` statement to add a spatial index to a column in a new table. Following is an example.

```
CREATE TABLE test (shape POLYGON NOT NULL, SPATIAL INDEX(shape));
```

ALTER TABLE

You can use the `SPATIAL INDEX` keywords in an `ALTER TABLE` statement to add a spatial index to a column in an existing table. Following is an example.

```
ALTER TABLE test ADD SPATIAL INDEX(shape);
```

CREATE INDEX

You can use the `SPATIAL` keyword in a `CREATE INDEX` statement to add a spatial index to a column in an existing table. Following is an example.

```
CREATE SPATIAL INDEX shape_index ON test (shape);
```

Aurora MySQL version 3 compatible with MySQL 8.0

You can use Aurora MySQL version 3 to get the latest MySQL-compatible features, performance enhancements, and bug fixes. Following, you can learn about Aurora MySQL version 3, with MySQL 8.0 compatibility. You can learn how to upgrade your clusters and applications to Aurora MySQL version 3.

Topics

- [Features from community MySQL 8.0 \(p. 748\)](#)
- [New parallel query optimizations \(p. 749\)](#)
- [Release notes for Aurora MySQL version 3 \(p. 749\)](#)
- [Comparison of Aurora MySQL version 2 and Aurora MySQL version 3 \(p. 749\)](#)
- [Comparison of Aurora MySQL version 3 and community MySQL 8.0 \(p. 756\)](#)
- [Upgrading to Aurora MySQL version 3 \(p. 760\)](#)

Features from community MySQL 8.0

The initial release of Aurora MySQL version 3 is compatible with community MySQL 8.0.23. MySQL 8.0 introduces several new features, including the following:

- JSON functions. For usage information, see [JSON Functions](#) in the *MySQL Reference Manual*.
- Window functions. For usage information, see [Window Functions](#) in the *MySQL Reference Manual*.
- Common table expressions (CTEs), using the `WITH` clause. For usage information, see [WITH \(Common Table Expressions\)](#) in the *MySQL Reference Manual*.
- Optimized `ADD COLUMN` and `RENAME COLUMN` clauses for the `ALTER TABLE` statement. These optimizations are called "instant DDL." Aurora MySQL version 3 is compatible with the community MySQL instant DDL feature. The former Aurora fast DDL feature isn't used. For usage information for instant DDL, see [Instant DDL \(Aurora MySQL version 3\) \(p. 832\)](#).
- Descending, functional, and invisible indexes. For usage information, see [Invisible Indexes, Descending Indexes](#), and [CREATE INDEX Statement](#) in the *MySQL Reference Manual*.

- Role-based privileges controlled through SQL statements. For more information on changes to the privilege model, see [Role-based privilege model \(p. 757\)](#).
- `NOWAIT` and `SKIP LOCKED` clauses with the `SELECT ... FOR SHARE` statement. These clauses avoid waiting for other transactions to release row locks. For usage information, see [Locking Reads](#) in the *MySQL Reference Manual*.
- Improvements to binary log (binlog) replication. For the Aurora MySQL details, see [Binary log replication \(p. 756\)](#). In particular, you can perform filtered replication. For usage information about filtered replication, see [How Servers Evaluate Replication Filtering Rules](#) in the *MySQL Reference Manual*.
- Hints. Some of the MySQL 8.0-compatible hints were already backported to Aurora MySQL version 2. For information about using hints with Aurora MySQL, see [Aurora MySQL hints \(p. 1074\)](#). For the full list of hints in community MySQL 8.0, see [Optimizer Hints](#) in the *MySQL Reference Manual*.

For the full list of features added to MySQL 8.0 community edition, see the blog post [The complete list of new features in MySQL 8.0](#).

Aurora MySQL version 3 also includes changes to keywords for inclusive language, backported from community MySQL 8.0.26. For details about those changes, see [Inclusive language changes for Aurora MySQL version 3 \(p. 751\)](#).

New parallel query optimizations

The Aurora parallel query optimization now applies to more SQL operations:

- Parallel query now applies to tables containing the data types `TEXT`, `BLOB`, `JSON`, `GEOMETRY`, and `VARCHAR` and `CHAR` longer than 768 bytes.
- Parallel query can optimize queries involving partitioned tables.
- Parallel query can optimize queries involving aggregate function calls in the select list and the `HAVING` clause.

For more information about these enhancements, see [Upgrading parallel query clusters to Aurora MySQL version 3 \(p. 893\)](#). For general information about Aurora parallel query, see [Working with parallel query for Amazon Aurora MySQL \(p. 881\)](#).

Release notes for Aurora MySQL version 3

For the release notes for all Aurora MySQL version 3 releases, see [Database engine updates for Amazon Aurora MySQL version 3 \(p. 1108\)](#).

Comparison of Aurora MySQL version 2 and Aurora MySQL version 3

Use the following to learn about changes to be aware of when you upgrade your Aurora MySQL version 2 cluster to version 3.

Topics

- [Feature differences between Aurora MySQL version 2 and 3 \(p. 750\)](#)
- [Instance class support \(p. 750\)](#)
- [Parameter changes for Aurora MySQL version 3 \(p. 751\)](#)
- [Status variables \(p. 751\)](#)
- [Inclusive language changes for Aurora MySQL version 3 \(p. 751\)](#)
- [AUTO_INCREMENT values \(p. 753\)](#)
- [Temporary tables on reader DB instances \(p. 754\)](#)

- [Storage engine for internal temporary tables \(p. 754\)](#)
- [Binary log replication \(p. 756\)](#)

Feature differences between Aurora MySQL version 2 and 3

The following Amazon Aurora MySQL features are supported in Aurora MySQL for MySQL 5.7, but these features aren't supported in Aurora MySQL for MySQL 8.0:

- Backtrack currently isn't available for Aurora MySQL version 3 clusters. We intend to make this feature available in a subsequent minor version.

If you have an Aurora MySQL version 2 cluster that uses backtrack, currently you can't use the snapshot restore method to upgrade to Aurora MySQL version 3. This limitation applies to all clusters that use backtrack clusters, regardless of whether the backtrack setting is turned on. For details about upgrade procedures, see [Upgrading to Aurora MySQL version 3 \(p. 760\)](#).

- You can't use Aurora MySQL version 3 for Aurora Serverless v1 clusters. Aurora MySQL version 3 works with Aurora Serverless v2, which is currently in preview.
- Lab mode doesn't apply to Aurora MySQL version 3. There aren't any lab mode features in Aurora MySQL version 3. Instant DDL supersedes the fast online DDL feature that was formerly available in lab mode. For an example, see [Instant DDL \(Aurora MySQL version 3\) \(p. 832\)](#).
- The query cache is removed from community MySQL 8.0 and also from Aurora MySQL version 3.
- Aurora MySQL version 3 is compatible with the community MySQL hash join feature. The Aurora-specific implementation of hash joins in Aurora MySQL version 2 isn't used. For information about using hash joins with Aurora parallel query, see [Turning on hash join for parallel query clusters \(p. 892\)](#) and [Aurora MySQL hints \(p. 1074\)](#). For general usage information about hash joins, see [Hash Join Optimization](#) in the *MySQL Reference Manual*.
- Currently, you can't restore a physical backup from the Percona XtraBackup tool to an Aurora MySQL version 3 cluster. We intend to support this feature in a subsequent minor version.
- The `mysql.lambda_async` stored procedure that was deprecated in Aurora MySQL version 2 is removed in version 3. For version 3, use the asynchronous function `lambda_async` instead.
- The default character set in Aurora MySQL version 3 is `utf8mb4`. In Aurora MySQL version 2, the default character set was `latin1`. For information about this character set, see [The utf8mb4 Character Set \(4-Byte UTF-8 Unicode Encoding\)](#) in the *MySQL Reference Manual*.
- The `innodb_flush_log_at_trx_commit` configuration parameter can't be modified. The default value of 1 always applies.

Some Aurora MySQL features are available for certain combinations of AWS Region and DB engine version. For details, see [Supported features in Amazon Aurora by AWS Region and Aurora DB engine \(p. 19\)](#).

Instance class support

Aurora MySQL version 3 supports a different set of instance classes than Aurora MySQL version 2 does:

- For larger instances, you can use the modern instance classes such as `db.r5`, `db.r6g`, and `db.x2g`.
- For smaller instances, you can use the modern instance classes such as `db.t3` and `db.t4g`.

The following instance classes from Aurora MySQL version 2 aren't available for Aurora MySQL version 3:

- `db.r4`
- `db.r3`
- `db.t3.small`
- `db.t2`

Check your administration scripts for any CLI statements that create Aurora MySQL DB instances and hardcode instance class names that aren't available for Aurora MySQL version 3. If necessary, modify the instance class names to ones that Aurora MySQL version 3 supports.

Tip

To check the instance classes that you can use for a specific combination of Aurora MySQL version and AWS Region, use the `describe-orderable-db-instance-options` AWS CLI command.

For full details about Aurora instance classes, see [Aurora DB instance classes \(p. 54\)](#).

Parameter changes for Aurora MySQL version 3

Aurora MySQL version 3 includes new cluster-level and instance-level configuration parameters. Aurora MySQL version 3 also removes some parameters that were present in Aurora MySQL version 2. Some parameter names are changed as a result of the initiative for inclusive language. For backward compatibility, you can still retrieve the parameter values using either the old names or the new names. However, you must use the new names to specify parameter values in a custom parameter group.

In Aurora MySQL version 3, the value of the `lower_case_table_names` parameter is set permanently at the time the cluster is created. If you use a nondefault value for this option, set up your Aurora MySQL version 3 custom parameter group before upgrading. Then specify the parameter group during the create cluster or snapshot restore operation.

For the full list of Aurora MySQL cluster parameters, see [Cluster-level parameters \(p. 1043\)](#). The table covers all the parameters from Aurora MySQL version 1, 2, and 3. The table includes notes showing which parameters are new in Aurora MySQL version 3 or were removed from Aurora MySQL version 3.

For the full list of Aurora MySQL instance parameters, see [Instance-level parameters \(p. 1049\)](#). The table covers all the parameters from Aurora MySQL version 1, 2, and 3. The table includes notes showing which parameters are new in Aurora MySQL version 3 and which parameters were removed from Aurora MySQL version 3. It also includes notes showing which parameters were modifiable in earlier versions but not Aurora MySQL version 3.

For information about parameter names that changed, see [Inclusive language changes for Aurora MySQL version 3 \(p. 751\)](#).

Status variables

For information about status variables that aren't applicable to Aurora MySQL, see [MySQL status variables that don't apply to Aurora MySQL \(p. 1062\)](#).

Inclusive language changes for Aurora MySQL version 3

Aurora MySQL version 3 is compatible with version 8.0.23 from the MySQL community edition. Aurora MySQL version 3 also includes changes from MySQL 8.0.26 related to keywords and system schemas for inclusive language. For example, the `SHOW REPLICA STATUS` command is now preferred instead of `SHOW SLAVE STATUS`.

The following Amazon CloudWatch metrics have new names in Aurora MySQL version 3.

In Aurora MySQL version 3, only the new metric names are available. Make sure to update any alarms or other automation that relies on metric names when you upgrade to Aurora MySQL version 3.

Old name	New name
<code>ForwardingMasterDMLLatency</code>	<code>ForwardingWriterDMLLatency</code>
<code>ForwardingMasterOpenSessions</code>	<code>ForwardingWriterOpenSessions</code>
<code>AuroraDMLRejectedMasterFull</code>	<code>AuroraDMLRejectedWriterFull</code>

Old name	New name
ForwardingMasterDMLThroughput	ForwardingWriterDMLThroughput

The following status variables have new names in Aurora MySQL version 3.

For compatibility, you can use either name in the initial Aurora MySQL version 3 release. The old status variable names are to be removed in a future release.

Name to be removed	New or preferred name
Aurora_fwd_master_dml_stmt	Aurora_fwd_writer_dml_stmt_duration
Aurora_fwd_master_dml_stmt	Aurora_fwd_writer_dml_stmt_count
Aurora_fwd_master_select_stmt	Aurora_fwd_writer_select_stmt_duration
Aurora_fwd_master_select_stmt	Aurora_fwd_writer_select_stmt_count
Aurora_fwd_master_errors_session_timeout	Aurora_writer_errors_session_timeout
Aurora_fwd_master_open_sessions	Aurora_fwd_writer_open_sessions
Aurora_fwd_master_errors_sessions_limit	Aurora_fwd_writer_errors_session_limit
Aurora_fwd_master_errors_rpc_timeout	Aurora_fwd_writer_errors_rpc_timeout

The following configuration parameters have new names in Aurora MySQL version 3.

For compatibility, you can check the parameter values in the `mysql` client by using either name in the initial Aurora MySQL version 3 release. You can only modify the values in a custom parameter group by using the new names. The old parameter names are to be removed in a future release.

Name to be removed	New or preferred name
aurora_fwd_master_idle_timeout	Aurora_fwd_writer_idle_timeout
aurora_fwd_master_max_connections	Aurora_fwd_writer_max_connections_pct
master_verify_checksum	source_verify_checksum
sync_master_info	sync_source_info
init_slave	init_replica
rpl_stop_slave_timeout	rpl_stop_replica_timeout
log_slow_slave_statements	log_slow_replica_statements
slave_max_allowed_packet	replica_max_allowed_packet
slave_compressed_protocol	replica_compressed_protocol
slave_exec_mode	replica_exec_mode
slave_type_conversions	replica_type_conversions
slave_sql_verify_checksum	replica_sql_verify_checksum

Name to be removed	New or preferred name
slave_parallel_type	replica_parallel_type
slave_preserve_commit_order	replica_preserve_commit_order
log_slave_updates	log_replica_updates
slave_allow_batching	replica_allow_batching
slave_load_tmpdir	replica_load_tmpdir
slave_net_timeout	replica_net_timeout
sql_slave_skip_counter	sql_replica_skip_counter
slave_skip_errors	replica_skip_errors
slave_checkpoint_period	replica_checkpoint_period
slave_checkpoint_group	replica_checkpoint_group
slave_transaction_retries	replica_transaction_retries
slave_parallel_workers	replica_parallel_workers
slave_pending_jobs_size_max	replica_pending_jobs_size_max
pseudo_slave_mode	pseudo_replica_mode

The following stored procedures have new names in Aurora MySQL version 3.

For compatibility, you can use either name in the initial Aurora MySQL version 3 release. The old procedure names are to be removed in a future release.

Name to be removed	New or preferred name
mysql.rds_set_master_auto_position	mysql.rds_set_source_auto_position
mysql.rds_set_external_master	mysql.rds_set_external_source
mysql.rds_set_external_master	mysql.rds_set_external_source_with_auto_position
mysql.rds_reset_external_master	mysql.rds_reset_external_source
mysql.rds_next_master_log	mysql.rds_next_source_log

AUTO_INCREMENT values

In Aurora MySQL version 3, Aurora preserves the AUTO_INCREMENT value for each table when it restarts each DB instance. In Aurora MySQL version 2, the AUTO_INCREMENT value wasn't preserved after a restart.

The AUTO_INCREMENT value isn't preserved when you set up a new cluster by restoring from a snapshot, performing a point-in-time recovery, and cloning a cluster. In these cases, the AUTO_INCREMENT value is initialized to the value based on the largest column value in the table at the time the snapshot was created. This behavior is different than in RDS for MySQL 8.0, where the AUTO_INCREMENT value is preserved during these operations.

Temporary tables on reader DB instances

You can't create temporary tables using the InnoDB storage engine on Aurora MySQL reader instances. On reader instances, the InnoDB storage engine is configured as read-only. Make sure that any `CREATE TEMPORARY TABLE` statements on reader instances run with the `NO_ENGINE_SUBSTITUTION` SQL mode turned off.

The error that you receive is different depending on whether you use a plain `CREATE TEMPORARY TABLE` statement or the variation `CREATE TEMPORARY TABLE AS SELECT`. The following examples show the different kinds of errors.

This temporary table behavior only applies to read-only instances. This first example confirms that's the kind of instance the session is connected to.

```
mysql> select @@innodb_read_only;
+-----+
| @@innodb_read_only |
+-----+
|           1 |
+-----+
```

For plain `CREATE TEMPORARY TABLE` statements, the statement fails when the `NO_ENGINE_SUBSTITUTION` SQL mode is turned on. It succeeds when that SQL mode is turned off.

```
mysql> set sql_mode = 'NO_ENGINE_SUBSTITUTION';

mysql> CREATE TEMPORARY TABLE tt2 (id int) ENGINE=InnoDB;
ERROR 3161 (HY000): Storage engine InnoDB is disabled (Table creation is disallowed).

mysql> SET sql_mode = '';

mysql> CREATE TEMPORARY TABLE tt4 (id int) ENGINE=InnoDB;

mysql> SHOW CREATE TABLE tt4\G
***** 1. row *****
    Table: tt4
Create Table: CREATE TEMPORARY TABLE `tt4` (
  `id` int DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

For `CREATE TEMPORARY TABLE AS SELECT` statements, the statement fails whether or not the `NO_ENGINE_SUBSTITUTION` SQL mode is turned on. MySQL community edition doesn't support storage engine substitution with `CREATE TABLE AS SELECT` or `CREATE TEMPORARY TABLE AS SELECT` statements. For those statements, remove the `ENGINE=InnoDB` clause from your SQL code.

```
mysql> set sql_mode = 'NO_ENGINE_SUBSTITUTION';

mysql> CREATE TEMPORARY TABLE tt1 ENGINE=InnoDB AS SELECT * FROM t1;
ERROR 3161 (HY000): Storage engine InnoDB is disabled (Table creation is disallowed).

mysql> SET sql_mode = '';

mysql> CREATE TEMPORARY TABLE tt3 ENGINE=InnoDB AS SELECT * FROM t1;
ERROR 1874 (HY000): InnoDB is in read only mode.
```

Storage engine for internal temporary tables

In Aurora MySQL version 3, the way internal temporary tables work is different from earlier Aurora MySQL versions. Instead of choosing between the InnoDB and MyISAM storage engines for such temporary tables, now you choose between the `TempTable` and InnoDB storage engines.

With the `TempTable` storage engine, you can make an additional choice for how to handle certain data. The data affected overflows the memory pool that holds all the internal temporary tables for the DB instance.

Those choices can influence the performance for queries that generate high volumes of temporary data, for example while performing aggregations such as `GROUP BY` on large tables.

Tip

If your workload includes queries that generate internal temporary tables, confirm how your application performs with this change by running benchmarks and monitoring performance-related metrics.

In some cases, the amount of temporary data fits within the `TempTable` memory pool or only overflows the memory pool by a small amount. In these cases, we recommend using the `TempTable` setting for internal temporary tables and memory-mapped files to hold any overflow data. That setting is the default.

If a substantial amount of temporary data overflows the `TempTable` memory pool, we recommend using the `MEMORY` storage engine instead for internal temporary tables. Or you can choose `TempTable` for internal temporary tables and InnoDB tables to hold any overflow data.

You make the initial choice between the `TempTable` storage engine and the `MEMORY` storage engine for internal temporary tables. You do so by setting the parameter `internal_tmp_mem_storage_engine`. This parameter replaces the `internal_tmp_disk_storage_engine` parameter used in Aurora MySQL version 1 and 2.

The `TempTable` storage engine is the default. `TempTable` uses a common memory pool for all temporary tables that use this engine, instead of a maximum memory limit per table. The size of this memory pool is specified by the `temptable_max_ram` parameter. It defaults to 1 GB on DB instances with 16 or more GB of memory, and 16 MB on DB instances with less than 16 GB of memory. The size of the memory pool influences session-level memory consumption.

If you use the `TempTable` storage engine and the temporary data exceeds the size of the memory pool, Aurora MySQL stores the overflow data using a secondary mechanism.

You can set the parameters `temptable_use_mmap` and `temptable_max_mmap` to specify if the data overflows to memory-mapped temporary files or to InnoDB internal temporary tables on disk. The different data formats and overflow criteria of these overflow mechanisms can affect query performance. They do so by influencing the amount of data written to disk and the demand on disk storage throughput.

Aurora MySQL stores the overflow data differently depending on your choice of data overflow destination and whether the query runs on a writer or reader DB instance:

- On the writer instance, data that overflows to InnoDB internal temporary tables is stored in the Aurora cluster volume.
- On the writer instance, data that overflows to memory-mapped temporary files resides on local storage on the Aurora MySQL version 3 instance.
- On reader instances, overflow data always resides on memory-mapped temporary files on local storage. That's because read-only instances can't store any data on the Aurora cluster volume.

Note

The configuration parameters related to internal temporary tables apply differently to the writer and reader instances in your cluster. For reader instances, Aurora MySQL always uses the `TempTable` storage engine and a value of 1 for `temptable_use_mmap`. The size for `temptable_max_mmap` defaults to 1 GB, for both writer and reader instances, regardless of the DB instance memory size. You can adjust this value the same way as on the writer instance, except that you can't specify a value of zero for `temptable_max_mmap` on reader instances.

Binary log replication

In MySQL 8.0 community edition, binary log replication is turned on by default. In Aurora MySQL version 3, binary log replication is turned off by default.

Tip

If your high availability requirements are fulfilled by the Aurora built-in replication features, you can leave binary log replication turned off. That way, you can avoid the performance overhead of binary log replication. You can also avoid the associated monitoring and troubleshooting that are needed to manage binary log replication.

Aurora supports binary log replication from a MySQL 5.7-compatible source to Aurora MySQL version 3. The source system can be an Aurora MySQL DB cluster, an RDS for MySQL DB instance, or an on-premises MySQL instance.

As does community MySQL, Aurora MySQL supports replication from a source running a specific version to a target running the same major version or one major version higher. For example, replication from a MySQL 5.6-compatible system to Aurora MySQL version 3 isn't supported. Replicating from Aurora MySQL version 3 to a MySQL 5.7-compatible or MySQL 5.6-compatible system isn't supported. For details about using binary log replication, see [Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster \(binary log replication\) \(p. 932\)](#).

Aurora MySQL version 3 includes improvements to binary log replication in community MySQL 8.0, such as filtered replication. For details about the community MySQL 8.0 improvements, see [How Servers Evaluate Replication Filtering Rules](#) in the *MySQL Reference Manual*.

Multithreaded replication

With Aurora MySQL version 3, Aurora MySQL supports multithreaded replication. For usage information, see [Multithreaded binary log replication \(Aurora MySQL version 3 and higher\) \(p. 948\)](#).

Note

We still recommend not using multithreaded replication with Aurora MySQL version 1 and version 2.

Transaction compression for binary log replication

For usage information about binary log compression, see [Binary Log Transaction Compression](#) in the *MySQL Reference Manual*.

The following limitations apply to binary log compression in Aurora MySQL version 3:

- Transactions whose binary log data is larger than the maximum allowed packet size aren't compressed, regardless of whether the Aurora MySQL binary log compression setting is turned on. Such transactions are replicated without being compressed.
- If you use a connector for change data capture (CDC) that doesn't support MySQL 8.0 yet, you can't use this feature. We recommend that you test any third-party connectors thoroughly with binary log compression before turning on binlog compression on systems that use binlog replication for CDC.

Comparison of Aurora MySQL version 3 and community MySQL 8.0

You can use the following information to learn about the changes to be aware of when you convert from a different MySQL 8.0-compatible system to Aurora MySQL version 3.

In general, Aurora MySQL version 3 supports the feature set of community MySQL 8.0.23. Some new features from MySQL 8.0 community edition don't apply to Aurora MySQL. Some of those features aren't

compatible with some aspect of Aurora, such as the Aurora storage architecture. Other features aren't needed because the Amazon RDS management service provides equivalent functionality. The following features in community MySQL 8.0 aren't supported or work differently in Aurora MySQL version 3.

For release notes for all Aurora MySQL version 3 releases, see [Database engine updates for Amazon Aurora MySQL version 3 \(p. 1108\)](#).

Topics

- [MySQL 8.0 features not available in Aurora MySQL version 3 \(p. 757\)](#)
- [Role-based privilege model \(p. 757\)](#)
- [Authentication \(p. 760\)](#)

MySQL 8.0 features not available in Aurora MySQL version 3

The following features from community MySQL 8.0 aren't available or work differently in Aurora MySQL version 3.

- Resource groups and associated SQL statements aren't supported in Aurora MySQL.
- The Aurora storage architecture means that you don't have to manually manage files and the underlying storage for your database. In particular, Aurora handles the undo tablespace differently than community MySQL does. This difference from community MySQL has the following consequences:
 - Aurora MySQL doesn't support named tablespaces.
 - The `innodb_undo_log_truncate` configuration setting is turned off and can't be turned on. Aurora has its own mechanism for reclaiming storage space.
 - Aurora MySQL doesn't have the `CREATE UNDO TABLESPACE`, `ALTER UNDO TABLESPACE ... SET INACTIVE`, and `DROP UNDO TABLESPACE` statements.
 - Aurora sets the number of undo tablespaces automatically and manages those tablespaces for you.
- TLS 1.3 isn't supported in Aurora MySQL version 3.
- The `aurora_hot_page_contention` status variable isn't available. The hot page contention feature isn't supported. For the full list of status variables not available in Aurora MySQL version 3, see [Status variables \(p. 751\)](#).
- You can't modify the settings of any MySQL plugins.
- The X plugin isn't supported.

Role-based privilege model

With Aurora MySQL version 3, you can't modify the tables in the `mysql` database directly. In particular, you can't set up users by inserting into the `mysql.user` table. Instead, you use SQL statements to grant role-based privileges. You can still query the `mysql` tables. If you use binary log replication, changes made directly to the `mysql` tables on the source cluster aren't replicated to the target cluster.

In some cases, your application might use shortcuts to create users or other objects by inserting into the `mysql` tables. If so, change your application code to use the corresponding statements such as `CREATE USER`.

To export metadata for database users during the migration from an external MySQL database, you can use `mysqldump` command instead of `mysqldump`. Use the following syntax.

```
mysqldump --exclude-databases=mysql --users
```

This statement dumps all databases except for the tables in the `mysql` system database. It also includes `CREATE USER` and `GRANT` statements to reproduce all MySQL users in the migrated database. You can

also use the [pt-show-grants tool](#) on the source system to list CREATE USER and GRANT statements to reproduce all the database users.

To simplify managing permissions for many users or applications, you can use the CREATE ROLE statement to create a role that has a set of permissions. Then you can use the GRANT and SET ROLE statements and the `current_role` function to assign roles to users or applications, switch the current role, and check which roles are in effect. For more information on the role-based permission system in MySQL 8.0, see [Using Roles](#) in the MySQL Reference Manual.

Aurora MySQL version 3 includes a special role that has all of the following privileges. This role is named `rds_superuser_role`. The primary administrative user for each cluster already has this role granted. The `rds_superuser_role` role includes the following privileges for all database objects:

- `ALTER`
- `APPLICATION_PASSWORD_ADMIN`
- `ALTER ROUTINE`
- `CONNECTION_ADMIN`
- `CREATE`
- `CREATE ROLE`
- `CREATE ROUTINE`
- `CREATE TABLESPACE`
- `CREATE TEMPORARY TABLES`
- `CREATE USER`
- `CREATE VIEW`
- `DELETE`
- `DROP`
- `DROP ROLE`
- `EVENT`
- `EXECUTE`
- `INDEX`
- `INSERT`
- `LOCK TABLES`
- `PROCESS`
- `REFERENCES`
- `RELOAD`
- `REPLICATION CLIENT`
- `REPLICATION SLAVE`
- `ROLE_ADMIN`
- `SET_USER_ID`
- `SELECT`
- `SHOW DATABASES`
- `SHOW VIEW`
- `TRIGGER`
- `UPDATE`
- `XA_RECOVER_ADMIN`

The role definition also includes `WITH GRANT OPTION` so that an administrative user can grant that role to other users. In particular, the administrator must grant any privileges needed to perform binary log replication with the Aurora MySQL cluster as the target.

Tip

To see the full details of the permissions, enter the following statements.

```
SHOW GRANTS FOR rds_superuser_role@'%';
SHOW GRANTS FOR name_of_administrative_user_for_your_cluster@'%';
```

Aurora MySQL version 3 also includes roles that you can use to access other AWS services. You can set these roles as an alternative to GRANT statements. For example, you specify GRANT AWS_LAMBDA_ACCESS TO *user* instead of GRANT INVOKE LAMBDA ON *.* TO *user*. For the procedures to access other AWS services, see [Integrating Amazon Aurora MySQL with other AWS services \(p. 984\)](#). Aurora MySQL version 3 includes the following roles related to accessing other AWS services:

- AWS_LAMBDA_ACCESS role, as an alternative to the INVOKE LAMBDA privilege. For usage information, see [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster \(p. 1010\)](#).
- AWS_LOAD_S3_ACCESS role, as an alternative to the LOAD FROM S3 privilege. For usage information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket \(p. 997\)](#).
- AWS_SELECT_S3_ACCESS role, as an alternative to the SELECT INTO S3 privilege. For usage information, see [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket \(p. 1004\)](#).
- AWS_SAGEMAKER_ACCESS role, as an alternative to the INVOKE SAGEMAKER privilege. For usage information, see [Using machine learning \(ML\) with Aurora MySQL \(p. 1020\)](#).
- AWS_COMPREHEND_ACCESS role, as an alternative to the INVOKE COMPREHEND privilege. For usage information, see [Using machine learning \(ML\) with Aurora MySQL \(p. 1020\)](#).

When you grant access by using roles in Aurora MySQL version 3, you also activate the role by using the SET ROLE *role_name* or SET ROLE ALL statement. The following example shows how. Substitute the appropriate role name for AWS_SELECT_S3_ACCESS.

```
# Grant role to user
mysql> GRANT AWS_SELECT_S3_ACCESS TO 'user'@'domain-or-ip-address'

# Check the current roles for your user. In this case, the AWS_SELECT_S3_ACCESS role has
# not been activated.
# Only the rds_superuser_role is currently in effect.
mysql> SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE()          |
+-----+
| `rds_superuser_role`@`%` |
+-----+
1 row in set (0.00 sec)

# Activate all roles associated with this user using SET ROLE.
# You can activate specific roles or all roles.
# In this case, the user only has 2 roles, so we specify ALL.
mysql> SET ROLE ALL;
Query OK, 0 rows affected (0.00 sec)

# Verify role is now active
mysql> SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE()          |
+-----+
| `AWS_LAMBDA_ACCESS`@`%`, `rds_superuser_role`@`%` |
+-----+
```

Authentication

In community MySQL 8.0, the default authentication plugin is `caching_sha2_password`. Aurora MySQL version 3 still uses the `mysql_native_password` plugin. You can't change the `default_authentication_plugin` setting.

Upgrading to Aurora MySQL version 3

For specific upgrade paths to upgrade your database from Aurora MySQL version 1 or 2 to version 3, you can use one of the following approaches:

- To upgrade an Aurora MySQL version 2 cluster to version 3, create a snapshot of the version 2 cluster and restore the snapshot to create a new version 3 cluster. Follow the procedure in [Restoring from a DB cluster snapshot \(p. 497\)](#). Currently, in-place upgrade isn't available from Aurora MySQL version 2 to Aurora MySQL version 3.
- To upgrade from Aurora MySQL version 1, first do an intermediate upgrade to Aurora MySQL version 2. To do the upgrade to Aurora MySQL version 2, use any of the upgrade methods in [Upgrading Amazon Aurora MySQL DB clusters \(p. 1088\)](#). Then use the snapshot restore technique to upgrade from Aurora MySQL version 2 to Aurora MySQL version 3. Snapshot restore isn't available from Aurora MySQL version 1 clusters (MySQL 5.6-compatible) to Aurora MySQL version 3.
- Currently, you can't clone a MySQL 5.7-compatible Aurora cluster to a MySQL 8.0-compatible one. Use the snapshot restore technique instead.
- If you have an Aurora MySQL version 2 cluster that uses backtrack, currently you can't use the snapshot restore method to upgrade to Aurora MySQL version 3. This limitation applies to all clusters that use backtrack, regardless of whether the backtrack setting is turned on. In this case, perform a logical dump and restore by using a tool such as the `mysqldump` command. For more information about using `mysqldump` for Aurora MySQL, see [Migrating from MySQL to Amazon Aurora by using mysqldump \(p. 796\)](#).

Tip

In some cases, you might specify the option to upload database logs to CloudWatch when you restore the snapshot. If so, examine the logs in CloudWatch to diagnose any issues that occur during the restore and associated upgrade operation. The CLI examples in this section demonstrate how to do so using the `--enable-cloudwatch-logs-exports` option.

Topics

- [Upgrade planning for Aurora MySQL version 3 \(p. 760\)](#)
- [Example of upgrading from Aurora MySQL version 2 to version 3 \(p. 761\)](#)
- [Example of upgrading from Aurora MySQL version 1 to version 3 \(p. 763\)](#)
- [Troubleshooting upgrade issues with Aurora MySQL version 3 \(p. 765\)](#)
- [Post-upgrade cleanup for Aurora MySQL version 3 \(p. 772\)](#)

Upgrade planning for Aurora MySQL version 3

To help you decide the right time and approach to upgrade, you can learn the differences between Aurora MySQL version 3 and your current Aurora and MySQL environment:

- If you are converting from RDS for MySQL 8.0 or community MySQL 8.0, see [Comparison of Aurora MySQL version 3 and community MySQL 8.0 \(p. 756\)](#).
- If you are upgrading from Aurora MySQL version 2, RDS for MySQL 5.7, or community MySQL 5.7, see [Comparison of Aurora MySQL version 2 and Aurora MySQL version 3 \(p. 749\)](#).
- Create new MySQL 8.0-compatible versions of any custom parameter groups. Apply any necessary custom parameter values to the new parameter groups. Consult [Parameter changes for Aurora MySQL version 3 \(p. 751\)](#) to learn about parameter changes.

Note

For most parameter settings, you can choose the custom parameter group either when you create the cluster or associate the parameter group with the cluster later. However, if you use a nondefault setting for the `lower_case_table_names` parameter, you must set up the custom parameter group with this setting in advance. Then specify the parameter group when you perform the snapshot restore to create the cluster. Any change to the `lower_case_table_names` parameter has no effect after the cluster is created.

You can also find more MySQL-specific upgrade considerations and tips in [Changes in MySQL 8.0](#) in the *MySQL Reference Manual*. For example, you can use the command `mysqlcheck --check-upgrade` to analyze your existing Aurora MySQL databases and identify potential upgrade issues.

Currently, the primary upgrade path from earlier Aurora MySQL versions to Aurora MySQL version 3 is by restoring a snapshot to create a new cluster. You can restore a snapshot of a cluster running any minor version of Aurora MySQL version 2 (MySQL 5.7-compatible) to Aurora MySQL version 3. To upgrade from Aurora MySQL version 1, you use a two-step process. First restore a snapshot to an Aurora MySQL version 2 cluster, then make a snapshot of that cluster and restore it to an Aurora MySQL version 3 cluster. For the upgrade procedure from Aurora MySQL version 1 or 2, see [Upgrading to Aurora MySQL version 3 \(p. 760\)](#). For general information about upgrading by restoring a snapshot, see [Upgrading Amazon Aurora MySQL DB clusters \(p. 1088\)](#).

After you finish the upgrade itself, you can follow the post-upgrade procedures in [Post-upgrade cleanup for Aurora MySQL version 3 \(p. 772\)](#). Finally, test your application's functionality and performance.

If you are converting from RDS from MySQL or community MySQL, follow the migration procedure explained in [Migrating data to an Amazon Aurora MySQL DB cluster \(p. 781\)](#). In some cases, you might use binary log replication to synchronize your data with an Aurora MySQL version 3 cluster as part of the migration. If so, the source system must run a version that's compatible with MySQL 5.7, or a MySQL 8.0-compatible version that is 8.0.23 or lower.

Example of upgrading from Aurora MySQL version 2 to version 3

The following AWS CLI example demonstrates the steps to upgrade an Aurora MySQL version 2 cluster to Aurora MySQL version 3.

The first step is to determine the version of the cluster that you want to upgrade. The following AWS CLI command shows how. The output confirms that the original cluster is a MySQL 5.7-compatible one that's running Aurora MySQL version 2.09.2.

This cluster has at least one DB instance. For the upgrade process to work properly, this original cluster requires a writer instance.

```
$ aws rds describe-db-clusters --db-cluster-id cluster-57-upgrade-ok \
--query '*[].EngineVersion' --output text
5.7.mysql_aurora.2.09.2
```

The following command shows how to check which upgrade paths are available from a specific version. In this case, the original cluster is running version 5.7.mysql_aurora.2.09.2. The output shows that this version can be upgraded to Aurora MySQL version 3.

If the original cluster uses a version number that is too low to upgrade to Aurora MySQL version 3, the upgrade requires an additional step. First, restore the snapshot to create a new cluster that could be upgraded to Aurora MySQL version 3. Then, take a snapshot of that intermediate cluster. Finally, restore the snapshot of the intermediate cluster to create a new Aurora MySQL version 3 cluster.

```
$ aws rds describe-db-engine-versions --engine aurora-mysql \
```

```
--engine-version 5.7.mysql_aurora.2.09.2 \
--query 'DBEngineVersions[ ].ValidUpgradeTarget[ ].EngineVersion'
[
    "5.7.mysql_aurora.2.10.0",
    "5.7.mysql_aurora.2.10.1",
    "8.0.mysql_aurora.3.01.0"
]
```

The following command creates a snapshot of the cluster to upgrade to Aurora MySQL version 3. The original cluster remains intact. You later create a new Aurora MySQL version 3 cluster from the snapshot.

```
aws rds create-db-cluster-snapshot --db-cluster-id cluster-57-upgrade-ok \
--db-cluster-snapshot-id cluster-57-upgrade-ok-snapshot
{
    "DBClusterSnapshotIdentifier": "cluster-57-upgrade-ok-snapshot",
    "DBClusterIdentifier": "cluster-57-upgrade-ok",
    "SnapshotCreateTime": "2021-10-06T23:20:18.087000+00:00"
}
```

The following command restores the snapshot to a new cluster that's running Aurora MySQL version 3.

```
$ aws rds restore-db-cluster-from-snapshot \
--snapshot-id cluster-57-upgrade-ok-snapshot \
--db-cluster-id cluster-80-restored --engine aurora-mysql \
--engine-version 8.0.mysql_aurora.3.01.0 \
--enable-cloudwatch-logs-exports '[{"error", "general", "slowquery", "audit"}]'
{
    "DBClusterIdentifier": "cluster-80-restored",
    "Engine": "aurora-mysql",
    "EngineVersion": "8.0.mysql_aurora.3.01.0",
    "Status": "creating"
}
```

Restoring the snapshot sets up the storage for the cluster and establishes the database version that the cluster can use. Because the compute capacity of the cluster is separate from the storage, you set up any DB instances for the cluster once the cluster itself is created. The following example creates a writer DB instance using one of the db.r5 instance classes.

Tip

You might have administration scripts that create DB instances using older instance classes such as db.r3, db.r4, db.t2, or db.t3. If so, modify your scripts to use one of the instance classes that are supported with Aurora MySQL version 3. For information about the instance classes that you can use with Aurora MySQL version 3, see [Instance class support \(p. 750\)](#).

```
$ aws rds create-db-instance --db-instance-identifier instance-running-version-3 \
--db-cluster-identifier cluster-80-restored \
--db-instance-class db.r5.xlarge --engine aurora-mysql
{
    "DBInstanceIdentifier": "instance-running-version-3",
    "DBClusterIdentifier": "cluster-80-restored",
    "DBInstanceClass": "db.r5.xlarge",
    "EngineVersion": "8.0.mysql_aurora.3.01.0",
    "DBInstanceStatus": "creating"
}
```

After the upgrade is finished, you can verify the Aurora-specific version number of the cluster by using the AWS CLI.

```
$ aws rds describe-db-clusters --db-cluster-id cluster-80-restored \
--query '*[ ].EngineVersion' --output text
```

```
8.0.mysql_aurora.3.01.0
```

You can also verify the MySQL-specific version of the database engine by calling the `version` function.

```
mysql> select version();
+-----+
| version() |
+-----+
| 8.0.23   |
+-----+
```

Example of upgrading from Aurora MySQL version 1 to version 3

The following example shows the two-stage upgrade process if the original snapshot is from a version that can't be directly restored to Aurora MySQL version 3. Instead, that snapshot is restored to a cluster running an intermediate version that you can upgrade to Aurora MySQL version 3. This intermediate cluster doesn't need any associated DB instances. Then, another snapshot is created from the intermediate cluster. Finally, the second snapshot is restored to create a new Aurora MySQL version 3 cluster and a writer DB instance.

The Aurora MySQL version 1 cluster that we start with is named `aurora-mysql-v1-to-v2`. It's running Aurora MySQL version 1.23.4. It has at least one DB instance in the cluster.

This example checks which Aurora MySQL version 2 versions can be upgraded to the `8.0.mysql_aurora.3.01.0` to use on the upgraded cluster. For this example, we choose version 2.10.0 as the intermediate version.

```
$ aws rds describe-db-engine-versions --engine aurora-mysql \
--query '*[]'.
{EngineVersion:EngineVersion,TargetVersions:ValidUpgradeTarget[*].EngineVersion} | \
[?contains(TargetVersions, `'8.0.mysql_aurora.3.01.0'`) == `true`]|[].EngineVersion' \
--output text
...
5.7.mysql_aurora.2.08.3
5.7.mysql_aurora.2.09.1
5.7.mysql_aurora.2.09.2
5.7.mysql_aurora.2.10.0
...
```

The following example verifies that Aurora MySQL version 1.23.4 to 2.10.0 is an available upgrade path. Thus, the Aurora MySQL version that we're running can be upgraded to 2.10.0. Then that cluster can be upgraded to 3.01.0.

```
aws rds describe-db-engine-versions --engine aurora \
--query '*[]'.
{EngineVersion:EngineVersion,TargetVersions:ValidUpgradeTarget[*].EngineVersion} | \
[?contains(TargetVersions, `'5.7.mysql_aurora.2.10.0'`) == `true`]|[].EngineVersion' \
--output text
...
5.6.mysql_aurora.1.22.5
5.6.mysql_aurora.1.23.0
5.6.mysql_aurora.1.23.1
5.6.mysql_aurora.1.23.2
5.6.mysql_aurora.1.23.3
5.6.mysql_aurora.1.23.4
...
```

The following example creates a snapshot named `aurora-mysql-v1-to-v2-snapshot` that's based on the original Aurora MySQL version 1 cluster.

```
$ aws rds create-db-cluster-snapshot \
--db-cluster-id aurora-mysql-v1-to-v2 \
--db-cluster-snapshot-id aurora-mysql-v1-to-v2-snapshot
{
  "DBClusterSnapshotIdentifier": "aurora-mysql-v1-to-v2-snapshot",
  "DBClusterIdentifier": "aurora-mysql-v1-to-v2"
}
```

The following example creates the intermediate Aurora MySQL version 2 cluster from the version 1 snapshot. This intermediate cluster is named `aurora-mysql-v2-to-v3`. It's running Aurora MySQL version 2.10.0.

The example also creates a writer instance for the cluster. For the upgrade process to work properly, this intermediate cluster requires a writer instance.

```
$ aws rds restore-db-cluster-from-snapshot \
--snapshot-id aurora-mysql-v1-to-v2-snapshot \
--db-cluster-id aurora-mysql-v2-to-v3 \
--engine aurora-mysql --engine-version 5.7.mysql_aurora.2.10.0 \
--enable-cloudwatch-logs-exports '[{"error","general","slowquery","audit"}'
{
  "DBCluster": {
    "AllocatedStorage": 1,
    "AvailabilityZones": [
      "us-east-1a",
      "us-east-1d",
      "us-east-1f"
    ],
    ...
  }
}

$ aws rds create-db-instance --db-instance-identifier upgrade-demo-instance \
--db-cluster-identifier aurora-mysql-v2-to-v3 \
--db-instance-class db.r5.xlarge \
--engine aurora-mysql
{
  "DBInstanceIdentifier": "upgrade-demo-instance",
  "DBInstanceClass": "db.r5.xlarge",
  "DBInstanceState": "creating"
}
```

The following example creates a snapshot from the intermediate Aurora MySQL version 2 cluster. This snapshot is named `aurora-mysql-v2-to-v3-snapshot`. This is the snapshot to be restored to create the Aurora MySQL version 3 cluster.

```
$ aws rds create-db-cluster-snapshot \
--db-cluster-id aurora-mysql-v2-to-v3 \
--db-cluster-snapshot-id aurora-mysql-v2-to-v3-snapshot
{
  "DBClusterSnapshotIdentifier": "aurora-mysql-v2-to-v3-snapshot",
  "DBClusterIdentifier": "aurora-mysql-v2-to-v3"
}
```

The following command creates the Aurora MySQL version 3 cluster. This cluster is named `aurora-mysql-v3-fully-upgraded`.

```
$ aws rds restore-db-cluster-from-snapshot \
--snapshot-id aurora-mysql-v2-to-v3-snapshot \
--db-cluster-id aurora-mysql-v3-fully-upgraded \
--engine aurora-mysql --engine-version 8.0.mysql_aurora.3.01.0 \
--enable-cloudwatch-logs-exports '[{"error","general","slowquery","audit"}']
```

```
{  
    "DBCluster": {  
        "AllocatedStorage": 1,  
        "AvailabilityZones": [  
            "us-east-1b",  
            "us-east-1c",  
            "us-east-1d"  
        ],  
        ...  
    },
```

Now that the Aurora MySQL version 3 cluster is created, the following example creates a writer DB instance for it. When the cluster and the writer instance become available, you can connect to the cluster and begin using it. All of the data from the original cluster is preserved through each of the snapshot stages.

```
$ aws rds create-db-instance \  
  --db-instance-identifier instance-also-running-v3 \  
  --db-cluster-identifier aurora-mysql-v3-fully-upgraded \  
  --db-instance-class db.r5.xlarge --engine aurora-mysql  
{  
    "DBInstanceIdentifier": "instance-also-running-v3",  
    "DBClusterIdentifier": "aurora-mysql-v3-fully-upgraded",  
    "DBInstanceClass": "db.r5.xlarge",  
    "EngineVersion": "8.0.mysql_aurora.3.01.0",  
    "DBInstanceState": "creating"  
}
```

Troubleshooting upgrade issues with Aurora MySQL version 3

If your upgrade to Aurora MySQL version 3 doesn't complete successfully, you can diagnose the cause of the problem. Then you can make any required changes to the original database schema or table data and run the upgrade process again.

If the upgrade process to Aurora MySQL version 3 fails, the problem is detected while creating and then upgrading the writer instance for the restored snapshot. Aurora leaves behind the original 5.7-compatible writer instance. That way, you can examine the log from the preliminary checks that Aurora runs before performing the upgrade. The following examples start with a 5.7-compatible database that requires some changes before it can be upgraded to Aurora MySQL version 3. The examples demonstrate how the first attempted upgrade doesn't succeed, how to examine the log file, and how to fix the problems and run a successful upgrade.

First, we create a new MySQL 5.7-compatible cluster named `problematic-57-80-upgrade`. As the name suggests, this cluster contains at least one schema object that causes a problem during an upgrade to a MySQL 8.0-compatible version.

```
$ aws rds create-db-cluster --engine aurora-mysql \  
  --engine-version 5.7.mysql_aurora.2.10.0 \  
  --db-cluster-identifier problematic-57-80-upgrade \  
  --master-username my_username \  
  --master-user-password my_password  
{  
    "DBClusterIdentifier": "problematic-57-80-upgrade",  
    "Status": "creating"  
}  
  
$ aws rds create-db-instance \  
  --db-instance-identifier instance-preupgrade \  
  --db-cluster-identifier problematic-57-80-upgrade \  
  --db-instance-class db.t2.small --engine aurora-mysql  
{  
    "DBInstanceIdentifier": "instance-preupgrade",
```

```

        "DBClusterIdentifier": "problematic-57-80-upgrade",
        "DBInstanceClass": "db.t2.small",
        "DBInstanceState": "creating"
    }

$ aws rds wait db-instance-available \
--db-instance-identifier instance-preupgrade

```

In the cluster that we intend to upgrade, we introduce a problematic table. Creating a `FULLTEXT` index and then dropping the index leaves behind some metadata that causes a problem during the upgrade.

```

$ mysql -u my_username -p \
-h problematic-57-80-upgrade.cluster-example123.us-east-1.rds.amazonaws.com

mysql> create database problematic_upgrade;
Query OK, 1 row affected (0.02 sec)

mysql> use problematic_upgrade;
Database changed
mysql> CREATE TABLE dangling_fulltext_index
    -> (id INT AUTO_INCREMENT PRIMARY KEY, txtcol TEXT NOT NULL)
    -> ENGINE=InnoDB;
Query OK, 0 rows affected (0.05 sec)

mysql> ALTER TABLE dangling_fulltext_index ADD FULLTEXT(txtcol);
Query OK, 0 rows affected, 1 warning (0.14 sec)

mysql> ALTER TABLE dangling_fulltext_index DROP INDEX txtcol;
Query OK, 0 rows affected (0.06 sec)

```

This example attempts to perform the upgrade procedure. We take a snapshot of the original cluster and wait for snapshot creation to complete. Then we restore the snapshot, specifying the MySQL 8.0-compatible version number. We also create the writer instance for the cluster. That is the point where the upgrade processing actually happens. Then we wait for the writer instance to become available. That's the point where the upgrade process is finished, whether it succeeded or failed.

Tip

If you restore the snapshot using the AWS Management Console, Aurora creates the writer instance automatically and upgrades it to the requested engine version.

```

$ aws rds create-db-cluster-snapshot --db-cluster-id problematic-57-80-upgrade \
--db-cluster-snapshot-id problematic-57-80-upgrade-snapshot
{
    "DBClusterSnapshotIdentifier": "problematic-57-80-upgrade-snapshot",
    "DBClusterIdentifier": "problematic-57-80-upgrade",
    "Engine": "aurora-mysql",
    "EngineVersion": "5.7.mysql_aurora.2.10.0"
}

$ aws rds wait db-cluster-snapshot-available \
--db-cluster-snapshot-id problematic-57-80-upgrade-snapshot

$ aws rds restore-db-cluster-from-snapshot \
--snapshot-id problematic-57-80-upgrade-snapshot \
--db-cluster-id cluster-80-attempt-1 --engine aurora-mysql \
--engine-version 8.0.mysql_aurora.3.01.0 \
--enable-cloudwatch-logs-exports '["error","general","slowquery","audit"]'
{
    "DBClusterIdentifier": "cluster-80-attempt-1",
    "Engine": "aurora-mysql",
    "EngineVersion": "8.0.mysql_aurora.3.01.0",
    "Status": "creating"
}

```

```
$ aws rds create-db-instance --db-instance-identifier instance-attempt-1 \
--db-cluster-identifier cluster-80-attempt-1 \
--db-instance-class db.r5.xlarge --engine aurora-mysql
{
    "DBInstanceIdentifier": "instance-attempt-1",
    "DBClusterIdentifier": "cluster-80-attempt-1",
    "DBInstanceClass": "db.r5.xlarge",
    "EngineVersion": "8.0.mysql_aurora.3.01.0",
    "DBInstanceState": "creating"
}

$ aws rds wait db-instance-available \
--db-instance-identifier instance-attempt-1
```

Now we examine the newly created cluster and associated instance to verify if the upgrade succeeded. The cluster and instance are still running a MySQL 5.7-compatible version. That means that the upgrade failed. When an upgrade fails, Aurora only leaves the writer instance behind so that you can examine any log files. You can't restart the upgrade process with that newly created cluster. After you correct the problem by making changes in your original cluster, you must run the upgrade steps again: make a new snapshot of the original cluster and restore it to another MySQL 8.0-compatible cluster.

```
$ aws rds describe-db-clusters \
--db-cluster-identifier cluster-80-attempt-1 \
--query '*[].[Status]' --output text
available
$ aws rds describe-db-clusters \
--db-cluster-identifier cluster-80-attempt-1 \
--query '*[].[EngineVersion]' --output text
5.7.mysql_aurora.2.10.0

$ aws rds describe-db-instances \
--db-instance-identifier instance-attempt-1 \
--query '*[].[{DBInstanceState:DBInstanceState}]' --output text
available
$ aws rds describe-db-instances \
--db-instance-identifier instance-attempt-1 \
--query '*[].[EngineVersion]' --output text
5.7.mysql_aurora.2.10.0
```

To get a summary of what happened during the upgrade process, we get a listing of events for the newly created writer instance. In this example, we list the events over the last 600 minutes to cover the whole time interval of the upgrade process. The events in the listing aren't necessarily in chronological order. The highlighted event shows the problem that confirms the cluster couldn't be upgraded.

```
$ aws rds describe-events \
--source-identifier instance-attempt-1 --source-type db-instance \
--duration 600
{
    "Events": [
        {
            "SourceIdentifier": "instance-attempt-1",
            "SourceType": "db-instance",
            "Message": "Binlog position from crash recovery is mysql-bin-changelog.000001
154",
            "EventCategories": [],
            "Date": "2021-12-03T20:26:17.862000+00:00",
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:instance-attempt-1"
        },
        {
            "SourceIdentifier": "instance-attempt-1",
            "SourceType": "db-instance",
            "Message": "Binlog position from crash recovery is mysql-bin-changelog.000001
155",
            "EventCategories": [],
            "Date": "2021-12-03T20:26:17.862000+00:00",
            "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:instance-attempt-1"
        }
    ]
}
```

```

    "Message": "Database cluster is in a state that cannot be upgraded:
PreUpgrade checks failed: Oscar PreChecker Found 1 errors",
    "EventCategories": [
        "maintenance"
    ],
    "Date": "2021-12-03T20:26:50.436000+00:00",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:instance-attempt-1"
},
{
    "SourceIdentifier": "instance-attempt-1",
    "SourceType": "db-instance",
    "Message": "DB instance created",
    "EventCategories": [
        "creation"
    ],
    "Date": "2021-12-03T20:26:58.830000+00:00",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:instance-attempt-1"
},
...

```

To diagnose the exact cause of the problem, examine the database logs for the newly created writer instance. When an upgrade to an 8.0-compatible version fails, the instance contains a log file with the file name `upgrade-prechecks.log`. This example shows how to detect the presence of that log and then download it to a local file for examination.

```

$ aws rds describe-db-log-files --db-instance-identifier instance-attempt-1 \
--query '*[].[LogFileName]' --output text
error/mysql-error-running.log
error/mysql-error-running.log.2021-12-03.20
error/mysql-error-running.log.2021-12-03.21
error/mysql-error.log
external/mysql-external.log
upgrade-prechecks.log

$ aws rds download-db-log-file-portion --db-instance-identifier instance-attempt-1 \
--log-file-name upgrade-prechecks.log --starting-token 0 \
--output text >upgrade_prechecks.log

```

The `upgrade-prechecks.log` file is in JSON format. We download it using the `--output text` option to avoid encoding JSON output within another JSON wrapper. For Aurora MySQL version 3 upgrades, this log always includes certain informational and warning messages. It only includes error messages if the upgrade fails. If the upgrade succeeds, the log file isn't produced at all. The following excerpts show the kinds of entries you can expect to find.

```

$ cat upgrade-prechecks.log
{
    "serverAddress": "/tmp%2Fmysql.sock",
    "serverVersion": "5.7.12",
    "targetVersion": "8.0.23",
    "auroraServerVersion": "2.10.0",
    "auroraTargetVersion": "3.01.0",
    "outfilePath": "/rdsdbdata/tmp/PreChecker.log",
    "checksPerformed": [

```

If `"detectedProblems"` is empty, the upgrade didn't encounter any occurrences of that type of problem. You can ignore those entries.

```

{
    "id": "oldTemporalCheck",
    "title": "Usage of old temporal type",
    "status": "OK",

```

```
    "detectedProblems": []
},
```

Checks for removed variables or changed default values aren't performed automatically. Aurora uses the parameter group mechanism instead of a physical configuration file. You always receive some messages with this `CONFIGURATION_ERROR` status, whether or not the variable changes have any effect on your database. You can consult the MySQL documentation for details about these changes.

```
{
  "id": "removedSysLogVars",
  "title": "Removed system variables for error logging to the system log configuration",
  "status": "CONFIGURATION_ERROR",
  "description": "To run this check requires full path to MySQL server configuration file to be specified at 'configPath' key of options dictionary",
  "documentationLink": "https://dev.mysql.com/doc/relnotes/mysql/8.0/en/news-8-0-13.html#mysqld-8-0-13-logging"
},
```

This warning about obsolete date and time data types occurs if the `SQL_MODE` setting in your parameter group is left at the default value. Your database might or might not contain columns with the affected types.

```
{
  "id": "zeroDatesCheck",
  "title": "Zero Date, Datetime, and Timestamp values",
  "status": "OK",
  "description": "Warning: By default zero date/datetime/timestamp values are no longer allowed in MySQL, as of 5.7.8 NO_ZERO_IN_DATE and NO_ZERO_DATE are included in SQL_MODE by default. These modes should be used with strict mode as they will be merged with strict mode in a future release. If you do not include these modes in your SQL_MODE setting, you are able to insert date/datetime/timestamp values that contain zeros. It is strongly advised to replace zero values with valid ones, as they may not work correctly in the future.",
  "documentationLink": "https://lefred.be/content/mysql-8-0-and-wrong-dates/",
  "detectedProblems": [
    {
      "level": "Warning",
      "dbObject": "global.sql_mode",
      "description": "does not contain either NO_ZERO_DATE or NO_ZERO_IN_DATE which allows insertion of zero dates"
    }
  ]
},
```

When the `detectedProblems` field contains entries with a `level` value of `Error`, that means that the upgrade can't succeed until you correct those issues.

```
{
  "id": "getDanglingFulltextIndex",
  "title": "Tables with dangling FULLTEXT index reference",
  "status": "OK",
  "description": "Error: The following tables contain dangling FULLTEXT index which is not supported. It is recommended to rebuild the table before upgrade.",
  "detectedProblems": [
    {
      "level": "Error",
      "dbObject": "problematic_upgrade.dangling_fulltext_index",
      "description": "Table `problematic_upgrade.dangling_fulltext_index` contains dangling FULLTEXT index. Kindly recreate the table before upgrade."
    }
  ]
},
```

```
        }
    ],
},
```

Tip

To summarize all of those errors and display the associated object and description fields, you can run the command `grep -A 2 '"level": "Error"` on the contents of the `upgrade-prechecks.log` file. Doing so displays each error line and the two lines after it, which contain the name of the corresponding database object and guidance about how to correct the problem.

```
$ cat upgrade-prechecks.log | grep -A 2 '"level": "Error"'
"level": "Error",
"dbObject": "problematic_upgrade.dangling_fulltext_index",
"description": "Table `problematic_upgrade.dangling_fulltext_index` contains
dangling FULLTEXT index. Kindly recreate the table before upgrade."
```

This `defaultAuthenticationPlugin` check always displays this warning message for Aurora MySQL version 3 upgrades. That's because Aurora MySQL version 3 uses the `mysql_native_password` plugin instead of `caching_sha2_password`. You don't need to take any action for this warning.

```
{
  "id": "defaultAuthenticationPlugin",
  "title": "New default authentication plugin considerations",
  "description": "Warning: The new default authentication plugin
'caching_sha2_password' offers more secure password hashing than previously
used 'mysql_native_password' (and consequent improved client connection
...
  "documentationLink": "https://dev.mysql.com/doc/refman/8.0/en/upgrading-from-previous-
series.html#upgrade-caching-sha2-password-compatibility-issues\nhttps://dev.mysql.com/
doc/refman/8.0/en/upgrading-from-previous-series.html#upgrade-caching-sha2-password-
replication"
}
```

The end of the `upgrade-prechecks.log` file summarizes how many checks encountered each type of minor or severe problem. A nonzero `errorCount` indicates that the upgrade failed.

```
],
  "errorCount": 1,
  "warningCount": 2,
  "noticeCount": 0,
  "Summary": "1 errors were found. Please correct these issues before
upgrading to avoid compatibility issues."
}
```

The next sequence of examples demonstrates how to fix this particular issue and run the upgrade process again. This time, the upgrade succeeds.

First, we go back to the original cluster and create a new table with the same structure and contents as the one with faulty metadata. In practice, you would probably rename this table back to the original table name after the upgrade.

```
$ mysql -u my_username -p \
-h problematic-57-80-upgrade.cluster-example123.us-east-1.rds.amazonaws.com

mysql> show databases;
+-----+
| Database      |
+-----+
| information_schema |
```

```

| mysql          |
| performance_schema |
| problematic_upgrade |
| sys            |
+-----+
5 rows in set (0.00 sec)

mysql> use problematic_upgrade;
mysql> show tables;
+-----+
| Tables_in_problematic_upgrade |
+-----+
| dangling_fulltext_index        |
+-----+
1 row in set (0.00 sec)

mysql> desc dangling_fulltext_index;
+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra       |
+-----+-----+-----+-----+-----+
| id    | int(11) | NO   | PRI | NULL    | auto_increment |
| txtcol | text    | NO   |     | NULL    |               |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE recreated_table LIKE dangling_fulltext_index;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO recreated_table SELECT * FROM dangling_fulltext_index;
Query OK, 0 rows affected (0.00 sec)

mysql> drop table dangling_fulltext_index;
Query OK, 0 rows affected (0.05 sec)

```

Now we go through the same process as before: creating a snapshot from the original cluster, restoring the snapshot to a new MySQL 8.0-compatible cluster, and creating a writer instance to complete the upgrade process.

```

$ aws rds create-db-cluster-snapshot --db-cluster-id problematic-57-80-upgrade \
--db-cluster-snapshot-id problematic-57-80-upgrade-snapshot-2
{
  "DBClusterSnapshotIdentifier": "problematic-57-80-upgrade-snapshot-2",
  "DBClusterIdentifier": "problematic-57-80-upgrade",
  "Engine": "aurora-mysql",
  "EngineVersion": "5.7.mysql_aurora.2.10.0"
}

$ aws rds wait db-cluster-snapshot-available \
--db-cluster-snapshot-id problematic-57-80-upgrade-snapshot-2

$ aws rds restore-db-cluster-from-snapshot \
--snapshot-id problematic-57-80-upgrade-snapshot-2 \
--db-cluster-id cluster-80-attempt-2 --engine aurora-mysql \
--engine-version 8.0.mysql_aurora.3.01.0 \
--enable-cloudwatch-logs-exports '[{"error", "general", "slowquery", "audit"}]'
{
  "DBClusterIdentifier": "cluster-80-attempt-2",
  "Engine": "aurora-mysql",
  "EngineVersion": "8.0.mysql_aurora.3.01.0",
  "Status": "creating"
}

$ aws rds create-db-instance --db-instance-identifier instance-attempt-2 \
--db-cluster-identifier cluster-80-attempt-2 \

```

```
--db-instance-class db.r5.xlarge --engine aurora-mysql
{
    "DBInstanceIdentifier": "instance-attempt-2",
    "DBClusterIdentifier": "cluster-80-attempt-2",
    "DBInstanceClass": "db.r5.xlarge",
    "EngineVersion": "8.0.mysql_aurora.3.01.0",
    "DBInstanceState": "creating"
}

$ aws rds wait db-instance-available \
--db-instance-identifier instance-attempt-2
```

This time, checking the version after the upgrade completes confirms that the version number changed to reflect Aurora MySQL version 3. We can connect to the database and confirm the MySQL engine version is an 8.0-compatible one. We confirm that the upgraded cluster contains the fixed version of the table that caused the original upgrade problem.

```
$ aws rds describe-db-clusters \
--db-cluster-identifier cluster-80-attempt-2 \
--query '*[].[EngineVersion]' --output text
8.0.mysql_aurora.3.01.0
$ aws rds describe-db-instances \
--db-instance-identifier instance-attempt-2 \
--query '*[].[EngineVersion]' --output text
8.0.mysql_aurora.3.01.0

$ mysql -h cluster-80-attempt-2.cluster-example123.us-east-1.rds.amazonaws.com \
-u my_username -p

mysql> select version();
+-----+
| version() |
+-----+
| 8.0.23   |
+-----+
1 row in set (0.00 sec)

mysql> show databases;
+-----+
| Database      |
+-----+
| information_schema |
| mysql          |
| performance_schema |
| problematic_upgrade |
| sys            |
+-----+
5 rows in set (0.00 sec)

mysql> use problematic_upgrade;
Database changed
mysql> show tables;
+-----+
| Tables_in_problematic_upgrade |
+-----+
| recreated_table                |
+-----+
1 row in set (0.00 sec)
```

Post-upgrade cleanup for Aurora MySQL version 3

After you finish upgrading any Aurora MySQL version 1 or 2 clusters to Aurora MySQL version 3, you can perform these other cleanup actions:

- Create new MySQL 8.0-compatible versions of any custom parameter groups. Apply any necessary custom parameter values to the new parameter groups.
- Update any CloudWatch alarms, setup scripts, and so on to use the new names for any metrics whose names were affected by inclusive language changes. For a list of such metrics, see [Inclusive language changes for Aurora MySQL version 3 \(p. 751\)](#).
- Update any AWS CloudFormation templates to use the new names for any configuration parameters whose names were affected by inclusive language changes. For a list of such parameters, see [Inclusive language changes for Aurora MySQL version 3 \(p. 751\)](#).

Spatial indexes

After upgrading to Aurora MySQL version 3, check if you need to drop or recreate objects and indexes related to spatial indexes. Before MySQL 8.0, Aurora could optimize spatial queries using indexes that didn't contain a spatial resource identifier (SRID). Aurora MySQL version 3 only uses spatial indexes containing SRIDs. During an upgrade, Aurora automatically drops any spatial indexes without SRIDs and prints warning messages in the database log. If you observe such warning messages, create new spatial indexes with SRIDs after the upgrade. For more information about changes to spatial functions and data types in MySQL 8.0, see [Changes in MySQL 8.0](#) in the *MySQL Reference Manual*.

Aurora MySQL version 2 compatible with MySQL 5.7

The following features are supported in MySQL 5.7.12 but are currently not supported in Aurora MySQL 5.7:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The `CREATE TABLESPACE` SQL statement
- X Protocol

For more information about these features, see the [MySQL 5.7 documentation](#).

Comparison of Aurora MySQL 5.6 and Aurora MySQL 5.7

The following Amazon Aurora MySQL features are supported in Aurora MySQL 5.6, but these features are currently not supported in Aurora MySQL 5.7.

- Asynchronous key prefetch (AKP). For more information, see [Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch \(p. 1036\)](#).
- Hash joins. For more information, see [Optimizing large Aurora MySQL join queries with hash joins \(p. 1038\)](#).
- Native functions for synchronously invoking AWS Lambda functions. You can asynchronously invoke AWS Lambda functions from Aurora MySQL 5.7. For more information, see [Invoking a Lambda function with an Aurora MySQL native function \(p. 1012\)](#).
- Scan batching. For more information, see [Aurora MySQL database engine updates 2017-12-11 \(p. 1225\)](#).

Currently, Aurora MySQL 5.7 does not support features added in Aurora MySQL version 1.16 and later. For information about Aurora MySQL version 1.16, see [Aurora MySQL database engine updates 2017-12-11 \(p. 1225\)](#).

The performance schema isn't available for early releases of Aurora MySQL 5.7. Upgrade to Aurora 2.03 or higher for performance schema support.

Security with Amazon Aurora MySQL

Security for Amazon Aurora MySQL is managed at three levels:

- To control who can perform Amazon RDS management actions on Aurora MySQL DB clusters and DB instances, you use AWS Identity and Access Management (IAM). When you connect to AWS using IAM credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see [Identity and access management in Amazon Aurora \(p. 1724\)](#).

If you are using IAM to access the Amazon RDS console, you must first sign on to the AWS Management Console with your IAM user credentials. Then go to the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

- Aurora MySQL DB clusters must be created in an Amazon Virtual Private Cloud (VPC). To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora MySQL DB clusters in a VPC, you use a VPC security group. These endpoint and port connections can be made using Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see [Amazon Virtual Private Cloud VPCs and Amazon Aurora \(p. 1787\)](#).

The supported VPC tenancy depends on the DB instance class used by your Aurora MySQL DB clusters. With default VPC tenancy, the VPC runs on shared hardware. With dedicated VPC tenancy, the VPC runs on a dedicated hardware instance. The burstable performance DB instance classes support default VPC tenancy only. The burstable performance DB instance classes include the db.t2, db.t3, and db.t4g DB instance classes. All other Aurora MySQL DB instance classes support both default and dedicated VPC tenancy.

For more information about instance classes, see [Aurora DB instance classes \(p. 54\)](#). For more information about default and dedicated VPC tenancy, see [Dedicated instances](#) in the [Amazon Elastic Compute Cloud User Guide](#).

- To authenticate login and permissions for an Amazon Aurora MySQL DB cluster, you can take either of the following approaches, or a combination of them:
 - You can take the same approach as with a standalone instance of MySQL.

Commands such as `CREATE USER`, `RENAME USER`, `GRANT`, `REVOKE`, and `SET PASSWORD` work just as they do in on-premises databases, as does directly modifying database schema tables. For more information, see [Access control and account management](#) in the MySQL documentation.

- You can also use IAM database authentication.

With IAM database authentication, you authenticate to your DB cluster by using an IAM user or IAM role and an authentication token. An *authentication token* is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see [IAM database authentication \(p. 1743\)](#).

Note

For more information, see [Security in Amazon Aurora \(p. 1706\)](#).

Master user privileges with Amazon Aurora MySQL

When you create an Amazon Aurora MySQL DB instance, the master user has the following default privileges:

- ALTER
- ALTER ROUTINE
- CREATE
- CREATE ROUTINE
- CREATE TEMPORARY TABLES
- CREATE USER
- CREATE VIEW
- DELETE
- DROP
- EVENT
- EXECUTE
- GRANT OPTION
- INDEX
- INSERT
- LOAD FROM S3
- LOCK TABLES
- PROCESS
- REFERENCES
- RELOAD
- REPLICATION CLIENT
- REPLICATION SLAVE
- SELECT
- SHOW DATABASES
- SHOW VIEW
- TRIGGER
- UPDATE

To provide management services for each DB cluster, the `rdsadmin` user is created when the DB cluster is created. Attempting to drop, rename, change the password, or change privileges for the `rdsadmin` account results in an error.

For management of the Aurora MySQL DB cluster, the standard `kill` and `kill_query` commands have been restricted. Instead, use the Amazon RDS commands `rds_kill` and `rds_kill_query` to terminate user sessions or queries on Aurora MySQL DB instances.

Note

Encryption of a database instance and snapshots is not supported for the China (Ningxia) region.

Using SSL/TLS with Aurora MySQL DB clusters

Amazon Aurora MySQL DB clusters support Secure Sockets Layer (SSL) and Transport Layer Security (TLS) connections from applications using the same process and public key as RDS for MySQL DB instances.

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS

certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks. As a result, you can only use the DB cluster endpoint to connect to a DB cluster using SSL/TLS if your client supports Subject Alternative Names (SAN). Otherwise, you must use the instance endpoint of a writer instance.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1714\)](#).

We recommend the MariaDB Connector/J client as a client that supports SAN with SSL. For more information, see the [MariaDB Connector/J download](#) page.

Topics

- [Requiring an SSL/TLS connection to an Aurora MySQL DB cluster \(p. 776\)](#)
- [TLS versions for Aurora MySQL \(p. 776\)](#)
- [Encrypting connections to an Aurora MySQL DB cluster \(p. 777\)](#)

Requiring an SSL/TLS connection to an Aurora MySQL DB cluster

You can require that all user connections to your Aurora MySQL DB cluster use SSL/TLS by using the `require_secure_transport` DB cluster parameter. By default, the `require_secure_transport` parameter is set to OFF. You can set the `require_secure_transport` parameter to ON to require SSL/TLS for connections to your DB cluster.

You can set the `require_secure_transport` parameter value by updating the DB cluster parameter group for your DB cluster. You don't need to reboot your DB cluster for the change to take effect. For more information on parameter groups, see [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#).

Note

The `require_secure_transport` parameter is only available for Aurora MySQL version 5.7. You can set this parameter in a custom DB cluster parameter group. The parameter isn't available in DB instance parameter groups.

When the `require_secure_transport` parameter is set to ON for a DB cluster, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
MySQL Error 3159 (HY000): Connections using insecure transport are prohibited while --require_secure_transport=ON.
```

TLS versions for Aurora MySQL

Aurora MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, and 1.2. The following table shows the TLS support for Aurora MySQL versions.

Aurora MySQL version	TLS 1.0	TLS 1.1	TLS 1.2
Aurora MySQL version 3	Supported	Supported	Supported
Aurora MySQL version 2	Supported	Supported	Supported
Aurora MySQL version 1	Supported	Supported for Aurora MySQL 1.23.1 and higher	Supported for Aurora MySQL 1.23.1 and higher

Although the community edition of MySQL 8.0 supports TLS 1.3, the MySQL 8.0-compatible Aurora MySQL version 3 currently doesn't support TLS 1.3.

For an Aurora MySQL 5.7 DB cluster, you can use the `tls_version` DB cluster parameter to indicate the permitted protocol versions. Similar client parameters exist for most client tools or database drivers. Some older clients might not support newer TLS versions. By default, the DB cluster attempts to use the highest TLS protocol version allowed by both the server and client configuration.

Set the `tls_version` DB cluster parameter to one of the following values:

- `TLSv1.2` – Only the TLS version 1.2 protocol is permitted for encrypted connections.
- `TLSv1.1` – TLS version 1.1 and 1.2 protocols are permitted for encrypted connections.
- `TLSv1` – TLS version 1.0, 1.1, and 1.2 protocols are permitted for encrypted connections.

If the parameter isn't set, then TLS version 1.0, 1.1, and 1.2 protocols are permitted for encrypted connections.

For information about modifying parameters in a DB cluster parameter group, see [Modifying parameters in a DB cluster parameter group \(p. 349\)](#). If you use the AWS CLI to modify the `tls_version` DB cluster parameter, the `ApplyMethod` must be set to `pending-reboot`. When the application method is `pending-reboot`, changes to parameters are applied after you stop and restart the DB clusters associated with the parameter group.

Note

The `tls_version` DB cluster parameter isn't available for Aurora MySQL 5.6.

Encrypting connections to an Aurora MySQL DB cluster

To encrypt connections using the default `mysql` client, launch the `mysql` client using the `--ssl-ca` parameter to reference the public key, for example:

For MySQL 5.7 and 8.0:

```
mysql -h myinstance.123456789012.rds-us-east-1.amazonaws.com  
--ssl-ca=full_path_to_CA_certificate --ssl-mode=VERIFY_IDENTITY
```

For MySQL 5.6:

```
mysql -h myinstance.123456789012.rds-us-east-1.amazonaws.com  
--ssl-ca=full_path_to_CA_certificate --ssl-verify-server-cert
```

Replace `full_path_to_CA_certificate` with the full path to your Certificate Authority (CA) certificate. For information about downloading a certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1714\)](#).

You can require SSL/TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MySQL version, to require SSL/TLS connections on the user account `encrypted_user`.

For MySQL 5.7 and 8.0:

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For MySQL 5.6:

```
GRANT USAGE ON *.* TO 'encrypted_user'@'%' REQUIRE SSL;
```

When you use an RDS proxy, you connect to the proxy endpoint instead of the usual cluster endpoint. You can make SSL/TLS required or optional for connections to the proxy, in the same way as for connections directly to the Aurora DB cluster. For information about using the RDS Proxy, see [Using Amazon RDS Proxy \(p. 288\)](#).

Note

For more information on SSL/TLS connections with MySQL, see the [MySQL documentation](#).

Updating applications to connect to Aurora MySQL DB clusters using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your Aurora DB clusters using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB clusters. If they do, you can further check whether those applications require certificate verification to connect.

Note

Some applications are configured to connect to Aurora MySQL DB clusters only if they can successfully verify the certificate on the server.

For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB clusters. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate \(p. 1715\)](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1714\)](#). For information about using SSL/TLS with Aurora MySQL DB clusters, see [Using SSL/TLS with Aurora MySQL DB clusters \(p. 775\)](#).

Topics

- [Determining whether any applications are connecting to your Aurora MySQL DB cluster using SSL \(p. 778\)](#)
- [Determining whether a client requires certificate verification to connect \(p. 779\)](#)
- [Updating your application trust store \(p. 780\)](#)
- [Example Java code for establishing SSL connections \(p. 781\)](#)

Determining whether any applications are connecting to your Aurora MySQL DB cluster using SSL

If you are using Aurora MySQL version 2 (compatible with MySQL 5.7) and the Performance Schema is enabled, run the following query to check if connections are using SSL/TLS. For information about enabling the Performance Schema, see [Performance Schema quick start](#) in the MySQL documentation.

```
mysql> SELECT id, user, host, connection_type
```

```
FROM performance_schema.threads pst
INNER JOIN information_schema.processlist isp
ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (`admin`) and an application logged in as `webapp1` are using SSL.

```
+----+-----+-----+-----+
| id | user           | host          | connection_type |
+----+-----+-----+-----+
|  8 | admin          | 10.0.4.249:42590 | SSL/TLS        |
|  4 | event_scheduler | localhost      | NULL          |
| 10 | webapp1        | 159.28.1.1:42189 | SSL/TLS        |
+----+-----+-----+-----+
3 rows in set (0.00 sec)
```

If you are using Aurora MySQL version 1 (compatible with MySQL 5.6), then you can't determine from the server side whether applications are connecting with or without SSL. For those versions, you can determine whether SSL is used by examining the application's connection method. You can find more information on examining the client connection configuration in the following section.

Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see [Configuration properties](#) in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

MySQL

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see [Client-side configuration for encrypted connections](#) in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the --ssl-mode option you specify VERIFY_CA or VERIFY_IDENTITY, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the --ssl-verify-server-cert option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --ssl-verify-server-cert
```

Updating your application trust store

For information about updating the trust store for MySQL applications, see [Installing SSL certificates](#) in the MySQL documentation.

Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

To update the trust store for JDBC applications

1. Download the 2019 root certificate that works for all AWS Regions and put the file in the trust store directory.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster \(p. 1714\)](#).

2. Convert the certificate to .der format using the following command.

```
openssl x509 -outform der -in rds-ca-2019-root.pem -out rds-ca-2019-root.der
```

Replace the file name with the one that you downloaded.

3. Import the certificate into the key store using the following command.

```
keytool -import -alias rds-root -keystore clientkeystore -file rds-ca-2019-root.der
```

4. Confirm that the key store was updated successfully.

```
keytool -list -v -keystore clientkeystore.jks
```

Enter the metastore password when you are prompted for it.

Your output should contain the following.

```
rds-root, date, trustedCertEntry,  
Certificate fingerprint (SHA1):  
D4:0D:DB:29:E3:75:0D:FF:A6:71:C3:14:0B:BF:5F:47:8D:1C:80:96  
# This fingerprint should match the output from the below command  
openssl x509 -fingerprint -in rds-ca-2019-root.pem -noout
```

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -
Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```
public class MySQLSSLTest {

    private static final String DB_USER = "user name";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void test(String[] args) throws Exception {
        Class.forName("com.mysql.jdbc.Driver");

        System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

        Properties properties = new Properties();
        properties.setProperty("sslMode", "VERIFY_IDENTITY");
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);

        Connection connection = DriverManager.getConnection("jdbc:mysql://jagdeeps-ssl-
test.cni62e2e7kwh.us-east-1.rds.amazonaws.com:3306", properties);
        Statement stmt=connection.createStatement();

        ResultSet rs=stmt.executeQuery("SELECT 1 from dual");

        return;
    }
}
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance \(p. 1716\)](#).

Migrating data to an Amazon Aurora MySQL DB cluster

You have several options for migrating data from your existing database to an Amazon Aurora MySQL DB cluster. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating.

There are two different types of migration: physical and logical. Physical migration means that physical copies of database files are used to migrate the database. Logical migration means that the migration is accomplished by applying logical database changes, such as inserts, updates, and deletes.

Physical migration has the following advantages:

- Physical migration is faster than logical migration, especially for large databases.
- Database performance does not suffer when a backup is taken for physical migration.
- Physical migration can migrate everything in the source database, including complex database components.

Physical migration has the following limitations:

- The `innodb_page_size` parameter must be set to its default value (16KB).
- The `innodb_data_file_path` parameter must be configured with only one data file that uses the default data file name "ibdata1:12M:autoextend". Databases with two data files, or with a data file with a different name, can't be migrated using this method.

The following are examples of file names that are not allowed:

"`innodb_data_file_path=ibdata1:50M; ibdata2:50M:autoextend`" and
"`innodb_data_file_path=ibdata01:50M:autoextend`".

- The `innodb_log_files_in_group` parameter must be set to its default value (2).

Logical migration has the following advantages:

- You can migrate subsets of the database, such as specific tables or parts of a table.
- The data can be migrated regardless of the physical storage structure.

Logical migration has the following limitations:

- Logical migration is usually slower than physical migration.
- Complex database components can slow down the logical migration process. In some cases, complex database components can even block logical migration.

The following table describes your options and the type of migration for each option.

Migrating from	Migration type	Solution
An RDS for MySQL DB instance	Physical	You can migrate from an RDS for MySQL DB instance by first creating an Aurora MySQL read replica of a MySQL DB instance. When the replica lag between the MySQL DB instance and the Aurora MySQL read replica is 0, you can direct your client applications to read from the Aurora read replica and then stop replication to make the Aurora MySQL read replica a standalone Aurora MySQL DB cluster for reading and writing. For details, see Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica (p. 803) .

Migrating from	Migration type	Solution
An RDS for MySQL DB snapshot	Physical	You can migrate data directly from an RDS for MySQL DB snapshot to an Amazon Aurora MySQL DB cluster. For details, see Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using a DB snapshot (p. 797) .
A MySQL database external to Amazon RDS	Logical	You can create a dump of your data using the <code>mysqldump</code> utility, and then import that data into an existing Amazon Aurora MySQL DB cluster. For details, see Migrating from MySQL to Amazon Aurora by using mysqldump (p. 796) .
A MySQL database external to Amazon RDS	Physical	You can copy the backup files from your database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora MySQL DB cluster from those files. This option can be considerably faster than migrating data using <code>mysqldump</code> . For details, see Migrating data from MySQL by using an Amazon S3 bucket (p. 784) .
A MySQL database external to Amazon RDS	Logical	You can save data from your database as text files and copy those files to an Amazon S3 bucket. You can then load that data into an existing Aurora MySQL DB cluster using the <code>LOAD DATA FROM S3</code> MySQL command. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 997) .
A database that is not MySQL-compatible	Logical	You can use AWS Database Migration Service (AWS DMS) to migrate data from a database that is not MySQL-compatible. For more information on AWS DMS, see What is AWS database migration service?

Note

- If you are migrating a MySQL database external to Amazon RDS, the migration options described in the table are supported only if your database supports the InnoDB or MyISAM tablespaces.
- If the MySQL database you are migrating to Aurora MySQL uses memcached, remove memcached before migrating it.

Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster

If your database supports the InnoDB or MyISAM tablespaces, you have these options for migrating your data to an Amazon Aurora MySQL DB cluster:

- You can create a dump of your data using the `mysqldump` utility, and then import that data into an existing Amazon Aurora MySQL DB cluster. For more information, see [Migrating from MySQL to Amazon Aurora by using mysqldump \(p. 796\)](#).
- You can copy the full and incremental backup files from your database to an Amazon S3 bucket, and then restore an Amazon Aurora MySQL DB cluster from those files. This option can be considerably faster than migrating data using `mysqldump`. For more information, see [Migrating data from MySQL by using an Amazon S3 bucket \(p. 784\)](#).

Migrating data from MySQL by using an Amazon S3 bucket

You can copy the full and incremental backup files from your source MySQL version 5.5, 5.6, or 5.7 database to an Amazon S3 bucket, and then restore an Amazon Aurora MySQL DB cluster from those files.

This option can be considerably faster than migrating data using `mysqldump`, because using `mysqldump` replays all of the commands to recreate the schema and data from your source database in your new Aurora MySQL DB cluster. By copying your source MySQL data files, Aurora MySQL can immediately use those files as the data for an Aurora MySQL DB cluster.

Note

The Amazon S3 bucket and the Amazon Aurora MySQL DB cluster must be in the same AWS Region.

Aurora MySQL doesn't restore everything from your database. You should save the database schema and values for the following items from your source MySQL database and add them to your restored Aurora MySQL DB cluster after it has been created:

- User accounts
- Functions
- Stored procedures
- Time zone information. Time zone information is loaded from the local operating system of your Amazon Aurora MySQL DB cluster. For more information, see [Local time zone for Amazon Aurora DB clusters \(p. 16\)](#).

You can't restore from an encrypted source database, but you can encrypt the data being migrated. You can also leave the data unencrypted during the migration process.

You can't migrate from a source database that has tables defined outside of the default MySQL data directory.

Also, decide whether you want to minimize downtime by using binary log replication during the migration process. If you use binary log replication, the external MySQL database remains open to transactions while the data is being migrated to the Aurora MySQL DB cluster. After the Aurora MySQL DB cluster has been created, you use binary log replication to synchronize the Aurora MySQL DB cluster with the transactions that happened after the backup. When the Aurora MySQL DB cluster is caught up with the MySQL database, you finish the migration by completely switching to the Aurora MySQL DB cluster for new transactions.

Topics

- [Before you begin \(p. 785\)](#)
- [Backing up files to be restored as an Amazon Aurora MySQL DB cluster \(p. 786\)](#)
- [Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket \(p. 788\)](#)
- [Synchronizing the Amazon Aurora MySQL DB cluster with the MySQL database using replication \(p. 791\)](#)

Before you begin

Before you can copy your data to an Amazon S3 bucket and restore a DB cluster from those files, you must do the following:

- Install Percona XtraBackup on your local server.
- Permit Aurora MySQL to access your Amazon S3 bucket on your behalf.

Installing Percona XtraBackup

Amazon Aurora can restore a DB cluster from files that were created using Percona XtraBackup. You can install Percona XtraBackup from [Download Percona XtraBackup](#).

Note

For MySQL 5.7 migration, you must use Percona XtraBackup 2.4. For earlier MySQL versions, use Percona XtraBackup 2.3 or 2.4.

Required permissions

To migrate your MySQL data to an Amazon Aurora MySQL DB cluster, several permissions are required:

- The user that is requesting that Aurora create a new cluster from an Amazon S3 bucket must have permission to list the buckets for your AWS account. You grant the user this permission using an AWS Identity and Access Management (IAM) policy.
- Aurora requires permission to act on your behalf to access the Amazon S3 bucket where you store the files used to create your Amazon Aurora MySQL DB cluster. You grant Aurora the required permissions using an IAM service role.
- The user making the request must also have permission to list the IAM roles for your AWS account.
- If the user making the request is to create the IAM service role or request that Aurora create the IAM service role (by using the console), then the user must have permission to create an IAM role for your AWS account.
- If you plan to encrypt the data during the migration process, update the IAM policy of the user who will perform the migration to grant RDS access to the AWS KMS keys used for encrypting the backups. For instructions, see [Creating an IAM policy to access AWS KMS resources \(p. 990\)](#).

For example, the following IAM policy grants a user the minimum required permissions to use the console to list IAM roles, create an IAM role, list the Amazon S3 buckets for your account, and list the KMS keys.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "iam>ListRoles",  
                "iam>CreateRole",  
                "iam>CreatePolicy",  
                "s3>ListBuckets",  
                "kms>ListKeys"  
            ]  
        }  
    ]  
}
```

```
        "iam:AttachRolePolicy",
        "s3>ListBucket",
        "kms>ListKeys"
    ],
    "Resource": "*"
}
]
```

Additionally, for a user to associate an IAM role with an Amazon S3 bucket, the IAM user must have the `iam:PassRole` permission for that IAM role. This permission allows an administrator to restrict which IAM roles a user can associate with Amazon S3 buckets.

For example, the following IAM policy allows a user to associate the role named `S3Access` with an Amazon S3 bucket.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowS3AccessRole",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::123456789012:role/S3Access"
        }
    ]
}
```

For more information on IAM user permissions, see [Managing access using policies \(p. 1726\)](#).

Creating the IAM service role

You can have the AWS Management Console create a role for you by choosing the **Create a New Role** option (shown later in this topic). If you select this option and specify a name for the new role, then Aurora creates the IAM service role required for Aurora to access your Amazon S3 bucket with the name that you supply.

As an alternative, you can manually create the role using the following procedure.

To create an IAM role for Aurora to access Amazon S3

1. Complete the steps in [Creating an IAM policy to access Amazon S3 resources \(p. 986\)](#).
2. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access AWS services \(p. 991\)](#).
3. Complete the steps in [Associating an IAM role with an Amazon Aurora MySQL DB cluster \(p. 992\)](#).

Backing up files to be restored as an Amazon Aurora MySQL DB cluster

You can create a full backup of your MySQL database files using Percona XtraBackup and upload the backup files to an Amazon S3 bucket. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files to an Amazon S3 bucket.

Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that can be restored from Amazon S3 to create an Amazon Aurora MySQL DB cluster, use the Percona XtraBackup utility (`xtrabackup`) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the /on-premises/s3-restore/backup folder.

```
xtrabackup --backup --user=<myuser> --password=<password> --target-dir=</on-premises/s3-restore/backup>
```

If you want to compress your backup into a single file (which can be split, if needed), you can use the --stream option to save your backup in one of the following formats:

- Gzip (.gz)
- tar (.tar)
- Percona xbstream (.xbstream)

The following command creates a backup of your MySQL database split into multiple Gzip files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \  
--target-dir=</on-premises/s3-restore/backup> | gzip - | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.tar.gz
```

The following command creates a backup of your MySQL database split into multiple tar files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \  
--target-dir=</on-premises/s3-restore/backup> | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.tar
```

The following command creates a backup of your MySQL database split into multiple xbstream files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=xbstream \  
--target-dir=</on-premises/s3-restore/backup> | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.xbstream
```

Once you have backed up your MySQL database using the Percona XtraBackup utility, you can copy your backup directories and files to an Amazon S3 bucket.

For information on creating and uploading a file to an Amazon S3 bucket, see [Getting started with Amazon Simple Storage Service](#) in the [Amazon S3 Getting Started Guide](#).

Using incremental backups with Percona XtraBackup

Amazon Aurora MySQL supports both full and incremental backups created using Percona XtraBackup. If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files for your full and incremental backups to an Amazon S3 bucket. For more information about creating incremental backups using Percona XtraBackup, see [Incremental backup](#).

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Aurora iterates through all files and directories. Aurora uses the `xtrabackup-checkpoints` file included with each incremental backup to identify the base directory and to order incremental backups by log sequence number (LSN) range.

For information on creating and uploading a file to an Amazon S3 bucket, see [Getting started with Amazon Simple Storage Service](#) in the [Amazon S3 Getting Started Guide](#).

Backup considerations

When you upload a file to an Amazon S3 bucket, you can use server-side encryption to encrypt the data. You can then restore an Amazon Aurora MySQL DB cluster from those encrypted files. Amazon Aurora MySQL can restore a DB cluster with files encrypted using the following types of server-side encryption:

- Server-side encryption with Amazon S3-managed keys (SSE-S3) – Each object is encrypted with a unique key employing strong multifactor encryption.
- Server-side encryption with AWS KMS-managed keys (SSE-KMS) – Similar to SSE-S3, but you have the option to create and manage encryption keys yourself, and also other differences.

For information about using server-side encryption when uploading files to an Amazon S3 bucket, see [Protecting data using server-side encryption](#) in the *Amazon S3 Developer Guide*.

Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If the backup data for your database exceeds 5 TB, use the `split` command to split the backup files into multiple files that are each less than 5 TB.

Aurora limits the number of source files uploaded to an Amazon S3 bucket to 1 million files. In some cases, backup data for your database, including all full and incremental backups, can come to a large number of files. In these cases, use a tarball (.tar.gz) file to store full and incremental backup files in the Amazon S3 bucket.

Aurora consumes your backup files based on the file name. Be sure to name your backup files with the appropriate file extension based on the file format—for example, `.xbstream` for files stored using the Percona xbstream format.

Aurora consumes your backup files in alphabetical order and also in natural number order. Always use the `split` option when you issue the `xtrabackup` command to ensure that your backup files are written and named in the proper order.

Aurora doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database: `--tables`, `--tables-exclude`, `--tables-file`, `--databases`, `--databases-exclude`, or `--databases-file`.

For more information about backing up your database with Percona XtraBackup, see [Percona XtraBackup - documentation](#) and [The xtrabackup binary](#) on the Percona website.

Aurora supports incremental backups created using Percona XtraBackup. For more information about creating incremental backups using Percona XtraBackup, see [Incremental backup](#).

Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket

You can restore your backup files from your Amazon S3 bucket to create a new Amazon Aurora MySQL DB cluster by using the Amazon RDS console.

To restore an Amazon Aurora MySQL DB cluster from files on an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the top right corner of the Amazon RDS console, choose the AWS Region in which to create your DB cluster. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose **Databases**, and then choose **Restore from S3**.
4. Choose **Restore from S3**.

The **Create database by restoring from S3** page appears.

Create database by restoring from S3

S3 destination

Write audit logs to S3

Enter a destination in Amazon S3 where your audit logs will be stored. Amazon S3 is object storage build to store and retrieve any amount of data from anywhere

test-eu1-bucket

S3 prefix (optional) [Info](#)

Engine options

Engine type [Info](#)

Amazon Aurora

MySQL

Edition

Amazon Aurora with MySQL compatibility

Version [Info](#)

Aurora (MySQL 5.7) 2.07.2

IAM role

IAM role

Choose or create an IAM role to grant write access to your S3 bucket.

Choose an option

Settings

DB cluster identifier [Info](#)

Type a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

database-1

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

[▼ Credentials Settings](#)

789

Master username [Info](#)

Type a login ID for the master user of your DB instance.

admin

5. Under **S3 destination**:

- a. Choose the **S3 bucket** that contains the backup files.
- b. (Optional) For **S3 folder path prefix**, enter a file path prefix for the files stored in your Amazon S3 bucket.

If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

For example, suppose that you store your backup files on S3 in a subfolder named backups, and you have multiple sets of backup files, each in its own directory (gzip_backup1, gzip_backup2, and so on). In this case, you specify a prefix of backups/gzip_backup1 to restore from the files in the gzip_backup1 folder.

6. Under **Engine options**:

- a. For **Engine type**, choose **Amazon Aurora**.
 - b. For **Version**, choose the Aurora MySQL engine version for your restored DB instance.
7. For **IAM role**, you can choose an existing IAM role.
8. (Optional) You can also have a new IAM role created for you by choosing **Create a new role**. If so:

- a. Enter the **IAM role name**.
- b. Choose whether to **Allow access to KMS key**:
 - If you didn't encrypt the backup files, choose **No**.
 - If you encrypted the backup files with AES-256 (SSE-S3) when you uploaded them to Amazon S3, choose **No**. In this case, the data is decrypted automatically.
 - If you encrypted the backup files with AWS KMS (SSE-KMS) server-side encryption when you uploaded them to Amazon S3, choose **Yes**. Next, choose the correct KMS key for **AWS KMS key**.

The AWS Management Console creates an IAM policy that enables Aurora to decrypt the data.

For more information, see [Protecting data using server-side encryption](#) in the *Amazon S3 Developer Guide*.

9. Choose settings for your DB cluster, such as the DB cluster identifier and the login credentials. For information about each setting, see [Settings for Aurora DB clusters \(p. 137\)](#).
10. Customize additional settings for your Aurora MySQL DB cluster as needed.
11. Choose **Create database** to launch your Aurora DB instance.

On the Amazon RDS console, the new DB instance appears in the list of DB instances. The DB instance has a status of **creating** until the DB instance is created and ready for use. When the state changes to **available**, you can connect to the primary instance for your DB cluster. Depending on the DB instance class and store allocated, it can take several minutes for the new instance to be available.

To view the newly created cluster, choose the **Databases** view in the Amazon RDS console and choose the DB cluster. For more information, see [Viewing an Amazon Aurora DB cluster \(p. 547\)](#).

The screenshot shows the AWS RDS console for a database named 'database-1'. The 'Connectivity & security' tab is active. It lists two endpoints:

Endpoint name	Status
database-1.cluster-ro-... .us-east-2.rds.amazonaws.com	Available
database-1.cluster-... .us-east-2.rds.amazonaws.com	Available

Note the port and the writer endpoint of the DB cluster. Use the writer endpoint and port of the DB cluster in your JDBC and ODBC connection strings for any application that performs write or read operations.

Synchronizing the Amazon Aurora MySQL DB cluster with the MySQL database using replication

To achieve little or no downtime during the migration, you can replicate transactions that were committed on your MySQL database to your Aurora MySQL DB cluster. Replication enables the DB cluster to catch up with the transactions on the MySQL database that happened during the migration. When the DB cluster is completely caught up, you can stop the replication and finish the migration to Aurora MySQL.

Topics

- [Configuring your external MySQL database and your Aurora MySQL DB cluster for encrypted replication \(p. 792\)](#)
- [Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database \(p. 793\)](#)

Configuring your external MySQL database and your Aurora MySQL DB cluster for encrypted replication

To replicate data securely, you can use encrypted replication.

Note

If you don't need to use encrypted replication, you can skip these steps and move on to the instructions in [Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database \(p. 793\)](#).

The following are prerequisites for using encrypted replication:

- Secure Sockets Layer (SSL) must be enabled on the external MySQL primary database.
- A client key and client certificate must be prepared for the Aurora MySQL DB cluster.

During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

To configure your external MySQL database and your Aurora MySQL DB cluster for encrypted replication

1. Ensure that you are prepared for encrypted replication:
 - If you don't have SSL enabled on the external MySQL primary database and don't have a client key and client certificate prepared, enable SSL on the MySQL database server and generate the required client key and client certificate.
 - If SSL is enabled on the external primary, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key that you used to configure SSL on the external MySQL primary database.

For more information, see [Creating SSL certificates and keys using openssl](#) in the MySQL documentation.

You need the certificate authority certificate, the client key, and the client certificate.

2. Connect to the Aurora MySQL DB cluster as the primary user using SSL.

For information about connecting to an Aurora MySQL DB cluster with SSL, see [Using SSL/TLS with Aurora MySQL DB clusters \(p. 775\)](#).

3. Run the `mysql.rds_import_binlog_ssl_material` stored procedure to import the SSL information into the Aurora MySQL DB cluster.

For the `ssl_material_value` parameter, insert the information from the .pem format files for the Aurora MySQL DB cluster in the correct JSON payload.

The following example imports SSL information into an Aurora MySQL DB cluster. In .pem format files, the body code typically is longer than the body code shown in the example.

```
call mysql.rds_import_binlog_ssl_material(
  '{"ssl_ca": "-----BEGIN CERTIFICATE-----"
```

```
AAAAAB3NzaC1yc2EAAAQABAAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS706V

BQoQzd8v7yeb70z1PnWoyN0qFU0XA246RA8QFYiCNYwI3f05p6KLxEXAMPLE
-----END RSA PRIVATE KEY-----\n"}');
```

For more information, see [mysql_rds_import_binlog_ssl_material Using SSL/TLS with Aurora MySQL DB clusters \(p. 775\)](#).

Note

After running the procedure, the secrets are stored in files. To erase the files later, you can run the [mysql_rds_remove_binlog_ssl_material](#) stored procedure.

Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database

You can synchronize your Amazon Aurora MySQL DB cluster with the MySQL database using replication.

To synchronize your Aurora MySQL DB cluster with the MySQL database using replication

1. Ensure that the /etc/my.cnf file for the external MySQL database has the relevant entries.

If encrypted replication is not required, ensure that the external MySQL database is started with binary logs (binlogs) enabled and SSL disabled. The following are the relevant entries in the /etc/my.cnf file for unencrypted data.

```
log-bin=mysql-bin
server-id=2133421
innodb_flush_log_at_trx_commit=1
sync_binlog=1
```

If encrypted replication is required, ensure that the external MySQL database is started with SSL and binlogs enabled. The entries in the /etc/my.cnf file include the .pem file locations for the MySQL database server.

```
log-bin=mysql-bin
server-id=2133421
innodb_flush_log_at_trx_commit=1
sync_binlog=1

# Setup SSL.
ssl-ca=/home/sslcerts/ca.pem
ssl-cert=/home/sslcerts/server-cert.pem
ssl-key=/home/sslcerts/server-key.pem
```

You can verify that SSL is enabled with the following command.

```
mysql> show variables like 'have_ssl';
```

Your output should be similar the following.

```
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_ssl     | YES   |
+-----+-----+
1 row in set (0.00 sec)
```

2. Determine the starting binary log position for replication. You specify the position to start replication in a later step.

Using the AWS Management Console

- Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
- In the navigation pane, choose **Events**.
- In the **Events** list, note the position in the **Recovered from Binary log filename** event.

Events (3)		
Identifier	Type	Event
testingest	Instances	DB instance created
testingest	Instances	Binlog position from crash recovery is OFF.000001 532
testingest-cluster	DB clusters	Recovered from Binary log filename 'mysqld-bin.00001'

Using the AWS CLI

You can also get the binlog file name and position by calling the `describe-events` command from the AWS CLI. The following shows an example `describe-events` command.

```
PROMPT> aws rds describe-events
```

In the output, identify the event that shows the binlog position.

3. While connected to the external MySQL database, create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```
mysql> CREATE USER '<user_name>'@'<domain_name>' IDENTIFIED BY '<password>;'
```

The user requires the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges. Grant these privileges to the user.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO '<user_name>'@'<domain_name>';
```

If you need to use encrypted replication, require SSL connections for the replication user. For example, you can use the following statement to require SSL connections on the user account `<user_name>`.

```
GRANT USAGE ON *.* TO '<user_name>'@'<domain_name>' REQUIRE SSL;
```

Note

If `REQUIRE SSL` is not included, the replication connection might silently fall back to an unencrypted connection.

4. In the Amazon RDS console, add the IP address of the server that hosts the external MySQL database to the VPC security group for the Aurora MySQL DB cluster. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

You might also need to configure your local network to permit connections from the IP address of your Aurora MySQL DB cluster, so that it can communicate with your external MySQL database. To find the IP address of the Aurora MySQL DB cluster, use the `host` command.

```
host <db_cluster_endpoint>
```

The host name is the DNS name from the Aurora MySQL DB cluster endpoint.

5. Enable binary log replication by running the `mysql.rds_set_external_master` (Aurora MySQL version 1 and 2) or `mysql.rds_set_external_source` (Aurora MySQL version 3 and higher) stored procedure. This stored procedure has the following syntax.

```
CALL mysql.rds_set_external_master (
    host_name
    , host_port
    , replication_user_name
    , replication_user_password
    , mysql_binary_log_file_name
    , mysql_binary_log_file_location
    , ssl_encryption
);
CALL mysql.rds_set_external_source (
    host_name
    , host_port
    , replication_user_name
    , replication_user_password
    , mysql_binary_log_file_name
    , mysql_binary_log_file_location
    , ssl_encryption
);
```

For information about the parameters, see [mysql_rds_set_external_master](#).

For `mysql_binary_log_file_name` and `mysql_binary_log_file_location`, use the position in the **Recovered from Binary log filename** event you noted earlier.

If the data in the Aurora MySQL DB cluster is not encrypted, the `ssl_encryption` parameter must be set to 0. If the data is encrypted, the `ssl_encryption` parameter must be set to 1.

The following example runs the procedure for an Aurora MySQL DB cluster that has encrypted data.

```
CALL mysql.rds_set_external_master(
    'Externaldb.some.com',
    3306,
    'repl_user'@'mydomain.com',
    'password',
    'mysql-bin.000010',
    120,
    1);

CALL mysql.rds_set_external_source(
    'Externaldb.some.com',
    3306,
    'repl_user'@'mydomain.com',
    'password',
    'mysql-bin.000010',
    120,
    1);
```

This stored procedure sets the parameters that the Aurora MySQL DB cluster uses for connecting to the external MySQL database and reading its binary log. If the data is encrypted, it also downloads the SSL certificate authority certificate, client certificate, and client key to the local disk.

6. Start binary log replication by running the `mysql.rds_start_replication` stored procedure.

```
CALL mysql.rds_start_replication;
```

7. Monitor how far the Aurora MySQL DB cluster is behind the MySQL replication primary database. To do so, connect to the Aurora MySQL DB cluster and run the following command.

```
Aurora MySQL version 1 and 2:
SHOW SLAVE STATUS;

Aurora MySQL version 3:
SHOW REPLICA STATUS;
```

In the command output, the `Seconds_Behind_Master` field shows how far the Aurora MySQL DB cluster is behind the MySQL primary. When this value is 0 (zero), the Aurora MySQL DB cluster has caught up to the primary, and you can move on to the next step to stop replication.

8. Connect to the MySQL replication primary database and stop replication. To do so, run the following command.

```
CALL mysql.rds_stop_replication;
```

Migrating from MySQL to Amazon Aurora by using mysqldump

Because Amazon Aurora MySQL is a MySQL-compatible database, you can use the `mysqldump` utility to copy data from your MySQL or MariaDB database to an existing Aurora MySQL DB cluster.

For a discussion of how to do so with MySQL databases that are very large, see [Importing data to a MySQL or MariaDB DB instance with reduced downtime](#). For MySQL databases that have smaller amounts of data, see [Importing data from a MySQL or MariaDB DB to a MySQL or MariaDB DB instance](#).

Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using a DB snapshot

You can migrate (copy) data to an Amazon Aurora MySQL DB cluster from an RDS for MySQL DB snapshot, as described following.

Topics

- [Migrating an RDS for MySQL snapshot to Aurora \(p. 797\)](#)
- [Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica \(p. 803\)](#)

Note

Because Amazon Aurora MySQL is compatible with MySQL, you can migrate data from your MySQL database by setting up replication between your MySQL database and an Amazon Aurora MySQL DB cluster. If you want to use replication to migrate data from your MySQL database, we recommend that your MySQL database run MySQL version 5.5 or later. For more information, see [Replication with Amazon Aurora \(p. 70\)](#).

Migrating an RDS for MySQL snapshot to Aurora

You can migrate a DB snapshot of an RDS for MySQL DB instance to create an Aurora MySQL DB cluster. The new Aurora MySQL DB cluster is populated with the data from the original RDS for MySQL DB instance. The DB snapshot must have been made from an Amazon RDS DB instance running MySQL version 5.6 or 5.7.

You can migrate either a manual or automated DB snapshot. After the DB cluster is created, you can then create optional Aurora Replicas.

When the MySQL DB instance and the Aurora DB cluster are running the same version of MySQL, you can restore the MySQL snapshot directly to the Aurora DB cluster. For example, you can restore a MySQL version 5.6 snapshot directly to Aurora MySQL version 5.6, but you can't restore a MySQL version 5.6 snapshot directly to Aurora MySQL version 5.7.

If you want to migrate a MySQL version 5.6 snapshot to Aurora MySQL version 5.7, you can perform the migration in one of the following ways:

- Migrate the MySQL version 5.6 snapshot to Aurora MySQL version 5.6, take a snapshot of the Aurora MySQL version 5.6 DB cluster, and then restore the Aurora MySQL version 5.6 snapshot to Aurora MySQL version 5.7.
- Upgrade the MySQL version 5.6 snapshot to MySQL version 5.7, take a snapshot of the MySQL version 5.7 DB instance, and then restore the MySQL version 5.7 snapshot to Aurora MySQL version 5.7.

Note

You can also migrate a MySQL DB instance to an Aurora MySQL DB cluster by creating an Aurora read replica of your source MySQL DB instance. For more information, see [Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica \(p. 803\)](#).

You can't migrate a MySQL version 5.7 snapshot to Aurora MySQL version 5.6.

The general steps you must take are as follows:

1. Determine the amount of space to provision for your Aurora MySQL DB cluster. For more information, see [How much space do I need? \(p. 798\)](#)
2. Use the console to create the snapshot in the AWS Region where the Amazon RDS MySQL instance is located. For information about creating a DB snapshot, see [Creating a DB snapshot](#).
3. If the DB snapshot is not in the same AWS Region as your DB cluster, use the Amazon RDS console to copy the DB snapshot to that AWS Region. For information about copying a DB snapshot, see [Copying a DB snapshot](#).
4. Use the console to migrate the DB snapshot and create an Aurora MySQL DB cluster with the same databases as the original MySQL DB instance.

Warning

Amazon RDS limits each AWS account to one snapshot copy into each AWS Region at a time.

How much space do I need?

When you migrate a snapshot of a MySQL DB instance into an Aurora MySQL DB cluster, Aurora uses an Amazon Elastic Block Store (Amazon EBS) volume to format the data from the snapshot before migrating it. In some cases, additional space is needed to format the data for migration.

Tables that are not MyISAM tables and are not compressed can be up to 16 TB in size. If you have MyISAM tables, then Aurora must use additional space in the volume to convert the tables to be compatible with Aurora MySQL. If you have compressed tables, then Aurora must use additional space in the volume to expand these tables before storing them on the Aurora cluster volume. Because of this additional space requirement, you should ensure that none of the MyISAM and compressed tables being migrated from your MySQL DB instance exceeds 8 TB in size.

Reducing the amount of space required to migrate data into Amazon Aurora MySQL

You might want to modify your database schema prior to migrating it into Amazon Aurora. Such modification can be helpful in the following cases:

- You want to speed up the migration process.
- You are unsure of how much space you need to provision.
- You have attempted to migrate your data and the migration has failed due to a lack of provisioned space.

You can make the following changes to improve the process of migrating a database into Amazon Aurora.

Important

Be sure to perform these updates on a new DB instance restored from a snapshot of a production database, rather than on a production instance. You can then migrate the data from the snapshot of your new DB instance into your Aurora DB cluster to avoid any service interruptions on your production database.

Table type	Limitation or guideline
MyISAM tables	Aurora MySQL supports InnoDB tables only. If you have MyISAM tables in your database, then those tables must be converted before being migrated into Aurora MySQL. The conversion process requires additional space for the MyISAM to InnoDB conversion during the migration procedure.

Table type	Limitation or guideline
	<p>To reduce your chances of running out of space or to speed up the migration process, convert all of your MyISAM tables to InnoDB tables before migrating them. The size of the resulting InnoDB table is equivalent to the size required by Aurora MySQL for that table. To convert a MyISAM table to InnoDB, run the following command:</p> <pre style="margin-left: 40px;">alter table <schema>.〈table_name〉 engine=innodb, algorithm=copy;</pre>
Compressed tables	<p>Aurora MySQL doesn't support compressed tables (that is, tables created with <code>ROW_FORMAT=COMPRESSED</code>).</p> <p>To reduce your chances of running out of space or to speed up the migration process, expand your compressed tables by setting <code>ROW_FORMAT</code> to <code>DEFAULT</code>, <code>COMPACT</code>, <code>DYNAMIC</code>, or <code>REDUNDANT</code>. For more information, see https://dev.mysql.com/doc/refman/5.6/en/innodb-row-format.html.</p>

You can use the following SQL script on your existing MySQL DB instance to list the tables in your database that are MyISAM tables or compressed tables.

```
-- This script examines a MySQL database for conditions that block
-- migrating the database into Amazon Aurora.
-- It needs to be run from an account that has read permission for the
-- INFORMATION_SCHEMA database.

-- Verify that this is a supported version of MySQL.

select msg as `==> Checking current version of MySQL.`
from
(
select
    'This script should be run on MySQL version 5.6. ' +
    'Earlier versions are not supported.' as msg,
    cast(substring_index(version(), '.', 1) as unsigned) * 100 +
    cast(substring_index(substring_index(version(), '.', 2), '.', -1)
        as unsigned)
as major_minor
) as T
where major_minor <> 506;

-- List MyISAM and compressed tables. Include the table size.

select concat(TABLE_SCHEMA, '.', TABLE_NAME) as `==> MyISAM or Compressed Tables`,
round(((data_length + index_length) / 1024 / 1024), 2) "Approx size (MB)"
from INFORMATION_SCHEMA.TABLES
where
    ENGINE <> 'InnoDB'
and
(
    -- User tables
    TABLE_SCHEMA not in ('mysql', 'performance_schema',
                          'information_schema')
or
    -- Non-standard system tables
(
    TABLE_SCHEMA = 'mysql' and TABLE_NAME not in
    (
        'columns_priv', 'db', 'event', 'func', 'general_log',
        'procs_priv', 'tables_priv', 'time_zone_leap_second',
        'time_zone_name', 'time_zone_transition',
        'time_zone_transition_time'
    )
)
)
```

```
'help_category', 'help_keyword', 'help_relation',
'help_topic', 'host', 'ndb_binlog_index', 'plugin',
'proc', 'procs_priv', 'proxies_priv', 'servers', 'slow_log',
'tables_priv', 'time_zone', 'time_zone_leap_second',
'time_zone_name', 'time_zone_transition',
'time_zone_transition_type', 'user'
)
)
)
or
(
-- Compressed tables
ROW_FORMAT = 'Compressed'
);
```

The script produces output similar to the output in the following example. The example shows two tables that must be converted from MyISAM to InnoDB. The output also includes the approximate size of each table in megabytes (MB).

==> MyISAM or Compressed Tables	Approx size (MB)
test.name_table	2102.25
test.my_table	65.25

2 rows in set (0.01 sec)

Console

You can migrate a DB snapshot of an RDS for MySQL DB instance to create an Aurora MySQL DB cluster. The new Aurora MySQL DB cluster is populated with the data from the original RDS for MySQL DB instance. The DB snapshot must have been made from an Amazon RDS DB instance running MySQL version 5.6 or 5.7. For information about creating a DB snapshot, see [Creating a DB snapshot](#).

If the DB snapshot is not in the AWS Region where you want to locate your data, use the Amazon RDS console to copy the DB snapshot to that AWS Region. For information about copying a DB snapshot, see [Copying a DB snapshot](#).

When you migrate the DB snapshot by using the AWS Management Console, the console takes the actions necessary to create both the DB cluster and the primary instance.

You can also choose for your new Aurora MySQL DB cluster to be encrypted at rest using an AWS KMS key.

To migrate a MySQL DB snapshot by using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Either start the migration from the MySQL DB instance or from the snapshot:

To start the migration from the DB instance:

1. In the navigation pane, choose **Databases**, and then select the MySQL DB instance.
2. For **Actions**, choose **Migrate latest snapshot**.

To start the migration from the snapshot:

1. Choose **Snapshots**.

2. On the **Snapshots** page, choose the snapshot that you want to migrate into an Aurora MySQL DB cluster.
3. Choose **Snapshot Actions**, and then choose **Migrate Snapshot**.

The **Migrate Database** page appears.

3. Set the following values on the **Migrate Database** page:
 - **Migrate to DB Engine:** Select **aurora**.
 - **DB Engine Version:** Select the DB engine version for the Aurora MySQL DB cluster.
 - **DB Instance Class:** Select a DB instance class that has the required storage and capacity for your database, for example `db.r3.large`. Aurora cluster volumes automatically grow as the amount of data in your database increases. An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB). So you only need to select a DB instance class that meets your current storage requirements. For more information, see [Overview of Aurora storage \(p. 64\)](#).
 - **DB Instance Identifier:** Type a name for the DB cluster that is unique for your account in the AWS Region you selected. This identifier is used in the endpoint addresses for the instances in your DB cluster. You might choose to add some intelligence to the name, such as including the AWS Region and DB engine you selected, for example **aurora-cluster1**.

The DB instance identifier has the following constraints:

- It must contain from 1 to 63 alphanumeric characters or hyphens.
- Its first character must be a letter.
- It cannot end with a hyphen or contain two consecutive hyphens.
- It must be unique for all DB instances per AWS account, per AWS Region.
- **Virtual Private Cloud (VPC):** If you have an existing VPC, then you can use that VPC with your Aurora MySQL DB cluster by selecting your VPC identifier, for example `vpc-a464d1c1`. For information on using an existing VPC, see [How to create a VPC for use with Amazon Aurora \(p. 1793\)](#).

Otherwise, you can choose to have Aurora create a VPC for you by selecting **Create a new VPC**.

- **Subnet group:** If you have an existing subnet group, then you can use that subnet group with your Aurora MySQL DB cluster by selecting your subnet group identifier, for example `gs-subnet-group1`.

Otherwise, you can choose to have Aurora create a subnet group for you by selecting **Create a new subnet group**.

- **Public accessibility:** Select **No** to specify that instances in your DB cluster can only be accessed by resources inside of your VPC. Select **Yes** to specify that instances in your DB cluster can be accessed by resources on the public network. The default is **Yes**.

Note

Your production DB cluster might not need to be in a public subnet, because only your application servers require access to your DB cluster. If your DB cluster doesn't need to be in a public subnet, set **Publicly Accessible** to **No**.

- **Availability Zone:** Select the Availability Zone to host the primary instance for your Aurora MySQL DB cluster. To have Aurora select an Availability Zone for you, select **No Preference**.
- **Database Port:** Type the default port to be used when connecting to instances in the Aurora MySQL DB cluster. The default is `3306`.

Note

You might be behind a corporate firewall that doesn't allow access to default ports such as the MySQL default port, `3306`. In this case, provide a port value that your corporate firewall allows. Remember that port value later when you connect to the Aurora MySQL DB cluster.

- **Encryption:** Choose **Enable Encryption** for your new Aurora MySQL DB cluster to be encrypted at rest. If you choose **Enable Encryption**, you must choose a KMS key as the **AWS KMS key** value.

If your DB snapshot isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest.

If your DB snapshot is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. You can specify the encryption key used by the DB snapshot or a different key. You can't create an unencrypted DB cluster from an encrypted DB snapshot.

- **Auto Minor Version Upgrade:** This setting doesn't apply to Aurora MySQL DB clusters.

For more information about engine updates for Aurora MySQL, see [Database engine updates for Amazon Aurora MySQL \(p. 1082\)](#).

4. Choose **Migrate** to migrate your DB snapshot.
5. Choose **Instances**, and then choose the arrow icon to show the DB cluster details and monitor the progress of the migration. On the details page, you can find the cluster endpoint used to connect to the primary instance of the DB cluster. For more information on connecting to an Aurora MySQL DB cluster, see [Connecting to an Amazon Aurora DB cluster \(p. 281\)](#).

AWS CLI

You can migrate a DB snapshot of an RDS for MySQL DB instance to create an Aurora DB cluster. The new DB cluster is then populated with the data from the DB snapshot. The DB snapshot must come from an Amazon RDS DB instance running MySQL version 5.6 or 5.7. For more information, see [Creating a DB snapshot](#).

If the DB snapshot is not in the AWS Region where you want to locate your data, copy the DB snapshot to that AWS Region. For more information, see [Copying a DB snapshot](#).

You can create an Aurora DB cluster from a DB snapshot of an RDS for MySQL DB instance by using the `restore-db-cluster-from-snapshot` command with the following parameters:

- `--db-cluster-identifier`

The name of the DB cluster to create.

- Either `--engine aurora-mysql` for a MySQL 5.7-compatible or 8.0-compatible DB cluster, or `--engine aurora` for a MySQL 5.6-compatible DB cluster
- `--kms-key-id`

The AWS KMS key to optionally encrypt the DB cluster with, depending on whether your DB snapshot is encrypted.

- If your DB snapshot isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest. Otherwise, your DB cluster isn't encrypted.
- If your DB snapshot is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. Otherwise, your DB cluster is encrypted at rest using the encryption key for the DB snapshot.

Note

You can't create an unencrypted DB cluster from an encrypted DB snapshot.

- `--snapshot-identifier`

The Amazon Resource Name (ARN) of the DB snapshot to migrate. For more information about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#).

When you migrate the DB snapshot by using the `RestoreDBClusterFromSnapshot` command, the command creates both the DB cluster and the primary instance.

In this example, you create a MySQL 5.7-compatible DB cluster named `mydbcluster` from a DB snapshot with an ARN set to `mydbsnapshotARN`.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
--db-cluster-identifier mydbcluster \
--snapshot-identifier mydbsnapshotARN \
--engine aurora-mysql
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
--db-cluster-identifier mydbcluster ^
--snapshot-identifier mydbsnapshotARN ^
--engine aurora-mysql
```

In this example, you create a MySQL 5.6-compatible DB cluster named `mydbcluster` from a DB snapshot with an ARN set to `mydbsnapshotARN`.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-from-snapshot \
--db-cluster-identifier mydbcluster \
--snapshot-identifier mydbsnapshotARN \
--engine aurora
```

For Windows:

```
aws rds restore-db-cluster-from-snapshot ^
--db-cluster-identifier mydbcluster ^
--snapshot-identifier mydbsnapshotARN ^
--engine aurora
```

Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica

Aurora uses the MySQL DB engines' binary log replication functionality to create a special type of DB cluster called an Aurora read replica for a source MySQL DB instance. Updates made to the source MySQL DB instance are asynchronously replicated to the Aurora read replica.

We recommend using this functionality to migrate from a MySQL DB instance to an Aurora MySQL DB cluster by creating an Aurora read replica of your source MySQL DB instance. When the replica lag between the MySQL DB instance and the Aurora read replica is 0, you can direct your client applications to the Aurora read replica and then stop replication to make the Aurora read replica a standalone Aurora MySQL DB cluster. Be prepared for migration to take a while, roughly several hours per terabyte (TiB) of data.

For a list of regions where Aurora is available, see [Amazon Aurora](#) in the *AWS General Reference*.

When you create an Aurora read replica of a MySQL DB instance, Amazon RDS creates a DB snapshot of your source MySQL DB instance (private to Amazon RDS, and incurring no charges). Amazon RDS then migrates the data from the DB snapshot to the Aurora read replica. After the data from the DB snapshot has been migrated to the new Aurora MySQL DB cluster, Amazon RDS starts replication between your MySQL DB instance and the Aurora MySQL DB cluster. If your MySQL DB instance contains tables that

use storage engines other than InnoDB, or that use compressed row format, you can speed up the process of creating an Aurora read replica by altering those tables to use the InnoDB storage engine and dynamic row format before you create your Aurora read replica. For more information about the process of copying a MySQL DB snapshot to an Aurora MySQL DB cluster, see [Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using a DB snapshot \(p. 797\)](#).

You can only have one Aurora read replica for a MySQL DB instance.

Note

Replication issues can arise due to feature differences between Amazon Aurora MySQL and the MySQL database engine version of your RDS for MySQL DB instance that is the replication primary. If you encounter an error, you can find help in the [Amazon RDS community forum](#) or by contacting AWS Support.

For more information on MySQL read replicas, see [Working with read replicas of MariaDB, MySQL, and PostgreSQL DB instances](#).

Creating an Aurora read replica

You can create an Aurora read replica for a MySQL DB instance by using the console or the AWS CLI.

Console

To create an Aurora read replica from a source MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the MySQL DB instance that you want to use as the source for your Aurora read replica.
4. For **Actions**, choose **Create Aurora read replica**.
5. Choose the DB cluster specifications you want to use for the Aurora read replica, as described in the following table.

Option	Description
DB instance class	Choose a DB instance class that defines the processing and memory requirements for the primary instance in the DB cluster. For more information about DB instance class options, see Aurora DB instance classes (p. 54) .
Multi-AZ deployment	Choose Create Replica in Different Zone to create a standby replica of the new DB cluster in another Availability Zone in the target AWS Region for failover support. For more information about multiple Availability Zones, see Regions and Availability Zones (p. 11) .
DB instance identifier	Type a name for the primary instance in your Aurora read replica DB cluster. This identifier is used in the endpoint address for the primary instance of the new DB cluster. The DB instance identifier has the following constraints: <ul style="list-style-type: none">• It must contain from 1 to 63 alphanumeric characters or hyphens.• Its first character must be a letter.• It cannot end with a hyphen or contain two consecutive hyphens.

Option	Description
	<ul style="list-style-type: none"> It must be unique for all DB instances for each AWS account, for each AWS Region. <p>Because the Aurora read replica DB cluster is created from a snapshot of the source DB instance, the master user name and master password for the Aurora read replica are the same as the master user name and master password for the source DB instance.</p>
Virtual Private Cloud (VPC)	Select the VPC to host the DB cluster. Select Create new VPC to have Aurora create a VPC for you. For more information, see DB cluster prerequisites (p. 125) .
Subnet group	Select the DB subnet group to use for the DB cluster. Select Create new DB subnet group to have Aurora create a DB subnet group for you. For more information, see DB cluster prerequisites (p. 125) .
Public accessibility	Select Yes to give the DB cluster a public IP address; otherwise, select No. The instances in your DB cluster can be a mix of both public and private DB instances. For more information about hiding instances from public access, see Hiding a DB instance in a VPC from the internet (p. 1789) .
Availability zone	Determine if you want to specify a particular Availability Zone. For more information about Availability Zones, see Regions and Availability Zones (p. 11) .
VPC security groups	Select Create new VPC security group to have Aurora create a VPC security group for you. Select Select existing VPC security groups to specify one or more VPC security groups to secure network access to the DB cluster. For more information, see DB cluster prerequisites (p. 125) .
Database port	Specify the port for applications and utilities to use to access the database. Aurora MySQL DB clusters default to the default MySQL port, 3306. Firewalls at some companies block connections to this port. If your company firewall blocks the default port, choose another port for the new DB cluster.
DB parameter group	Select a DB parameter group for the Aurora MySQL DB cluster. Aurora has a default DB parameter group you can use, or you can create your own DB parameter group. For more information about DB parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 339) .
DB cluster parameter group	Select a DB cluster parameter group for the Aurora MySQL DB cluster. Aurora has a default DB cluster parameter group you can use, or you can create your own DB cluster parameter group. For more information about DB cluster parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 339) .

Option	Description
Encryption	<p>Choose Disable encryption if you don't want your new Aurora DB cluster to be encrypted. Choose Enable encryption for your new Aurora DB cluster to be encrypted at rest. If you choose Enable encryption, you must choose a KMS key as the AWS KMS key value.</p> <p>If your MySQL DB instance isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest.</p> <p>If your MySQL DB instance is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. You can specify the encryption key used by the MySQL DB instance or a different key. You can't create an unencrypted DB cluster from an encrypted MySQL DB instance.</p>
Priority	Choose a failover priority for the DB cluster. If you don't select a value, the default is tier-1 . This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. For more information, see Fault tolerance for an Aurora DB cluster (p. 69) .
Backup retention period	Select the length of time, from 1 to 35 days, that Aurora retains backup copies of the database. Backup copies can be used for point-in-time restores (PITR) of your database down to the second.
Enhanced Monitoring	Choose Enable enhanced monitoring to enable gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 626) .
Monitoring Role	Only available if Enhanced Monitoring is set to Enable enhanced monitoring . Choose the IAM role that you created to permit Aurora to communicate with Amazon CloudWatch Logs for you, or choose Default to have Aurora create a role for you named <code>rds-monitoring-role</code> . For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 626) .
Granularity	Only available if Enhanced Monitoring is set to Enable enhanced monitoring . Set the interval, in seconds, between when metrics are collected for your DB cluster.
Auto minor version upgrade	<p>This setting doesn't apply to Aurora MySQL DB clusters.</p> <p>For more information about engine updates for Aurora MySQL, see Database engine updates for Amazon Aurora MySQL (p. 1082).</p>
Maintenance window	Select Select window and specify the weekly time range during which system maintenance can occur. Or, select No preference for Aurora to assign a period randomly.

6. Choose **Create read replica**.

AWS CLI

To create an Aurora read replica from a source MySQL DB instance, use the [create-db-cluster](#) and [create-db-instance](#) AWS CLI commands to create a new Aurora MySQL DB cluster. When you call the `create-db-cluster` command, include the `--replication-source-identifier` parameter to identify the Amazon Resource Name (ARN) for the source MySQL DB instance. For more information about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#).

Don't specify the master username, master password, or database name as the Aurora read replica uses the same master username, master password, and database name as the source MySQL DB instance.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-replica-cluster --engine aurora \
    --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2 \
    --replication-source-identifier arn:aws:rds:us-west-2:123456789012:db:primary-mysql-
instance
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-replica-cluster --engine aurora ^
    --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2 ^
    --replication-source-identifier arn:aws:rds:us-west-2:123456789012:db:primary-mysql-
instance
```

If you use the console to create an Aurora read replica, then Aurora automatically creates the primary instance for your DB cluster Aurora read replica. If you use the AWS CLI to create an Aurora read replica, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

You can create a primary instance for your DB cluster by using the [create-db-instance](#) AWS CLI command with the following parameters.

- `--db-cluster-identifier`
The name of your DB cluster.
- `--db-instance-class`
The name of the DB instance class to use for your primary instance.
- `--db-instance-identifier`
The name of your primary instance.
- `--engine aurora`

In this example, you create a primary instance named `myreadreplicainstance` for the DB cluster named `myreadreplicacluster`, using the DB instance class specified in `myinstanceclass`.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-cluster-identifier myreadreplicacluster \
    --db-instance-class myinstanceclass \
    --db-instance-identifier myreadreplicainstance \
```

```
--engine aurora
```

For Windows:

```
aws rds create-db-instance ^
--db-cluster-identifier myreadreplicacluster ^
--db-instance-class myinstanceclass ^
--db-instance-identifier myreadreplicainstance ^
--engine aurora
```

RDS API

To create an Aurora read replica from a source MySQL DB instance, use the [CreateDBCluster](#) and [CreateDBInstance](#) Amazon RDS API commands to create a new Aurora DB cluster and primary instance. Do not specify the master username, master password, or database name as the Aurora read replica uses the same master username, master password, and database name as the source MySQL DB instance.

You can create a new Aurora DB cluster for an Aurora read replica from a source MySQL DB instance by using the [CreateDBCluster](#) Amazon RDS API command with the following parameters:

- **DBClusterIdentifier**

The name of the DB cluster to create.

- **DBSubnetGroupName**

The name of the DB subnet group to associate with this DB cluster.

- **Engine=aurora**

- **KmsKeyId**

The AWS KMS key to optionally encrypt the DB cluster with, depending on whether your MySQL DB instance is encrypted.

- If your MySQL DB instance isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest. Otherwise, your DB cluster is encrypted at rest using the default encryption key for your account.
- If your MySQL DB instance is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. Otherwise, your DB cluster is encrypted at rest using the encryption key for the MySQL DB instance.

Note

You can't create an unencrypted DB cluster from an encrypted MySQL DB instance.

- **ReplicationSourceIdentifier**

The Amazon Resource Name (ARN) for the source MySQL DB instance. For more information about Amazon RDS ARNs, see [Amazon Relational Database Service \(Amazon RDS\)](#).

- **VpcSecurityGroupIds**

The list of EC2 VPC security groups to associate with this DB cluster.

In this example, you create a DB cluster named *myreadreplicacluster* from a source MySQL DB instance with an ARN set to *mysqlprimaryARN*, associated with a DB subnet group named *mysubnetgroup* and a VPC security group named *mysecuritygroup*.

Example

```
https://rds.us-east-1.amazonaws.com/
```

```
?Action=CreateDBCluster
&DBClusterIdentifier=myreadreplicacluster
&DBSubnetGroupName=mysubnetgroup
&Engine=aurora
&ReplicationSourceIdentifier=mysqlprimaryARN
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&VpcSecurityGroupIds=mysecuritygroup
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20150927/us-east-1/rds/aws4_request
&X-Amz-Date=20150927T164851Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=6a8f4bd6a98f649c75ea04a6b3929ecc75ac09739588391cd7250f5280e716db
```

If you use the console to create an Aurora read replica, then Aurora automatically creates the primary instance for your DB cluster Aurora read replica. If you use the AWS CLI to create an Aurora read replica, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

You can create a primary instance for your DB cluster by using the [CreateDBInstance](#) Amazon RDS API command with the following parameters:

- **DBClusterIdentifier**
The name of your DB cluster.
- **DBInstanceClass**
The name of the DB instance class to use for your primary instance.
- **DBInstanceIdentifier**
The name of your primary instance.
- **Engine=aurora**

In this example, you create a primary instance named *myreadreplicainstance* for the DB cluster named *myreadreplicacluster*, using the DB instance class specified in *myinstanceclass*.

Example

```
https://rds.us-east-1.amazonaws.com/
?Action=CreateDBInstance
&DBClusterIdentifier=myreadreplicacluster
&DBInstanceClass=myinstanceclass
&DBInstanceIdentifier=myreadreplicainstance
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-09-01
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140424/us-east-1/rds/aws4_request
&X-Amz-Date=20140424T194844Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=bee4aabc750bf7dad0cd9e22b952bd6089d91e2a16592c2293e532eeaab8bc77
```

Viewing an Aurora read replica

You can view the MySQL to Aurora MySQL replication relationships for your Aurora MySQL DB clusters by using the AWS Management Console or the AWS CLI.

Console

To view the primary MySQL DB instance for an Aurora read replica

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster for the Aurora read replica to display its details. The primary MySQL DB instance information is in the **Replication source** field.

The screenshot shows the 'Details' page for an Aurora MySQL DB cluster named 'aurora-mysql-db-cluster'. The page displays various configuration details:

- ARN:** arn:aws:rds:...:aurora-mysql-db-cluster
- DB cluster:** aurora-mysql-db-cluster (available)
- DB cluster role:** Replica
- Replication source:** arn:aws:rds:...:mydbinstance3 (This field is circled in red.)
- Cluster endpoint:** aurora-mysql-db-cluster. rds.amazonaws.com
- Reader endpoint:** aurora-mysql-db-cluster. rds.amazonaws.com
- Port:** 3306

AWS CLI

To view the MySQL to Aurora MySQL replication relationships for your Aurora MySQL DB clusters by using the AWS CLI, use the `describe-db-clusters` and `describe-db-instances` commands.

To determine which MySQL DB instance is the primary, use the `describe-db-clusters` and specify the cluster identifier of the Aurora read replica for the `--db-cluster-identifier` option. Refer to

the `ReplicationSourceIdentifier` element in the output for the ARN of the DB instance that is the replication primary.

To determine which DB cluster is the Aurora read replica, use the `describe-db-instances` and specify the instance identifier of the MySQL DB instance for the `--db-instance-identifier` option. Refer to the `ReadReplicaDBClusterIdentifiers` element in the output for the DB cluster identifier of the Aurora read replica.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-clusters \
--db-cluster-identifier myreadreplicacluster
```

```
aws rds describe-db-instances \
--db-instance-identifier mysqlprimary
```

For Windows:

```
aws rds describe-db-clusters ^
--db-cluster-identifier myreadreplicacluster
```

```
aws rds describe-db-instances ^
--db-instance-identifier mysqlprimary
```

Promoting an Aurora read replica

After migration completes, you can promote the Aurora read replica to a stand-alone DB cluster and direct your client applications to the endpoint for the Aurora read replica. For more information on the Aurora endpoints, see [Amazon Aurora connection management \(p. 32\)](#). Promotion should complete fairly quickly, and you can read from and write to the Aurora read replica during promotion. However, you can't delete the primary MySQL DB instance or unlink the DB Instance and the Aurora read replica during this time.

Before you promote your Aurora read replica, stop any transactions from being written to the source MySQL DB instance, and then wait for the replica lag on the Aurora read replica to reach 0. You can view the replica lag for an Aurora read replica by calling the `SHOW SLAVE STATUS` (Aurora MySQL version 1 and 2) or `SHOW REPLICAS STATUS` (Aurora MySQL version 3) command on your Aurora read replica. Check the **Seconds behind master** value.

You can start writing to the Aurora read replica after write transactions to the primary have stopped and replica lag is 0. If you write to the Aurora read replica before this and you modify tables that are also being modified on the MySQL primary, you risk breaking replication to Aurora. If this happens, you must delete and recreate your Aurora read replica.

Console

To promote an Aurora read replica to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster for the Aurora read replica.
4. For **Actions**, choose **Promote**.
5. Choose **Promote read replica**.

After you promote, confirm that the promotion has completed by using the following procedure.

To confirm that the Aurora read replica was promoted

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Events**.
3. On the **Events** page, verify that there is a **Promoted Read Replica cluster to a stand-alone database cluster** event for the cluster that you promoted.

After promotion is complete, the primary MySQL DB instance and the Aurora read replica are unlinked, and you can safely delete the DB instance if you want.

AWS CLI

To promote an Aurora read replica to a stand-alone DB cluster, use the `promote-read-replica-db-cluster` AWS CLI command.

Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica-db-cluster \
--db-cluster-identifier myreadreplicacluster
```

For Windows:

```
aws rds promote-read-replica-db-cluster ^
--db-cluster-identifier myreadreplicacluster
```

Managing Amazon Aurora MySQL

The following sections discuss managing an Amazon Aurora MySQL DB cluster.

Topics

- [Managing performance and scaling for Amazon Aurora MySQL \(p. 812\)](#)
- [Backtracking an Aurora DB cluster \(p. 816\)](#)
- [Testing Amazon Aurora using fault injection queries \(p. 829\)](#)
- [Altering tables in Amazon Aurora using fast DDL \(p. 832\)](#)
- [Displaying volume status for an Aurora MySQL DB cluster \(p. 837\)](#)

Managing performance and scaling for Amazon Aurora MySQL

Scaling Aurora MySQL DB instances

You can scale Aurora MySQL DB instances in two ways, instance scaling and read scaling. For more information about read scaling, see [Read scaling \(p. 400\)](#).

You can scale your Aurora MySQL DB cluster by modifying the DB instance class for each DB instance in the DB cluster. Aurora MySQL supports several DB instance classes optimized for Aurora. Don't use db.t2

or db.t3 instance classes for larger Aurora clusters of size greater than 40 TB. For the specifications of the DB instance classes supported by Aurora MySQL, see [Aurora DB instance classes \(p. 54\)](#).

Maximum connections to an Aurora MySQL DB instance

The maximum number of connections allowed to an Aurora MySQL DB instance is determined by the `max_connections` parameter in the instance-level parameter group for the DB instance.

The following table lists the resulting default value of `max_connections` for each DB instance class available to Aurora MySQL. You can increase the maximum number of connections to your Aurora MySQL DB instance by scaling the instance up to a DB instance class with more memory, or by setting a larger value for the `max_connections` parameter in the DB parameter group for your instance, up to 16,000.

Instance class	<code>max_connections</code> default value
db.t2.small	45
db.t2.medium	90
db.t3.small	45
db.t3.medium	90
db.t3.large	135
db.t4g.medium	90
db.t4g.large	135
db.r3.large	1000
db.r3.xlarge	2000
db.r3.2xlarge	3000
db.r3.4xlarge	4000
db.r3.8xlarge	5000
db.r4.large	1000
db.r4.xlarge	2000
db.r4.2xlarge	3000
db.r4.4xlarge	4000
db.r4.8xlarge	5000
db.r4.16xlarge	6000
db.r5.large	1000
db.r5.xlarge	2000
db.r5.2xlarge	3000
db.r5.4xlarge	4000

Instance class	max_connections default value		
db.r5.8xlarge	5000		
db.r5.12xlarge	6000		
db.r5.16xlarge	6000		
db.r5.24xlarge	7000		
db.r6g.large	1000		
db.r6g.xlarge	2000		
db.r6g.2xlarge	3000		
db.r6g.4xlarge	4000		
db.r6g.8xlarge	5000		
db.r6g.12xlarge	6000		
db.r6g.16xlarge	6000		
db.x2g.large	2000		
db.x2g.xlarge	3000		
db.x2g.2xlarge	4000		
db.x2g.4xlarge	5000		
db.x2g.8xlarge	6000		
db.x2g.12xlarge	7000		
db.x2g.16xlarge	7000		

If you create a new parameter group to customize your own default for the connection limit, you'll see that the default connection limit is derived using a formula based on the `DBInstanceClassMemory` value. As shown in the preceding table, the formula produces connection limits that increase by 1000 as the memory doubles between progressively larger R3, R4, and R5 instances, and by 45 for different memory sizes of T2 and T3 instances.

The `DBInstanceClassMemory` value represents the memory capacity, in bytes, available for the DB instance. It's a number that Aurora computes internally and isn't directly available for you to query. Aurora reserves some memory in each DB instance for the Aurora management components. This adjustment to the available memory produces a lower `max_connections` value than if the formula used the full memory for the associated DB instance class.

Aurora MySQL and RDS for MySQL DB instances have different amounts of memory overhead. Therefore, the `max_connections` value can be different for Aurora MySQL and RDS for MySQL DB instances that use the same instance class. The values in the table only apply to Aurora MySQL DB instances.

The much lower connectivity limits for T2 and T3 instances are because with Aurora, those instance classes are intended only for development and test scenarios, not for production workloads.

The default connection limits are tuned for systems that use the default values for other major memory consumers, such as the buffer pool and query cache. If you change those other settings for your cluster,

consider adjusting the connection limit to account for the increase or decrease in available memory on the DB instances.

Temporary storage limits for Aurora MySQL

Aurora MySQL stores tables and indexes in the Aurora storage subsystem. Aurora MySQL uses separate temporary storage for non-persistent temporary files. This includes files that are used for such purposes as sorting large datasets during query processing or for index build operations. For more about storage, see [Amazon Aurora storage and reliability \(p. 64\)](#).

The following table shows the maximum amount of temporary storage available for each Aurora MySQL DB instance class.

DB instance class	Maximum temporary storage available (GiB)
db.x2g.16xlarge	1280
db.x2g.12xlarge	960
db.x2g.8xlarge	640
db.x2g.4xlarge	320
db.x2g.2xlarge	160
db.x2g.xlarge	80
db.x2g.large	40
db.r6g.16xlarge	1280
db.r6g.12xlarge	960
db.r6g.8xlarge	640
db.r6g.4xlarge	320
db.r6g.2xlarge	160
db.r6g.xlarge	80
db.r6g.large	32
db.r5.24xlarge	1920
db.r5.16xlarge	1280
db.r5.12xlarge	960
db.r5.8xlarge	640
db.r5.4xlarge	320
db.r5.2xlarge	160
db.r5.xlarge	80
db.r5.large	32
db.r4.16xlarge	1280
db.r4.8xlarge	640

DB instance class	Maximum temporary storage available (GiB)
db.r4.4xlarge	320
db.r4.2xlarge	160
db.r4.xlarge	80
db.r4.large	32
db.t4g.large	32
db.t4g.medium	32
db.t3.large	32
db.t3.medium	32
db.t3.small	32
db.t2.medium	32
db.t2.small	32

Important

These values represent the theoretical maximum amount of free storage on each DB instance. The actual local storage available to you might be lower. Aurora uses some local storage for its management processes, and the DB instance uses some local storage even before you load any data. You can monitor the temporary storage available for a specific DB instance with the [FreeLocalStorage CloudWatch metric](#), described in [Amazon CloudWatch metrics for Amazon Aurora \(p. 633\)](#). You can check the amount of free storage at the present time. You can also chart the amount of free storage over time. Monitoring the free storage over time helps you to determine whether the value is increasing or decreasing, or to find the minimum, maximum, or average values.

Backtracking an Aurora DB cluster

With Amazon Aurora MySQL-Compatible Edition, you can backtrack a DB cluster to a specific time, without restoring data from a backup.

Overview of backtracking

Backtracking "rewinds" the DB cluster to the time you specify. Backtracking is not a replacement for backing up your DB cluster so that you can restore it to a point in time. However, backtracking provides the following advantages over traditional backup and restore:

- You can easily undo mistakes. If you mistakenly perform a destructive action, such as a `DELETE` without a `WHERE` clause, you can backtrack the DB cluster to a time before the destructive action with minimal interruption of service.
- You can backtrack a DB cluster quickly. Restoring a DB cluster to a point in time launches a new DB cluster and restores it from backup data or a DB cluster snapshot, which can take hours. Backtracking a DB cluster doesn't require a new DB cluster and rewinds the DB cluster in minutes.
- You can explore earlier data changes. You can repeatedly backtrack a DB cluster back and forth in time to help determine when a particular data change occurred. For example, you can backtrack a DB cluster three hours and then backtrack forward in time one hour. In this case, the backtrack time is two hours before the original time.

Note

For information about restoring a DB cluster to a point in time, see [Overview of backing up and restoring an Aurora DB cluster \(p. 491\)](#).

Backtrack window

With backtracking, there is a target backtrack window and an actual backtrack window:

- The *target backtrack window* is the amount of time you want to be able to backtrack your DB cluster. When you enable backtracking, you specify a *target backtrack window*. For example, you might specify a target backtrack window of 24 hours if you want to be able to backtrack the DB cluster one day.
- The *actual backtrack window* is the actual amount of time you can backtrack your DB cluster, which can be smaller than the target backtrack window. The actual backtrack window is based on your workload and the storage available for storing information about database changes, called *change records*.

As you make updates to your Aurora DB cluster with backtracking enabled, you generate change records. Aurora retains change records for the target backtrack window, and you pay an hourly rate for storing them. Both the target backtrack window and the workload on your DB cluster determine the number of change records you store. The workload is the number of changes you make to your DB cluster in a given amount of time. If your workload is heavy, you store more change records in your backtrack window than you do if your workload is light.

You can think of your target backtrack window as the goal for the maximum amount of time you want to be able to backtrack your DB cluster. In most cases, you can backtrack the maximum amount of time that you specified. However, in some cases, the DB cluster can't store enough change records to backtrack the maximum amount of time, and your actual backtrack window is smaller than your target. Typically, the actual backtrack window is smaller than the target when you have extremely heavy workload on your DB cluster. When your actual backtrack window is smaller than your target, we send you a notification.

When backtracking is enabled for a DB cluster, and you delete a table stored in the DB cluster, Aurora keeps that table in the backtrack change records. It does this so that you can revert back to a time before you deleted the table. If you don't have enough space in your backtrack window to store the table, the table might be removed from the backtrack change records eventually.

Backtracking time

Aurora always backtracks to a time that is consistent for the DB cluster. Doing so eliminates the possibility of uncommitted transactions when the backtrack is complete. When you specify a time for a backtrack, Aurora automatically chooses the nearest possible consistent time. This approach means that the completed backtrack might not exactly match the time you specify, but you can determine the exact time for a backtrack by using the [describe-db-cluster-backtracks](#) AWS CLI command. For more information, see [Retrieving existing backtracks \(p. 828\)](#).

Backtracking limitations

The following limitations apply to backtracking:

- Backtracking an Aurora DB cluster is available in certain AWS Regions and for specific Aurora MySQL versions only. For more information, see [Backtracking in Aurora \(p. 19\)](#).
- Backtracking is only available for DB clusters that were created with the Backtrack feature enabled. You can enable the Backtrack feature when you create a new DB cluster or restore a snapshot of a DB cluster. For DB clusters that were created with the Backtrack feature enabled, you can create a clone DB cluster with the Backtrack feature enabled. Currently, you can't perform backtracking on DB clusters that were created with the Backtrack feature disabled.
- The limit for a backtrack window is 72 hours.
- Backtracking affects the entire DB cluster. For example, you can't selectively backtrack a single table or a single data update.

- Backtracking isn't supported with binary log (binlog) replication. Cross-Region replication must be disabled before you can configure or use backtracking.
- You can't backtrack a database clone to a time before that database clone was created. However, you can use the original database to backtrack to a time before the clone was created. For more information about database cloning, see [Cloning a volume for an Aurora DB cluster \(p. 402\)](#).
- Backtracking causes a brief DB instance disruption. You must stop or pause your applications before starting a backtrack operation to ensure that there are no new read or write requests. During the backtrack operation, Aurora pauses the database, closes any open connections, and drops any uncommitted reads and writes. It then waits for the backtrack operation to complete.
- Backtracking isn't supported for the following AWS Regions:
 - Africa (Cape Town)
 - China (Ningxia)
 - Asia Pacific (Hong Kong)
 - Europe (Milan)
 - Europe (Stockholm)
 - Middle East (Bahrain)
 - South America (São Paulo)
- You can't restore a cross-Region snapshot of a backtrack-enabled cluster in an AWS Region that doesn't support backtracking.
- You can't use Backtrack with Aurora multi-master clusters.
- If you perform an in-place upgrade for a backtrack-enabled cluster from Aurora MySQL version 1 to version 2, you can't backtrack to a point in time before the upgrade happened.

Upgrade considerations for backtrack-enabled clusters

Backtracking is available for Aurora MySQL 1.*, which is compatible with MySQL 5.6. It's also available for Aurora MySQL 2.06 and higher, which is compatible with MySQL 5.7. Because of the Aurora MySQL 2.* version requirement, if you created the Aurora MySQL 1.* cluster with the Backtrack setting enabled, you can only upgrade to a Backtrack-compatible version of Aurora MySQL 2.*. This requirement affects the following types of upgrade paths:

- You can only restore a snapshot of the Aurora MySQL 1.* DB cluster to a Backtrack-compatible version of Aurora MySQL 2.*.
- You can only perform point-in-time recovery on the Aurora MySQL 1.* DB cluster to restore it to a Backtrack-compatible version of Aurora MySQL 2.*.

These upgrade requirements still apply even if you turn off Backtrack for the Aurora MySQL 1.* cluster.

Configuring backtracking

To use the Backtrack feature, you must enable backtracking and specify a target backtrack window. Otherwise, backtracking is disabled.

For the target backtrack window, specify the amount of time that you want to be able to rewind your database using Backtrack. Aurora tries to retain enough change records to support that window of time.

Console

You can use the console to configure backtracking when you create a new DB cluster. You can also modify a DB cluster to change the backtrack window for a backtrack-enabled cluster. If you turn off backtracking entirely for a cluster by setting the backtrack window to 0, you can't enable backtrack again for that cluster.

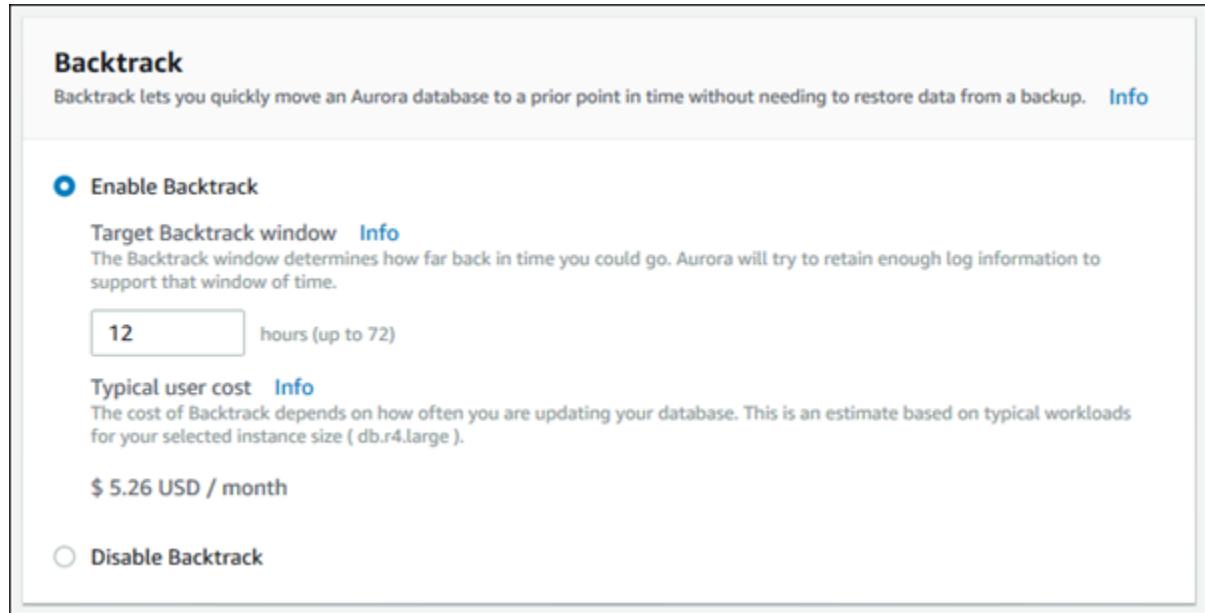

Topics

- [Configuring backtracking with the console when creating a DB cluster \(p. 819\)](#)
- [Configuring backtrack with the console when modifying a DB cluster \(p. 819\)](#)

Configuring backtracking with the console when creating a DB cluster

When you create a new Aurora MySQL DB cluster, backtracking is configured when you choose **Enable Backtrack** and specify a **Target Backtrack window** value that is greater than zero in the **Backtrack** section.

To create a DB cluster, follow the instructions in [Creating an Amazon Aurora DB cluster \(p. 125\)](#). The following image shows the **Backtrack** section.

When you create a new DB cluster, Aurora has no data for the DB cluster's workload. So it can't estimate a cost specifically for the new DB cluster. Instead, the console presents a typical user cost for the specified target backtrack window based on a typical workload. The typical cost is meant to provide a general reference for the cost of the Backtrack feature.

Important

Your actual cost might not match the typical cost, because your actual cost is based on your DB cluster's workload.

Configuring backtrack with the console when modifying a DB cluster

You can modify backtracking for a DB cluster using the console.

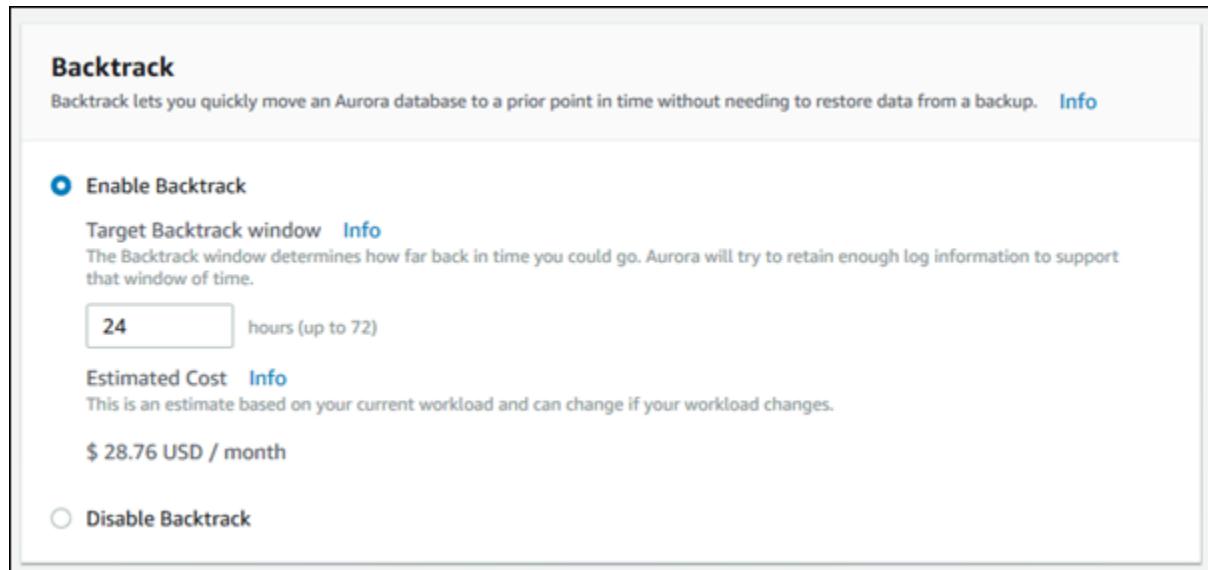

Note

Currently, you can modify backtracking only for a DB cluster that has the Backtrack feature enabled. The **Backtrack** section doesn't appear for a DB cluster that was created with the Backtrack feature disabled or if the Backtrack feature has been disabled for the DB cluster.

To modify backtracking for a DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases**.

3. Choose the cluster that you want to modify, and choose **Modify**.
4. For **Target Backtrack window**, modify the amount of time that you want to be able to backtrack. The limit is 72 hours.

The console shows the estimated cost for the amount of time you specified based on the DB cluster's past workload:

- If backtracking was disabled on the DB cluster, the cost estimate is based on the `VolumeWriteIOPS` metric for the DB cluster in Amazon CloudWatch.
 - If backtracking was enabled previously on the DB cluster, the cost estimate is based on the `BacktrackChangeRecordsCreationRate` metric for the DB cluster in Amazon CloudWatch.
5. Choose **Continue**.
 6. For **Scheduling of Modifications**, choose one of the following:
 - **Apply during the next scheduled maintenance window** – Wait to apply the **Target Backtrack window** modification until the next maintenance window.
 - **Apply immediately** – Apply the **Target Backtrack window** modification as soon as possible.
 7. Choose **Modify cluster**.

AWS CLI

When you create a new Aurora MySQL DB cluster using the `create-db-cluster` AWS CLI command, backtracking is configured when you specify a `--backtrack-window` value that is greater than zero. The `--backtrack-window` value specifies the target backtrack window. For more information, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

You can also specify the `--backtrack-window` value using the following AWS CLI commands:

- `modify-db-cluster`
- `restore-db-cluster-from-s3`
- `restore-db-cluster-from-snapshot`
- `restore-db-cluster-to-point-in-time`

The following procedure describes how to modify the target backtrack window for a DB cluster using the AWS CLI.

To modify the target backtrack window for a DB cluster using the AWS CLI

- Call the [modify-db-cluster](#) AWS CLI command and supply the following values:
 - `--db-cluster-identifier` – The name of the DB cluster.
 - `--backtrack-window` – The maximum number of seconds that you want to be able to backtrack the DB cluster.

The following example sets the target backtrack window for `sample-cluster` to one day (86,400 seconds).

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
--db-cluster-identifier sample-cluster \
--backtrack-window 86400
```

For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier sample-cluster ^
--backtrack-window 86400
```

Note

Currently, you can enable backtracking only for a DB cluster that was created with the Backtrack feature enabled.

RDS API

When you create a new Aurora MySQL DB cluster using the [CreateDBCluster](#) Amazon RDS API operation, backtracking is configured when you specify a `BacktrackWindow` value that is greater than zero. The `BacktrackWindow` value specifies the target backtrack window for the DB cluster specified in the `DBClusterIdentifier` value. For more information, see [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

You can also specify the `BacktrackWindow` value using the following API operations:

- [ModifyDBCluster](#)
- [RestoreDBClusterFromS3](#)
- [RestoreDBClusterFromSnapshot](#)
- [RestoreDBClusterToPointInTime](#)

Note

Currently, you can enable backtracking only for a DB cluster that was created with the Backtrack feature enabled.

Performing a backtrack

You can backtrack a DB cluster to a specified backtrack time stamp. If the backtrack time stamp isn't earlier than the earliest possible backtrack time, and isn't in the future, the DB cluster is backtracked to that time stamp.

Otherwise, an error typically occurs. Also, if you try to backtrack a DB cluster for which binary logging is enabled, an error typically occurs unless you've chosen to force the backtrack to occur. Forcing a backtrack to occur can interfere with other operations that use binary logging.

Important

Backtracking doesn't generate binlog entries for the changes that it makes. If you have binary logging enabled for the DB cluster, backtracking might not be compatible with your binlog implementation.

Note

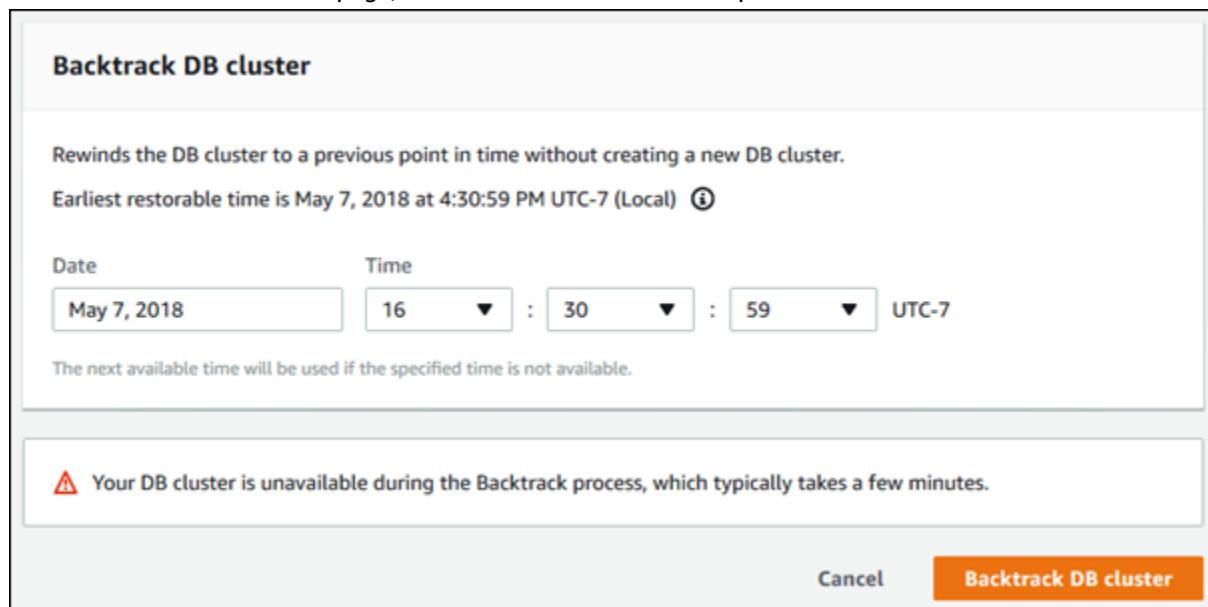

For database clones, you can't backtrack the DB cluster earlier than the date and time when the clone was created. For more information about database cloning, see [Cloning a volume for an Aurora DB cluster \(p. 402\)](#).

[Console](#)

The following procedure describes how to perform a backtrack operation for a DB cluster using the console.

To perform a backtrack operation using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Instances**.
3. Choose the primary instance for the DB cluster that you want to backtrack.
4. For **Actions**, choose **Backtrack DB cluster**.
5. On the **Backtrack DB cluster** page, enter the backtrack time stamp to backtrack the DB cluster to.

6. Choose **Backtrack DB cluster**.

[AWS CLI](#)

The following procedure describes how to backtrack a DB cluster using the AWS CLI.

To backtrack a DB cluster using the AWS CLI

- Call the `backtrack-db-cluster` AWS CLI command and supply the following values:

- `--db-cluster-identifier` – The name of the DB cluster.
- `--backtrack-to` – The backtrack time stamp to backtrack the DB cluster to, specified in ISO 8601 format.

The following example backtracks the DB cluster `sample-cluster` to March 19, 2018, at 10 a.m.

For Linux, macOS, or Unix:

```
aws rds backtrack-db-cluster \
--db-cluster-identifier sample-cluster \
--backtrack-to 2018-03-19T10:00:00+00:00
```

For Windows:

```
aws rds backtrack-db-cluster ^
--db-cluster-identifier sample-cluster ^
--backtrack-to 2018-03-19T10:00:00+00:00
```

RDS API

To backtrack a DB cluster using the Amazon RDS API, use the `BacktrackDBCluster` operation. This operation backtracks the DB cluster specified in the `DBClusterIdentifier` value to the specified time.

Monitoring backtracking

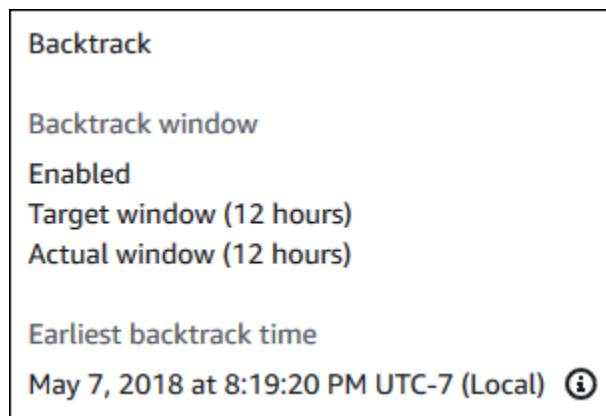

You can view backtracking information and monitor backtracking metrics for a DB cluster.

Console

To view backtracking information and monitor backtracking metrics using the console

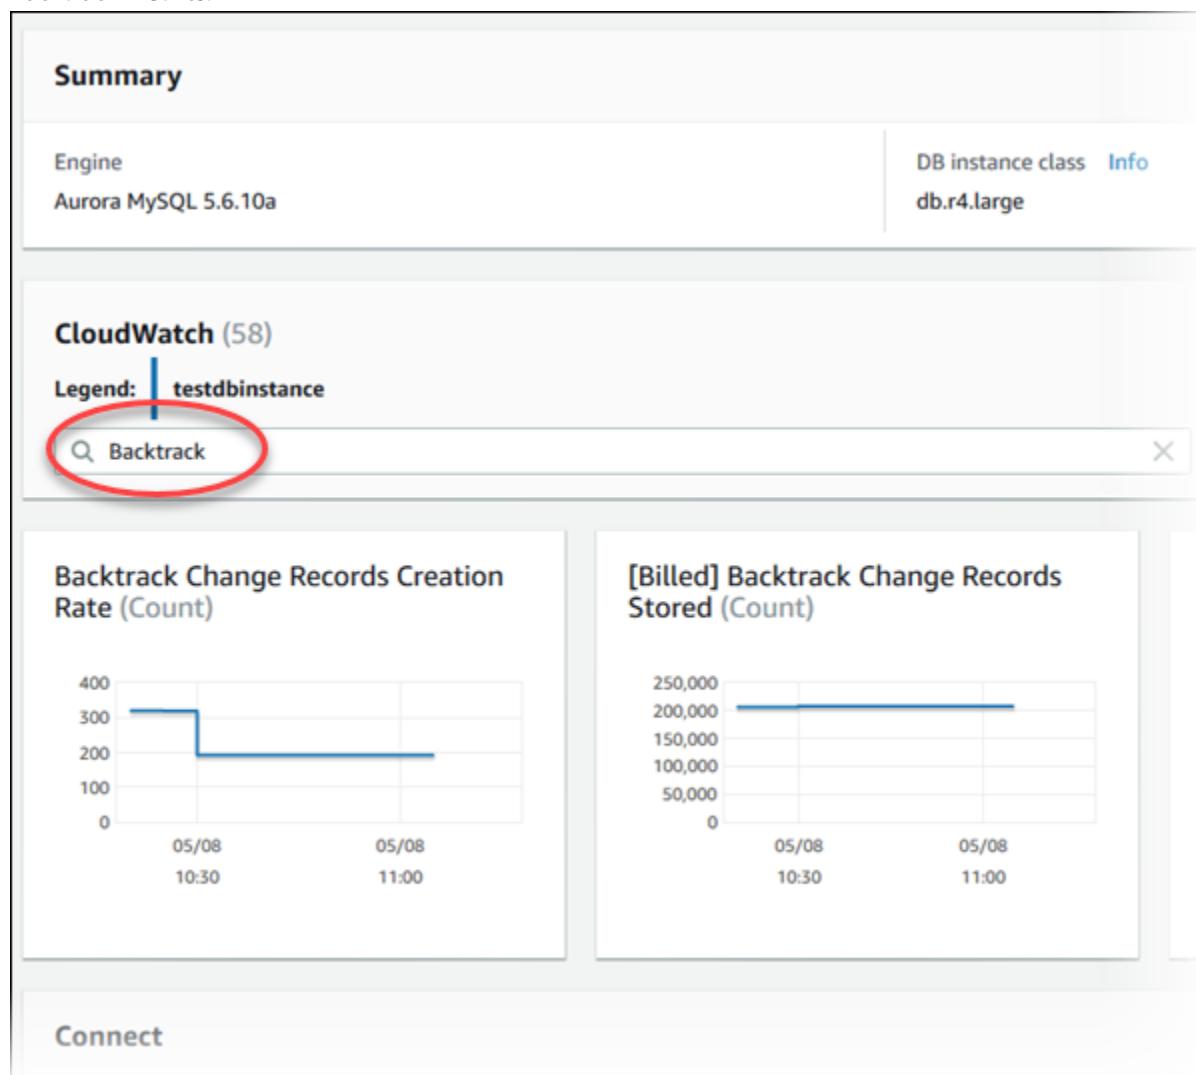

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases**.
3. Choose the DB cluster name to open information about it.

The backtrack information is in the **Backtrack** section.

When backtracking is enabled, the following information is available:

- **Target window** – The current amount of time specified for the target backtrack window. The target is the maximum amount of time that you can backtrack if there is sufficient storage.
 - **Actual window** – The actual amount of time you can backtrack, which can be smaller than the target backtrack window. The actual backtrack window is based on your workload and the storage available for retaining backtrack change records.
 - **Earliest backtrack time** – The earliest possible backtrack time for the DB cluster. You can't backtrack the DB cluster to a time before the displayed time.
4. Do the following to view backtracking metrics for the DB cluster:
- a. In the navigation pane, choose **Instances**.
 - b. Choose the name of the primary instance for the DB cluster to display its details.
 - c. In the **CloudWatch** section, type **Backtrack** into the **CloudWatch** box to show only the Backtrack metrics.

The following metrics are displayed:

- **Backtrack Change Records Creation Rate (Count)** – This metric shows the number of backtrack change records created over five minutes for your DB cluster. You can use this metric to estimate the backtrack cost for your target backtrack window.
- **[Billed] Backtrack Change Records Stored (Count)** – This metric shows the actual number of backtrack change records used by your DB cluster.
- **Backtrack Window Actual (Minutes)** – This metric shows whether there is a difference between the target backtrack window and the actual backtrack window. For example, if your target backtrack window is 2 hours (120 minutes), and this metric shows that the actual backtrack window is 100 minutes, then the actual backtrack window is smaller than the target.
- **Backtrack Window Alert (Count)** – This metric shows how often the actual backtrack window is smaller than the target backtrack window for a given period of time.

Note

The following metrics might lag behind the current time:

- **Backtrack Change Records Creation Rate (Count)**
- **[Billed] Backtrack Change Records Stored (Count)**

AWS CLI

The following procedure describes how to view backtrack information for a DB cluster using the AWS CLI.

To view backtrack information for a DB cluster using the AWS CLI

- Call the [describe-db-clusters](#) AWS CLI command and supply the following values:
 - `--db-cluster-identifier` – The name of the DB cluster.

The following example lists backtrack information for `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds describe-db-clusters \
    --db-cluster-identifier sample-cluster
```

For Windows:

```
aws rds describe-db-clusters ^
    --db-cluster-identifier sample-cluster
```

RDS API

To view backtrack information for a DB cluster using the Amazon RDS API, use the [DescribeDBClusters](#) operation. This operation returns backtrack information for the DB cluster specified in the `DBClusterIdentifier` value.

Subscribing to a backtrack event with the console

The following procedure describes how to subscribe to a backtrack event using the console. The event sends you an email or text notification when your actual backtrack window is smaller than your target backtrack window.

To view backtrack information using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Event subscriptions**.
3. Choose **Create event subscription**.
4. In the **Name** box, type a name for the event subscription, and ensure that **Yes** is selected for **Enabled**.
5. In the **Target** section, choose **New email topic**.
6. For **Topic name**, type a name for the topic, and for **With these recipients**, enter the email addresses or phone numbers to receive the notifications.
7. In the **Source** section, choose **Instances** for **Source type**.
8. For **Instances to include**, choose **Select specific instances**, and choose your DB instance.
9. For **Event categories to include**, choose **Select specific event categories**, and choose **backtrack**.

Your page should look similar to the following page.

Retrieving existing backtracks

You can retrieve information about existing backtracks for a DB cluster. This information includes the unique identifier of the backtrack, the date and time backtracked to and from, the date and time the backtrack was requested, and the current status of the backtrack.

Note

Currently, you can't retrieve existing backtracks using the console.

AWS CLI

The following procedure describes how to retrieve existing backtracks for a DB cluster using the AWS CLI.

To retrieve existing backtracks using the AWS CLI

- Call the [describe-db-cluster-backtracks](#) AWS CLI command and supply the following values:
 - `--db-cluster-identifier` – The name of the DB cluster.

The following example retrieves existing backtracks for `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-backtracks \
  --db-cluster-identifier sample-cluster
```

For Windows:

```
aws rds describe-db-cluster-backtracks ^
  --db-cluster-identifier sample-cluster
```

RDS API

To retrieve information about the backtracks for a DB cluster using the Amazon RDS API, use the [DescribeDBClusterBacktracks](#) operation. This operation returns information about backtracks for the DB cluster specified in the `DBClusterIdentifier` value.

Disabling backtracking for a DB cluster

You can disable the Backtrack feature for a DB cluster.

Console

You can disable backtracking for a DB cluster using the console. After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

To disable the Backtrack feature for a DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. Choose **Databases**.
3. Choose the cluster you want to modify, and choose **Modify**.
4. In the **Backtrack** section, choose **Disable Backtrack**.
5. Choose **Continue**.
6. For **Scheduling of Modifications**, choose one of the following:
 - **Apply during the next scheduled maintenance window** – Wait to apply the modification until the next maintenance window.
 - **Apply immediately** – Apply the modification as soon as possible.
7. Choose **Modify Cluster**.

AWS CLI

You can disable the Backtrack feature for a DB cluster using the AWS CLI by setting the target backtrack window to 0 (zero). After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

To modify the target backtrack window for a DB cluster using the AWS CLI

- Call the [modify-db-cluster](#) AWS CLI command and supply the following values:
 - **--db-cluster-identifier** – The name of the DB cluster.
 - **--backtrack-window** – specify 0 to turn off backtracking.

The following example disables the Backtrack feature for the `sample-cluster` by setting `--backtrack-window` to 0.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
--db-cluster-identifier sample-cluster \
--backtrack-window 0
```

For Windows:

```
aws rds modify-db-cluster ^
--db-cluster-identifier sample-cluster ^
--backtrack-window 0
```

RDS API

To disable the Backtrack feature for a DB cluster using the Amazon RDS API, use the [ModifyDBCluster](#) operation. Set the `BacktrackWindow` value to 0 (zero), and specify the DB cluster in the `DBClusterIdentifier` value. After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

Testing Amazon Aurora using fault injection queries

You can test the fault tolerance of your Amazon Aurora DB cluster by using fault injection queries. Fault injection queries are issued as SQL commands to an Amazon Aurora instance and they enable you to schedule a simulated occurrence of one of the following events:

- A crash of a writer or reader DB instance
- A failure of an Aurora Replica
- A disk failure
- Disk congestion

When a fault injection query specifies a crash, it forces a crash of the Aurora DB instance. The other fault injection queries result in simulations of failure events, but don't cause the event to occur. When you submit a fault injection query, you also specify an amount of time for the failure event simulation to occur for.

You can submit a fault injection query to one of your Aurora Replica instances by connecting to the endpoint for the Aurora Replica. For more information, see [Amazon Aurora connection management \(p. 32\)](#).

Testing an instance crash

You can force a crash of an Amazon Aurora instance using the `ALTER SYSTEM CRASH` fault injection query.

For this fault injection query, a failover will not occur. If you want to test a failover, then you can choose the `Failover` instance action for your DB cluster in the RDS console, or use the `failover-db-cluster` AWS CLI command or the `FailoverDBCluster` RDS API operation.

Syntax

```
ALTER SYSTEM CRASH [ INSTANCE | DISPATCHER | NODE ];
```

Options

This fault injection query takes one of the following crash types:

- **INSTANCE** — A crash of the MySQL-compatible database for the Amazon Aurora instance is simulated.
- **DISPATCHER** — A crash of the dispatcher on the writer instance for the Aurora DB cluster is simulated. The *dispatcher* writes updates to the cluster volume for an Amazon Aurora DB cluster.
- **NODE** — A crash of both the MySQL-compatible database and the dispatcher for the Amazon Aurora instance is simulated. For this fault injection simulation, the cache is also deleted.

The default crash type is `INSTANCE`.

Testing an Aurora replica failure

You can simulate the failure of an Aurora Replica using the `ALTER SYSTEM SIMULATE READ REPLICA FAILURE` fault injection query.

An Aurora Replica failure will block all requests to an Aurora Replica or all Aurora Replicas in the DB cluster for a specified time interval. When the time interval completes, the affected Aurora Replicas will be automatically synced up with master instance.

Syntax

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT READ REPLICA FAILURE
```

```
[ TO ALL | TO "replica name" ]
FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };
```

Options

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of requests to block during the failure event. This value can be a double between 0 and 100. If you specify 0, then no requests are blocked. If you specify 100, then all requests are blocked.
- **Failure type** — The type of failure to simulate. Specify `TO ALL` to simulate failures for all Aurora Replicas in the DB cluster. Specify `TO` and the name of the Aurora Replica to simulate a failure of a single Aurora Replica. The default failure type is `TO ALL`.
- **quantity** — The amount of time for which to simulate the Aurora Replica failure. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified unit. For example, `20 MINUTE` will result in the simulation running for 20 minutes.

Note

Take care when specifying the time interval for your Aurora Replica failure event. If you specify too long of a time interval, and your writer instance writes a large amount of data during the failure event, then your Aurora DB cluster might assume that your Aurora Replica has crashed and replace it.

Testing a disk failure

You can simulate a disk failure for an Aurora DB cluster using the `ALTER SYSTEM SIMULATE DISK FAILURE` fault injection query.

During a disk failure simulation, the Aurora DB cluster randomly marks disk segments as faulting. Requests to those segments will be blocked for the duration of the simulation.

Syntax

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT DISK FAILURE
[ IN DISK index | NODE index ]
FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };
```

Options

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of the disk to mark as faulting during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as faulting. If you specify 100, then the entire disk is marked as faulting.
- **DISK index** — A specific logical block of data to simulate the failure event for. If you exceed the range of available logical blocks of data, you will receive an error that tells you the maximum index value that you can specify. For more information, see [Displaying volume status for an Aurora MySQL DB cluster \(p. 837\)](#).
- **NODE index** — A specific storage node to simulate the failure event for. If you exceed the range of available storage nodes, you will receive an error that tells you the maximum index value that you can specify. For more information, see [Displaying volume status for an Aurora MySQL DB cluster \(p. 837\)](#).
- **quantity** — The amount of time for which to simulate the disk failure. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified unit. For example, `20 MINUTE` will result in the simulation running for 20 minutes.

Testing disk congestion

You can simulate a disk failure for an Aurora DB cluster using the `ALTER SYSTEM SIMULATE DISK CONGESTION` fault injection query.

During a disk congestion simulation, the Aurora DB cluster randomly marks disk segments as congested. Requests to those segments will be delayed between the specified minimum and maximum delay time for the duration of the simulation.

Syntax

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT DISK CONGESTION
  BETWEEN minimum AND maximum MILLISECONDS
  [ IN DISK index | NODE index ]
  FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };
```

Options

This fault injection query takes the following parameters:

- **`percentage_of_failure`** — The percentage of the disk to mark as congested during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as congested. If you specify 100, then the entire disk is marked as congested.
- **`DISK index Or NODE index`** — A specific disk or node to simulate the failure event for. If you exceed the range of indexes for the disk or node, you will receive an error that tells you the maximum index value that you can specify.
- **`minimum And maximum`** — The minimum and maximum amount of congestion delay, in milliseconds. Disk segments marked as congested will be delayed for a random amount of time within the range of the minimum and maximum amount of milliseconds for the duration of the simulation.
- **`quantity`** — The amount of time for which to simulate the disk congestion. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified time unit. For example, `20 MINUTE` will result in the simulation running for 20 minutes.

Altering tables in Amazon Aurora using fast DDL

Amazon Aurora includes optimizations to run an `ALTER TABLE` operation in place, nearly instantaneously. The operation completes without requiring the table to be copied and without having a material impact on other DML statements. Because the operation doesn't consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes.

Aurora MySQL version 3 is compatible with the MySQL 8.0 feature called instant DDL. Aurora MySQL versions 1 and 2 use a different implementation called fast DDL.

Topics

- [Instant DDL \(Aurora MySQL version 3\) \(p. 832\)](#)
- [Fast DDL \(Aurora MySQL version 1 and 2\) \(p. 834\)](#)

Instant DDL (Aurora MySQL version 3)

The optimization performed by Aurora MySQL version 3 to improve the efficiency of some DDL operations is called instant DDL.

Aurora MySQL version 3 is compatible with the instant DDL from community MySQL 8.0. You perform an instant DDL operation by using the clause ALGORITHM=INSTANT with the ALTER TABLE statement. For syntax and usage details about instant DDL, see [ALTER TABLE](#) and [Online DDL Operations](#) in the MySQL documentation.

The following examples demonstrate the instant DDL feature. The ALTER TABLE statements create and drop indexes, add columns, and change default column values. The examples include both regular and virtual columns, and both regular and partitioned tables. At each step, you can see the results by issuing SHOW CREATE TABLE and DESCRIBE statements.

```
mysql> CREATE TABLE t1 (a INT, b INT, KEY(b)) PARTITION BY KEY(b) PARTITIONS 6;
Query OK, 0 rows affected (0.02 sec)

mysql> ALTER TABLE t1 DROP KEY b, ADD KEY b(b) USING BTREE, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t1 RENAME TO t2, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ALTER COLUMN b SET DEFAULT 100, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t2 ALTER COLUMN b DROP DEFAULT, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ADD COLUMN c ENUM('a', 'b', 'c'), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 MODIFY COLUMN c ENUM('a', 'b', 'c', 'd', 'e'), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ADD COLUMN (d INT GENERATED ALWAYS AS (a + 1) VIRTUAL), ALGORITHM =
INSTANT;
Query OK, 0 rows affected (0.02 sec)

mysql> ALTER TABLE t2 ALTER COLUMN a SET DEFAULT 20,
->      ALTER COLUMN b SET DEFAULT 200, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t2 (a INT, b INT) PARTITION BY LIST(a)(
->      PARTITION mypart1 VALUES IN (1,3,5),
->      PARTITION MyPart2 VALUES IN (2,4,6)
-> );
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE t3 ALTER COLUMN a SET DEFAULT 20, ALTER COLUMN b SET DEFAULT 200,
ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (a INT, b INT) PARTITION BY RANGE(a)
->      (PARTITION p0 VALUES LESS THAN(100), PARTITION p1 VALUES LESS THAN(1000),
->      PARTITION p2 VALUES LESS THAN MAXVALUE);
Query OK, 0 rows affected (0.05 sec)

mysql> ALTER TABLE t4 ALTER COLUMN a SET DEFAULT 20,
->      ALTER COLUMN b SET DEFAULT 200, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

/* Sub-partitioning example */
mysql> CREATE TABLE ts (id INT, purchased DATE, a INT, b INT)
->      PARTITION BY RANGE( YEAR(purchased) )
->          SUBPARTITION BY HASH( TO_DAYS(purchased) )
->              SUBPARTITIONS 2 (
->                  PARTITION p0 VALUES LESS THAN (1990),
```

```
-->      PARTITION p1 VALUES LESS THAN (2000),
-->      PARTITION p2 VALUES LESS THAN MAXVALUE
-->    );
Query OK, 0 rows affected (0.10 sec)

mysql> ALTER TABLE ts ALTER COLUMN a SET DEFAULT 20,
-->      ALTER COLUMN b SET DEFAULT 200, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)
```

Fast DDL (Aurora MySQL version 1 and 2)

In MySQL, many data definition language (DDL) operations have a significant performance impact.

For example, suppose that you use an `ALTER TABLE` operation to add a column to a table. Depending on the algorithm specified for the operation, this operation can involve the following:

- Creating a full copy of the table
- Creating a temporary table to process concurrent data manipulation language (DML) operations
- Rebuilding all indexes for the table
- Applying table locks while applying concurrent DML changes
- Slowing concurrent DML throughput

The optimization performed by Aurora MySQL version 1 and 2 to improve the efficiency of some DDL operations is called fast DDL.

In Aurora MySQL version 3, Aurora uses the MySQL 8.0 feature called instant DDL. Aurora MySQL versions 1 and 2 use a different implementation called fast DDL.

Important

Currently, Aurora lab mode must be enabled to use fast DDL for Aurora MySQL. We don't recommend using fast DDL for production DB clusters. For information about enabling Aurora lab mode, see [Amazon Aurora MySQL lab mode \(p. 1032\)](#).

Fast DDL limitations

Currently, fast DDL has the following limitations:

- Fast DDL only supports adding nullable columns, without default values, to the end of an existing table.
- Fast DDL doesn't work for partitioned tables.
- Fast DDL doesn't work for InnoDB tables that use the REDUNDANT row format.
- Fast DDL doesn't work for tables with full-text search indexes.
- If the maximum possible record size for the DDL operation is too large, fast DDL is not used. A record size is too large if it is greater than half the page size. The maximum size of a record is computed by adding the maximum sizes of all columns. For variable sized columns, according to InnoDB standards, extern bytes are not included for computation.

Note

The maximum record size check was added in Aurora 1.15.

Fast DDL syntax

```
ALTER TABLE tbl_name ADD COLUMN col_name column_definition
```

This statement takes the following options:

- **tbl_name** — The name of the table to be modified.
- **col_name** — The name of the column to be added.
- **col_definition** — The definition of the column to be added.

Note

You must specify a nullable column definition without a default value. Otherwise, fast DDL isn't used.

Fast DDL examples

The following examples demonstrate the speedup from fast DDL operations. The first SQL example runs `ALTER TABLE` statements on a large table without using fast DDL. This operation takes substantial time. A CLI example shows how to enable fast DDL for the cluster. Then another SQL example runs the same `ALTER TABLE` statements on an identical table. With fast DDL enabled, the operation is very fast.

This example uses the `ORDERS` table from the TPC-H benchmark, containing 150 million rows. This cluster intentionally uses a relatively small instance class, to demonstrate how long `ALTER TABLE` statements can take when you can't use fast DDL. The example creates a clone of the original table containing identical data. Checking the `aurora_lab_mode` setting confirms that the cluster can't use fast DDL, because lab mode isn't enabled. Then `ALTER TABLE ADD COLUMN` statements take substantial time to add new columns at the end of the table.

```
mysql> create table orders_regular_ddl like orders;
Query OK, 0 rows affected (0.06 sec)

mysql> insert into orders_regular_ddl select * from orders;
Query OK, 150000000 rows affected (1 hour 1 min 25.46 sec)

mysql> select @@aurora_lab_mode;
+-----+
| @@aurora_lab_mode |
+-----+
|          0 |
+-----+

mysql> ALTER TABLE orders_regular_ddl ADD COLUMN o_refunded boolean;
Query OK, 0 rows affected (40 min 31.41 sec)

mysql> ALTER TABLE orders_regular_ddl ADD COLUMN o_coverletter varchar(512);
Query OK, 0 rows affected (40 min 44.45 sec)
```

This example does the same preparation of a large table as the previous example. However, you can't simply enable lab mode within an interactive SQL session. That setting must be enabled in a custom parameter group. Doing so requires switching out of the `mysql` session and running some AWS CLI commands or using the AWS Management Console.

```
mysql> create table orders_fast_ddl like orders;
Query OK, 0 rows affected (0.02 sec)

mysql> insert into orders_fast_ddl select * from orders;
Query OK, 150000000 rows affected (58 min 3.25 sec)

mysql> set aurora_lab_mode=1;
ERROR 1238 (HY000): Variable 'aurora_lab_mode' is a read only variable
```

Enabling lab mode for the cluster requires some work with a parameter group. This AWS CLI example uses a cluster parameter group, to ensure that all DB instances in the cluster use the same value for the lab mode setting.

```
$ aws rds create-db-cluster-parameter-group \
--db-parameter-group-family aurora5.6 \
--db-cluster-parameter-group-name lab-mode-enabled-56 --description 'TBD'
$ aws rds describe-db-cluster-parameters \
--db-cluster-parameter-group-name lab-mode-enabled-56 \
--query '*[].[ParameterName,ParameterValue]' \
--output text | grep aurora_lab_mode
aurora_lab_mode 0
$ aws rds modify-db-cluster-parameter-group \
--db-cluster-parameter-group-name lab-mode-enabled-56 \
--parameters ParameterName=aurora_lab_mode,ParameterValue=1,ApplyMethod=pending-reboot
{
    "DBClusterParameterGroupName": "lab-mode-enabled-56"
}

# Assign the custom parameter group to the cluster that's going to use fast DDL.
$ aws rds modify-db-cluster --db-cluster-identifier tpch100g \
--db-cluster-parameter-group-name lab-mode-enabled-56
{
    "DBClusterIdentifier": "tpch100g",
    "DBClusterParameterGroup": "lab-mode-enabled-56",
    "Engine": "aurora",
    "EngineVersion": "5.6.mysql_aurora.1.22.2",
    "Status": "available"
}

# Reboot the primary instance for the cluster tpch100g:
$ aws rds reboot-db-instance --db-instance-identifier instance-2020-12-22-5208
{
    "DBInstanceIdentifier": "instance-2020-12-22-5208",
    "DBInstanceState": "rebooting"
}

$ aws rds describe-db-clusters --db-cluster-identifier tpch100g \
--query '*[].[DBClusterParameterGroup]' --output text
lab-mode-enabled-56

$ aws rds describe-db-cluster-parameters \
--db-cluster-parameter-group-name lab-mode-enabled-56 \
--query '*[].[ParameterName:ParameterName,ParameterValue:ParameterValue]' \
--output text | grep aurora_lab_mode
aurora_lab_mode 1
```

The following example shows the remaining steps after the parameter group change takes effect. It tests the `aurora_lab_mode` setting to make sure that the cluster can use fast DDL. Then it runs `ALTER TABLE` statements to add columns to the end of another large table. This time, the statements finish very quickly.

```
mysql> select @@aurora_lab_mode;
+-----+
| @@aurora_lab_mode |
+-----+
|          1         |
+-----+

mysql> ALTER TABLE orders_fast_ddl ADD COLUMN o_refunded boolean;
Query OK, 0 rows affected (1.51 sec)

mysql> ALTER TABLE orders_fast_ddl ADD COLUMN o_coverletter varchar(512);
Query OK, 0 rows affected (0.40 sec)
```

Displaying volume status for an Aurora MySQL DB cluster

In Amazon Aurora, a DB cluster volume consists of a collection of logical blocks. Each of these represents 10 gigabytes of allocated storage. These blocks are called *protection groups*.

The data in each protection group is replicated across six physical storage devices, called *storage nodes*. These storage nodes are allocated across three Availability Zones (AZs) in the AWS Region where the DB cluster resides. In turn, each storage node contains one or more logical blocks of data for the DB cluster volume. For more information about protection groups and storage nodes, see [Introducing the Aurora storage engine](#) on the AWS Database Blog.

You can simulate the failure of an entire storage node, or a single logical block of data within a storage node. To do so, you use the `ALTER SYSTEM SIMULATE DISK FAILURE` fault injection statement. For the statement, you specify the index value of a specific logical block of data or storage node. However, if you specify an index value greater than the number of logical blocks of data or storage nodes used by the DB cluster volume, the statement returns an error. For more information about fault injection queries, see [Testing Amazon Aurora using fault injection queries \(p. 829\)](#).

You can avoid that error by using the `SHOW VOLUME STATUS` statement. The statement returns two server status variables, `Disks` and `Nodes`. These variables represent the total number of logical blocks of data and storage nodes, respectively, for the DB cluster volume.

Note

The `SHOW VOLUME STATUS` statement is available for Aurora version 1.12 and later. For more information about Aurora versions, see [Database engine updates for Amazon Aurora MySQL \(p. 1082\)](#).

Syntax

```
SHOW VOLUME STATUS
```

Example

The following example illustrates a typical `SHOW VOLUME STATUS` result.

```
mysql> SHOW VOLUME STATUS;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Disks         | 96    |
| Nodes         | 74    |
+-----+-----+
```

Tuning Aurora MySQL with wait events and thread states

Wait events and thread states are an important tuning tool for Aurora MySQL. If you can find out why sessions are waiting for resources and what they are doing, you are better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions.

Important

The wait events and thread states in this section are specific to Aurora MySQL. Use the information in this section to tune only Amazon Aurora, not Amazon RDS for MySQL.

Some wait events in this section have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave differently. For example, Amazon Aurora storage works different from open source storage, so storage-related wait events indicate different resource conditions.

Topics

- [Essential concepts for Aurora MySQL tuning \(p. 838\)](#)
- [Tuning Aurora MySQL with wait events \(p. 840\)](#)
- [Tuning Aurora MySQL with thread states \(p. 876\)](#)

Essential concepts for Aurora MySQL tuning

Before you tune your Aurora MySQL database, make sure to learn what wait events and thread states are and why they occur. Also review the basic memory and disk architecture of Aurora MySQL when using the InnoDB storage engine. For a helpful architecture diagram, see the [MySQL Reference Manual](#).

Topics

- [Aurora MySQL wait events \(p. 838\)](#)
- [Aurora MySQL thread states \(p. 839\)](#)
- [Aurora MySQL memory \(p. 839\)](#)
- [Aurora MySQL processes \(p. 839\)](#)

Aurora MySQL wait events

A *wait event* indicates a resource for which a session is waiting. For example, the wait event `io/socket/sql/client_connection` indicates that a thread is in the process of handling a new connection. Typical resources that a session waits for include the following:

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

A wait event doesn't by itself show a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

Large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now runs for hours, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

Aurora MySQL thread states

A *general thread state* is a `State` value that is associated with general query processing. For example, the `sending_data` indicates that a thread is reading and filtering rows for a query to determine the correct result set.

You can use thread states to tune Aurora MySQL in a similar fashion to how you use wait events. For example, frequent occurrences of `sending_data` usually indicate that a query isn't using an index. For more information about thread states, see [General Thread States](#) in the *MySQL Reference Manual*.

When you use Performance Insights, one of the following conditions is true:

- Performance Schema is turned on – Aurora MySQL shows wait events rather than the thread state.
- Performance Schema isn't turned on – Aurora MySQL shows the thread state.

We recommend that you configure the Performance Schema for automatic management. The Performance Schema provides additional insights and better tools to investigate potential performance problems. For more information, see [Enabling the Performance Schema for Performance Insights on Aurora MySQL \(p. 580\)](#).

Aurora MySQL memory

In Aurora MySQL, the most important memory areas are the buffer pool and log buffer.

Topics

- [Buffer pool \(p. 839\)](#)

Buffer pool

The *buffer pool* is the shared memory area where Aurora MySQL caches table and index data. Queries can access frequently used data directly from memory without reading from disk.

The buffer pool is structured as a linked list of pages. A *page* can hold multiple rows. Aurora MySQL uses a least recently used (LRU) algorithm to age pages out of the pool.

For more information, see [Buffer Pool](#) in the *MySQL Reference Manual*.

Aurora MySQL processes

Aurora MySQL uses a process model that is very different from Aurora PostgreSQL.

Topics

- [MySQL server \(mysqld\) \(p. 839\)](#)
- [Threads \(p. 840\)](#)
- [Thread pool \(p. 840\)](#)

MySQL server (mysqld)

The MySQL server is a single operating-system process named mysqld. The MySQL server doesn't spawn additional processes. Thus, an Aurora MySQL database uses mysqld to perform most of its work.

When the MySQL server starts, it listens for network connections from MySQL clients. When a client connects to the database, mysqld opens a thread.

Threads

Connection manager threads associate each client connection with a dedicated thread. This thread manages authentication, runs statements, and returns results to the client. Connection manager creates new threads when necessary.

The *thread cache* is the set of available threads. When a connection ends, MySQL returns the thread to the thread cache if the cache isn't full. The `thread_cache_size` system variable determines the thread cache size.

Thread pool

The *thread pool* consists of a number of thread groups. Each group manages a set of client connections. When a client connects to the database, the thread pool assigns the connections to thread groups in round-robin fashion. The thread pool separates connections and threads. There is no fixed relationship between connections and the threads that run statements received from those connections.

Tuning Aurora MySQL with wait events

The following table summarizes the Aurora MySQL wait events that most commonly indicate performance problems. The following wait events are a subset of the list in [Aurora MySQL wait events \(p. 1063\)](#).

Wait event	Description
cpu (p. 841)	This event occurs when a thread is active in CPU or is waiting for CPU.
io/aurora_redo_log_flush (p. 844)	This event occurs when a session is writing persistent data to Aurora storage.
io/aurora_respond_to_client (p. 847)	This event occurs when a thread is waiting to return a result set to a client.
io/file/innodb/innodb_data_file (p. 849)	This event occurs when there are threads waiting on I/O operations from storage.
io/socket/sql/client_connection (p. 851)	This event occurs when a thread is in the process of handling a new connection.
io/table/sql/handler (p. 853)	This event occurs when work has been delegated to a storage engine.
synch/cond/mysys/my_thread_var::suspend (p. 856)	This event occurs when threads are suspended because they are waiting on a condition.
synch/cond/sql/MDL_context::COND_wait_status (p. 857)	This event occurs when there are threads waiting on a table metadata lock.
synch/mutex/innodb/aurora_lock_thread_slot_futex (p. 864)	This event occurs when one session has locked a row for an update, and another session tries to update the same row.
synch/mutex/innodb/buf_pool_mutex (p. 866)	This event occurs when a thread has acquired a lock on the InnoDB buffer pool to access a page in memory.
synch/mutex/innodb/fil_system_mutex (p. 868)	This event occurs when a session is waiting to access the tablespace memory cache.

Wait event	Description
synch/mutex/innodb/trx_sys_mutex (p. 871)	This event occurs when there is high database activity with a large number of transactions.
synch/rwlock/innodb/hash_table_locks (p. 872)	This event occurs when there is contention on modifying the hash table that maps the buffer cache.
synch/sxlock/innodb/hash_table_locks (p. 874)	This event occurs when pages not found in the buffer pool must be read from a file.

cpu

The `cpu` wait event occurs when a thread is active in CPU or is waiting for CPU.

Topics

- [Supported engine versions \(p. 841\)](#)
- [Context \(p. 841\)](#)
- [Likely causes of increased waits \(p. 842\)](#)
- [Actions \(p. 842\)](#)

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1

Context

For every vCPU, a connection can run work on this CPU. In some situations, the number of active connections that are ready to run is higher than the number of vCPUs. This imbalance results in connections waiting for CPU resources. If the number of active connections stays consistently higher than the number of vCPUs, then your instance experiences CPU contention. The contention causes the `cpu` wait event to occur.

Note

The Performance Insights metric for CPU is `DBLoadCPU`. The value for `DBLoadCPU` can differ from the value for the CloudWatch metric `CPUUtilization`. The latter metric is collected from the HyperVisor for a database instance.

Performance Insights OS metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`
- `os.cpuUtilization.wait.avg`
- `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

Likely causes of increased waits

When this event occurs more than normal, possibly indicating a performance problem, typical causes include the following:

- Analytic queries
- Highly concurrent transactions
- Long-running transactions
- A sudden increase in the number of connections, known as a *login storm*
- An increase in context switching

Actions

If the `cpu` wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Depending on the cause of the increase in CPU utilization, consider the following strategies:

- Increase the CPU capacity of the host. This approach typically gives only temporary relief.
- Identify top queries for potential optimization.
- Redirect some read-only workload to reader nodes, if applicable.

Topics

- [Identify the sessions or queries that are causing the problem \(p. 842\)](#)
- [Analyze and optimize the high CPU workload \(p. 843\)](#)

Identify the sessions or queries that are causing the problem

To find the sessions and queries, look at the **Top SQL** table in Performance Insights for the SQL statements that have the highest CPU load. For more information, see [Analyzing metrics with the Performance Insights dashboard \(p. 585\)](#).

Typically, one or two SQL statements consume the majority of CPU cycles. Concentrate your efforts on these statements. Suppose that your DB instance has 2 vCPUs with a DB load of 3.1 average active sessions (AAS), all in the CPU state. In this case, your instance is CPU bound. Consider the following strategies:

- Upgrade to a larger instance class with more vCPUs.
- Tune your queries to have lower CPU load.

In this example, the top SQL queries have a DB load of 1.5 AAS, all in the CPU state. Another SQL statement has a load of 0.1 in the CPU state. In this example, if you stopped the lowest-load SQL statement, you don't significantly reduce database load. However, if you optimize the two high-load queries to be twice as efficient, you eliminate the CPU bottleneck. If you reduce the CPU load of 1.5 AAS by 50 percent, the AAS for each statement decreases to 0.75. The total DB load spent on CPU is now 1.6 AAS. This value is below the maximum vCPU line of 2.0.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#). Also see the AWS Support article [How can I troubleshoot and resolve high CPU utilization on my Amazon RDS for MySQL instances?](#).

Analyze and optimize the high CPU workload

After you identify the query or queries increasing CPU usage, you can either optimize them or end the connection. The following example shows how to end a connection.

```
CALL mysql.rds_kill(processID);
```

For more information, see [mysql.rds_kill](#) in the *Amazon RDS User Guide*.

If you end a session, the action might trigger a long rollback.

Follow the guidelines for optimizing queries

To optimize queries, consider the following guidelines:

- Run the `EXPLAIN` statement.

This command shows the individual steps involved in running a query. For more information, see [Optimizing Queries with EXPLAIN](#) in the MySQL documentation.

- Run the `SHOW PROFILE` statement.

Use this statement to review profile details that can indicate resource usage for statements that are run during the current session. For more information, see [SHOW PROFILE Statement](#) in the MySQL documentation.

- Run the `ANALYZE TABLE` statement.

Use this statement to refresh the index statistics for the tables accessed by the high-CPU consuming query. By analyzing the statement, you can help the optimizer choose an appropriate execution plan. For more information, see [ANALYZE TABLE Statement](#) in the MySQL documentation.

Follow the guidelines for improving CPU usage

To improve CPU usage in a database instance, follow these guidelines:

- Ensure that all queries are using proper indexes.
- Find out whether you can use Aurora parallel queries. You can use this technique to reduce CPU usage on the head node by pushing down function processing, row filtering, and column projection for the `WHERE` clause.
- Find out whether the number of SQL executions per second meets the expected thresholds.
- Find out whether index maintenance or new index creation takes up CPU cycles needed by your production workload. Schedule maintenance activities outside of peak activity times.
- Find out whether you can use partitioning to help reduce the query data set. For more information, see the blog post [How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads](#).

Check for connection storms

If the `DBLoadCPU` metric is not very high, but the `CPUUtilization` metric is high, the cause of the high CPU utilization lies outside of the database engine. A classic example is a connection storm.

Check whether the following conditions are true:

- There is an increase in both the Performance Insights `CPUUtilization` metric and the Amazon CloudWatch `DatabaseConnections` metric.

- The number of threads in the CPU is greater than the number of vCPUs.

If the preceding conditions are true, consider decreasing the number of database connections. For example, you can use a connection pool such as RDS Proxy. To learn the best practices for effective connection management and scaling, see the whitepaper [Amazon Aurora MySQL DBA Handbook for Connection Management](#).

io/aurora_redo_log_flush

The `io/aurora_redo_log_flush` event occurs when a session is writing persistent data to Amazon Aurora storage.

Topics

- [Supported engine versions \(p. 844\)](#)
- [Context \(p. 844\)](#)
- [Likely causes of increased waits \(p. 844\)](#)
- [Actions \(p. 845\)](#)

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2.x up to 2.09.2
- Aurora MySQL version 1.x up to 1.23.1

Context

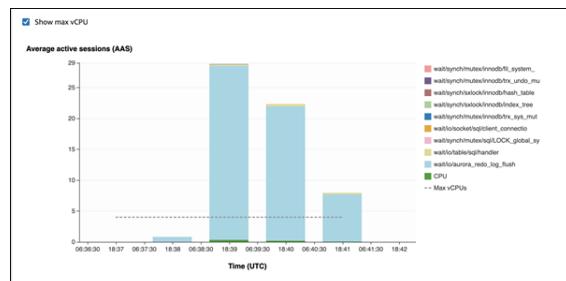

The `io/aurora_redo_log_flush` event is for a write input/output (I/O) operation in Aurora MySQL.

Likely causes of increased waits

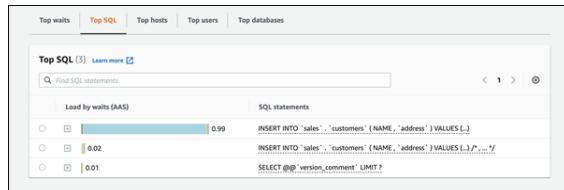

For data persistence, commits require a durable write to stable storage. If the database is doing too many commits, there is a wait event on the write I/O operation, the `io/aurora_redo_log_flush` wait event.

In the following examples, 50,000 records are inserted into an Aurora MySQL DB cluster using the db.r5.xlarge DB instance class:

- In the first example, each session inserts 10,000 records row by row. By default, if a data manipulation language (DML) command isn't within a transaction, Aurora MySQL uses implicit commits. Autocommit is turned on. This means that for each row insertion there is a commit. Performance Insights shows that the connections spend most of their time waiting on the `io/aurora_redo_log_flush` wait event.

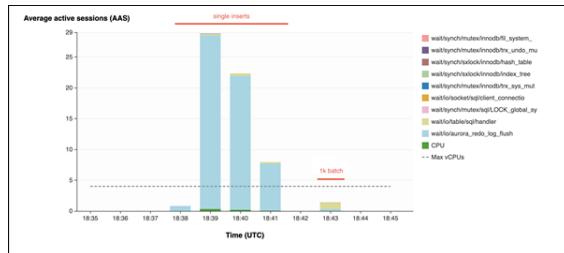

This is caused by the simple insert statements used.

The 50,000 records take 3.5 minutes to be inserted.

- In the second example, inserts are made in 1,000 batches, that is each connection performs 10 commits instead of 10,000. Performance Insights shows that the connections don't spend most of their time on the `io/aurora_redo_log_flush` wait event.

The 50,000 records take 4 seconds to be inserted.

Actions

We recommend different actions depending on the causes of your wait event.

Identify the problematic sessions and queries

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful AWS Database Blog post, see [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

To identify sessions and queries causing a bottleneck

- Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
- In the navigation pane, choose **Performance Insights**.
- Choose your DB instance.
- In **Database load**, choose **Slice by wait**.
- At the bottom of the page, choose **Top SQL**.

The queries at the top of the list are causing the highest load on the database.

Group your write operations

The following examples trigger the `io/aurora_redo_log_flush` wait event. (Autocommit is turned on.)

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
....
```

```

INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');

UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
....
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;

```

To reduce the time spent waiting on the `io/aurora_redo_log_flush` wait event, group your write operations logically into a single commit to reduce persistent calls to storage.

Turn off autocommit

Turn off autocommit before making large changes that aren't within a transaction, as shown in the following example.

```

SET SESSION AUTOCOMMIT=OFF;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
....
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
-- Other DML statements here
COMMIT;

SET SESSION AUTOCOMMIT=ON;

```

Use transactions

You can use transactions, as shown in the following example.

```

BEGIN
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');
....
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;

-- Other DML statements here
END

```

Use batches

You can make changes in batches, as shown in the following example. However, using batches that are too large can cause performance issues, especially in read replicas or when doing point-in-time recovery (PITR).

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES
```

```
('xxxx', 'xxxxx'), ('xxxx', 'xxxxx'), ..., ('xxxx', 'xxxxx'), ('xxxx', 'xxxxx');

UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1 BETWEEN xx AND xxx;

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1<xx;
```

io/aurora_respond_to_client

The `io/aurora_respond_to_client` event occurs when a thread is waiting to return a result set to a client.

Topics

- [Supported engine versions \(p. 847\)](#)
- [Context \(p. 847\)](#)
- [Likely causes of increased waits \(p. 847\)](#)
- [Actions \(p. 848\)](#)

Supported engine versions

This wait event information is supported for the following engine versions:

- For Aurora MySQL version 2, version 2.07.7 and higher 2.07 versions, 2.09.3 and higher 2.09 versions, and 2.10.2 and higher 2.10 versions
- For Aurora MySQL version 1, version 1.22.6 and higher

In versions before version 1.22.6, 2.07.7, 2.09.3, and 2.10.2, this wait event erroneously includes idle time.

Context

The event `io/aurora_respond_to_client` indicates that a thread is waiting to return a result set to a client.

The query processing is complete, and the results are being returned back to the application client. However, because there isn't enough network bandwidth on the DB cluster, a thread is waiting to return the result set.

Likely causes of increased waits

When the `io/aurora_respond_to_client` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

DB instance class insufficient for the workload

The DB instance class used by the DB cluster doesn't have the necessary network bandwidth to process the workload efficiently.

Large result sets

There was an increase in size of the result set being returned, because the query returns higher numbers of rows. The larger result set consumes more network bandwidth.

Increased load on the client

There might be CPU pressure, memory pressure, or network saturation on the client. An increase in load on the client delays the reception of data from the Aurora MySQL DB cluster.

Increased network latency

There might be increased network latency between the Aurora MySQL DB cluster and client. Higher network latency increases the time required for the client to receive the data.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- [Identify the sessions and queries causing the events \(p. 848\)](#)
- [Scale the DB instance class \(p. 848\)](#)
- [Check workload for unexpected results \(p. 848\)](#)
- [Distribute workload with reader instances \(p. 849\)](#)
- [Use the SQL_BUFFER_RESULT modifier \(p. 849\)](#)

Identify the sessions and queries causing the events

You can use Performance Insights to show queries blocked by the `io/aurora_respond_to_client` wait event. Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the AWS Database Blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

Scale the DB instance class

Check for the increase in the value of the Amazon CloudWatch metrics related to network throughput, such as `NetworkReceiveThroughput` and `NetworkTransmitThroughput`. If the DB instance class network bandwidth is being reached, you can scale the DB instance class used by the DB cluster by modifying the DB cluster. A DB instance class with larger network bandwidth returns data to clients more efficiently.

For information about monitoring Amazon CloudWatch metrics, see [Viewing metrics in the Amazon RDS console \(p. 563\)](#). For information about DB instance classes, see [Aurora DB instance classes \(p. 54\)](#). For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster \(p. 372\)](#).

Check workload for unexpected results

Check the workload on the DB cluster and make sure that it isn't producing unexpected results. For example, there might be queries that are returning a higher number of rows than expected. In this case,

you can use Performance Insights counter metrics such as `Innodb_rows_read`. For more information, see [Performance Insights counter metrics \(p. 653\)](#).

Distribute workload with reader instances

You can distribute read-only workload with Aurora replicas. You can scale horizontally by adding more Aurora replicas. Doing so can result in an increase in the throttling limits for network bandwidth. For more information, see [Amazon Aurora DB clusters \(p. 3\)](#).

Use the `SQL_BUFFER_RESULT` modifier

You can add the `SQL_BUFFER_RESULT` modifier to `SELECT` statements to force the result into a temporary table before they are returned to the client. This modifier can help with performance issues when InnoDB locks aren't being freed because queries are in the `io/aurora_respond_to_client` wait state. For more information, see [SELECT Statement](#) in the MySQL documentation.

io/file/innodb/innodb_data_file

The `io/file/innodb/innodb_data_file` event occurs when there are threads waiting on I/O operations from storage.

Topics

- [Supported engine versions \(p. 849\)](#)
- [Context \(p. 849\)](#)
- [Likely causes of increased waits \(p. 849\)](#)
- [Actions \(p. 850\)](#)

Supported engine versions

This wait event information is supported for the following engine versions:

Aurora MySQL version 1, up to 1.23.1

Context

The *InnoDB buffer pool* is the shared memory area where Aurora MySQL caches table and index data. Queries can access frequently used data directly from memory without reading from disk. The event `io/file/innodb/innodb_data_file` indicates that processing the query requires a storage I/O operation because the data isn't available in the buffer pool.

RDS typically generates this event when it performs I/O operations such as reads, writes, or flushes. RDS also generates this event when it runs data definition language (DDL) statements. This happens because these statements involve creating, deleting, opening, closing, or renaming InnoDB data files.

Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A spike in an application workload that's I/O intensive can increase the occurrence of this wait event because more queries need to read from storage.

A significant increase in the number of pages being scanned causes least recently used (LRU) pages to be evicted from the buffer pool at a faster rate. Inefficient query plans can contribute to the problem.

Query plans can be inefficient because of outdated states, missing indexes, or inefficiently written queries.

- Storage capacity is sufficient but network throughput exceeds the maximum bandwidth for the instance class, causing I/O throttling. For information about network throughput capacity for different instance classes, see [Hardware specifications for DB instance classes for Aurora \(p. 62\)](#).
- Operations involving DDL statements or transactions that read, insert, or modify a large number of rows. For example, bulk inserts or update or delete statements can specify a wide range of values in the `WHERE` clause.
- `SELECT` queries that scan a large number of rows. For example, queries that use `BETWEEN` or `IN` clauses can specify wide ranges of data.
- A low buffer pool hit ratio because the buffer pool is too small. The smaller the buffer pool, the more frequently LRU pages are flushed out. This increases the likelihood that the requested data is read from disk.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- [Identify and optimize problem queries \(p. 850\)](#)
- [Scale up your instance \(p. 850\)](#)
- [Make your buffer scan resistant \(p. 851\)](#)

Identify and optimize problem queries

Find the query digest responsible for this wait from Performance Insights. Check the query's statement execution plan to see if the query can be optimized to read fewer pages into the InnoDB buffer pool. Doing so reduces the number of least recently used pages that are evicted from the buffer pool. This increases the cache hit efficiency of the buffer pool, which lessens the load on the I/O subsystem.

To check a query's statement execution plan, run the `EXPLAIN` statement. This command shows the individual steps involved in query execution. For more information, see [Optimizing Queries with EXPLAIN](#) in the MySQL documentation.

Scale up your instance

If your `io/file/innodb/innodb_data_file` wait events are caused by insufficient network or buffer pool capacity, consider scaling up your RDS instance to a higher instance class type.

- Network throughput – Check for an increase in the value of the Amazon CloudWatch metrics `network receive throughput` and `network transmit throughput`. If your instance has reached the network bandwidth limit for your instance class, consider scaling up your RDS instance to a higher instance class type. For more information, see [Hardware specifications for DB instance classes for Aurora \(p. 62\)](#).
- Buffer pool size – Check for a low buffer pool hit ratio. To monitor this value in Performance Insights, check the `db.Cache.innoDB_buffer_pool_hit_rate.avg` metric. To add this metric, choose **Manage metrics**, and choose `innodb_buffer_pool_hit_rate` under **Cache** on the **Database metrics** tab.

If the hit ratio is low, consider scaling up your RDS instance to a higher instance class type.

Note

The DB instance parameter that controls the buffer pool size is `innodb_buffer_pool_size`. You can modify this parameter value, but we recommend that you scale up your instance class instead because the default value is optimized for each instance class.

Make your buffer scan resistant

If you have a mix of reporting and online transaction processing (OLTP) queries, consider making your buffer pool scan resistant. To do this, tune the parameters `innodb_old_blocks_pct` and `innodb_old_blocks_time`. The effects of these parameters can vary based on your instance class hardware, data, and workload type. We highly recommend that you benchmark your system before you set these parameters in your production environment. For more information, see [Making the Buffer Pool Scan Resistant](#) in the MySQL documentation.

io/socket/sql/client_connection

The `io/socket/sql/client_connection` event occurs when a thread is in the process of handling a new connection.

Topics

- [Supported engine versions \(p. 851\)](#)
- [Context \(p. 851\)](#)
- [Likely causes of increased waits \(p. 851\)](#)
- [Actions \(p. 851\)](#)

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1

Context

The event `io/socket/sql/client_connection` indicates that mysqld is busy creating threads to handle incoming new client connections. In this scenario, the processing of servicing new client connection requests slows down while connections wait for the thread to be assigned. For more information, see [MySQL server \(mysqld\) \(p. 839\)](#).

Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- There is a sudden increase in new user connections from the application to your Amazon RDS instance.
- Your DB instance can't process new connections because the network, CPU, or memory is being throttled.

Actions

If `io/socket/sql/client_connection` dominates database activity, it doesn't necessarily indicate a performance problem. In a database that isn't idle, a wait event is always on top. Act only when performance degrades. We recommend different actions depending on the causes of your wait event.

Topics

- [Identify the problematic sessions and queries \(p. 852\)](#)
- [Follow best practices for connection management \(p. 852\)](#)

- [Scale up your instance if resources are being throttled \(p. 852\)](#)
- [Check the top hosts and top users \(p. 853\)](#)
- [Query the performance_schema tables \(p. 853\)](#)
- [Check the thread states of your queries \(p. 853\)](#)
- [Audit your requests and queries \(p. 853\)](#)
- [Pool your database connections \(p. 853\)](#)

Identify the problematic sessions and queries

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful blog post, see [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

To identify sessions and queries causing a bottleneck

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose your DB instance.
4. In **Database load**, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The queries at the top of the list are causing the highest load on the database.

Follow best practices for connection management

To manage your connections, consider the following strategies:

- Use connection pooling.

You can gradually increase the number of connections as required. For more information, see the whitepaper [Amazon Aurora MySQL Database Administrator's Handbook](#).

- Use a reader node to redistribute read-only traffic.

For more information, see [Aurora Replicas \(p. 70\)](#) and [Amazon Aurora connection management \(p. 32\)](#).

Scale up your instance if resources are being throttled

Look for examples of throttling in the following resources:

- CPU

Check your Amazon CloudWatch metrics for high CPU usage.

- Network

Check for an increase in the value of the CloudWatch metrics `network_receive_throughput` and `network_transmit_throughput`. If your instance has reached the network bandwidth limit for your instance class, consider scaling up your RDS instance to a higher instance class type. For more information, see [Aurora DB instance classes \(p. 54\)](#).

- Freeable memory

Check for a drop in the CloudWatch metric `FreeableMemory`. Also, consider turning on Enhanced Monitoring. For more information, see [Monitoring OS metrics with Enhanced Monitoring \(p. 626\)](#).

Check the top hosts and top users

Use Performance Insights to check the top hosts and top users. For more information, see [Analyzing metrics with the Performance Insights dashboard \(p. 585\)](#).

Query the performance_schema tables

To get an accurate count of the current and total connections, query the `performance_schema` tables. With this technique, you identify the source user or host that is responsible for creating a high number of connections. For example, query the `performance_schema` tables as follows.

```
SELECT * FROM performance_schema.accounts;
SELECT * FROM performance_schema.users;
SELECT * FROM performance_schema.hosts;
```

Check the thread states of your queries

If your performance issue is ongoing, check the thread states of your queries. In the `mysql` client, issue the following command.

```
show processlist;
```

Audit your requests and queries

To check the nature of the requests and queries from user accounts, use Aurora MySQL Advanced Auditing. To learn how to turn on auditing, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster \(p. 914\)](#).

Pool your database connections

Consider using Amazon RDS Proxy for connection management. By using RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. For more information, see [Using Amazon RDS Proxy \(p. 288\)](#).

io/table/sql/handler

The `io/table/sql/handler` event occurs when work has been delegated to a storage engine.

Topics

- [Supported engine versions \(p. 853\)](#)
- [Context \(p. 854\)](#)
- [Likely causes of increased waits \(p. 854\)](#)
- [Actions \(p. 854\)](#)

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1

Context

The event `io/table` indicates a wait for access to a table. This event occurs regardless of whether the data is cached in the buffer pool or accessed on disk. The `io/table/sql/handler` event indicates an increase in workload activity.

A *handler* is a routine specialized in a certain type of data or focused on certain special tasks. For example, an event handler receives and digests events and signals from the operating system or from a user interface. A memory handler performs tasks related to memory. A file input handler is a function that receives file input and performs special tasks on the data, according to context.

Views such as `performance_schema.events_waits_current` often show `io/table/sql/handler` when the actual wait is a nested wait event such as a lock. When the actual wait isn't `io/table/sql/handler`, Performance Insights reports the nested wait event. When Performance Insights reports `io/table/sql/handler`, it represents the actual I/O wait and not a hidden nested wait event. For more information, see [Performance Schema Atom and Molecule Events](#) in the *MySQL Reference Manual*.

The `io/table/sql/handler` event often appears in top wait events with I/O waits such as `io/aurora_redo_log_flush` and `io/file/innodb/innodb_data_file`.

Likely causes of increased waits

In Performance Insights, sudden spikes in the `io/table/sql/handler` event indicate an increase in workload activity. Increased activity means increased I/O.

Performance Insights filters the nesting event IDs and doesn't report a `io/table/sql/handler` wait when the underlying nested event is a lock wait. For example, if the root cause event is `synch/mutex/innodb/aurora_lock_thread_slot_futex`, Performance Insights displays this wait in top wait events and not `io/table/sql/handler`.

In views such as `performance_schema.events_waits_current`, waits for `io/table/sql/handler` often appear when the actual wait is a nested wait event such as a lock. When the actual wait differs from `io/table/sql/handler`, Performance Insights looks up the nested wait and reports the actual wait instead of `io/table/sql/handler`. When Performance Insights reports `io/table/sql/handler`, the real wait is `io/table/sql/handler` and not a hidden nested wait event. For more information, see [Performance Schema Atom and Molecule Events](#) in the *MySQL 5.7 Reference Manual*.

Actions

If this wait event dominates database activity, it doesn't necessarily indicate a performance problem. A wait event is always on top when the database is active. You need to act only when performance degrades.

We recommend different actions depending on the other wait events that you see.

Topics

- [Identify the sessions and queries causing the events \(p. 854\)](#)
- [Check for a correlation with Performance Insights counter metrics \(p. 855\)](#)
- [Check for other correlated wait events \(p. 855\)](#)

[Identify the sessions and queries causing the events](#)

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance is isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

Check for a correlation with Performance Insights counter metrics

Check for Performance Insights counter metrics such as `Innodb_rows_changed`. If counter metrics are correlated with `io/table/sql/handler`, follow these steps:

1. In Performance Insights, look for the SQL statements accounting for the `io/table/sql/handler` top wait event. If possible, optimize this statement so that it returns fewer rows.
2. Retrieve the top tables from the `schema_table_statistics` and `x$schema_table_statistics` views. These views show the amount of time spent per table. For more information, see [The schema_table_statistics and x\\$schema_table_statistics Views](#) in the *MySQL Reference Manual*.

By default, rows are sorted by descending total wait time. Tables with the most contention appear first. The output indicates whether time is spent on reads, writes, fetches, inserts, updates, or deletes. The following example was run on an Aurora MySQL 2.09.1 instance.

```
mysql> select * from sys.schema_table_statistics limit 1\G
***** 1. row *****
    table_schema: read_only_db
      table_name: sbtest41
    total_latency: 54.11 m
      rows_fetched: 6001557
    fetch_latency: 39.14 m
      rows_inserted: 14833
    insert_latency: 5.78 m
      rows_updated: 30470
    update_latency: 5.39 m
      rows_deleted: 14833
    delete_latency: 3.81 m
  io_read_requests: NULL
    io_read: NULL
  io_read_latency: NULL
  io_write_requests: NULL
    io_write: NULL
  io_write_latency: NULL
  io_misc_requests: NULL
  io_misc_latency: NULL
1 row in set (0.11 sec)
```

Check for other correlated wait events

If `synch/sxlock/innodb/btr_search_latch` and `io/table/sql/handler` contribute most to the DB load anomaly together, check whether the `innodb_adaptive_hash_index` variable is turned on. If it is, consider increasing the `innodb_adaptive_hash_index_parts` parameter value.

If the Adaptive Hash Index is turned off, and the situation warrants it, consider turning it on. To learn more about the MySQL Adaptive Hash Index, see the following resources:

- The article [Is Adaptive Hash Index in InnoDB right for my workload?](#) on the Percona website
- [Adaptive Hash Index](#) in the *MySQL Reference Manual*
- The article [Contention in MySQL InnoDB: Useful Info From the Semaphores Section](#) on the Percona website

The Adaptive Hash Index isn't a viable option for Aurora reader nodes. In some cases, performance might be poor on a reader node when `synch/sxlock/innodb/btr_search_latch` and `io/table/sql/handler` are dominant. If so, consider redirecting the workload temporarily to the writer node and turning on the Adaptive Hash Index.

[synch/cond/mysys/my_thread_var::suspend](#)

The `synch/cond/mysys/my_thread_var::suspend` wait event indicates that threads are suspended because they are waiting on a condition.

Topics

- [Supported engine versions \(p. 856\)](#)
- [Context \(p. 856\)](#)
- [Likely causes of increased waits \(p. 856\)](#)
- [Actions \(p. 857\)](#)

[Supported engine versions](#)

This wait event information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2
- Aurora MySQL version 1 up to 1.23.1

[Context](#)

The event `synch/cond/mysys/my_thread_var::suspend` indicates that threads are suspended because they are waiting on a condition. For example, this wait event occurs when threads are waiting for a table-level lock. In this case, we recommend that you investigate your workload to determine which threads might be acquiring table locks on your DB instance.

[Likely causes of increased waits](#)

When the `synch/cond/mysys/my_thread_var::suspend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Thread waiting on a table-level lock

One or more threads are waiting on a table-level lock. In this case, the thread state is `Waiting for table level lock`.

Data being sent to the mysqldump client

One or more threads are waiting because you are using `mysqldump`, and the result is being sent to the `mysqldump` client. In this case, the thread state is `Writing to net`.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- [Avoid locking tables \(p. 857\)](#)
- [Make sure that backup tools don't lock tables \(p. 857\)](#)
- [Long-running sessions that lock tables \(p. 857\)](#)
- [Non-InnoDB temporary table \(p. 857\)](#)

Avoid locking tables

Make sure that the application is not explicitly locking the tables using the `LOCK TABLE` statement. You can check the statements run by applications using Advanced Auditing. For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster \(p. 914\)](#).

Make sure that backup tools don't lock tables

If you are using a backup tool, make sure that it isn't locking tables. For example, if you are using `mysqldump`, use the `--single-transaction` option so that it doesn't lock tables.

Long-running sessions that lock tables

There might be long-running sessions that have explicitly locked tables. Run the following SQL statement to check for such sessions.

```
SELECT
p.id as session_id, p.user, p.host, p.db, p.command, p.time, p.state,
SUBSTRING(p.info, 1, 50) AS INFO,
t trx_started, unix_timestamp(now()) - unix_timestamp(t trx_started) as trx_age_seconds,
t trx_rows_modified, t trx_isolation_level
FROM information_schema.processlist p
LEFT JOIN information_schema.innodb_trx t
ON p.id = t trx_mysql_thread_id;
```

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see [Ending a session or query](#) in the *Amazon RDS User Guide*.

For more information about identifying blocking transactions, see [Using InnoDB Transaction and Locking Information](#) in the MySQL documentation.

Non-InnoDB temporary table

If you are using a non-InnoDB temporary table, then the database doesn't use row-level locking, which can result in table locks. `MyISAM` and `MEMORY` tables are examples of a non-InnoDB temporary table. If you are using a non-InnoDB temporary table, consider switching to an InnoDB memory table.

synch/cond/sql/MDL_context::COND_wait_status

The `synch/cond/sql/MDL_context::COND_wait_status` event occurs when there are threads waiting on a table metadata lock.

Topics

- [Supported engine versions \(p. 858\)](#)
- [Context \(p. 858\)](#)
- [Likely causes of increased waits \(p. 858\)](#)
- [Actions \(p. 859\)](#)

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1

Context

The event `synch/cond/sql/MDL_context::COND_wait_status` indicates that there are threads waiting on a table metadata lock. In some cases, one session holds a metadata lock on a table and another session tries to get the same lock on the same table. In such a case, the second session waits on the `synch/cond/sql/MDL_context::COND_wait_status` wait event.

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies to tables, schemas, scheduled events, tablespaces, and user locks acquired with the `get_lock` function, and stored programs. Stored programs include procedures, functions, and triggers. For more information, see [Metadata locking](#) in the MySQL documentation.

The MySQL process list shows this session in the state `waiting for metadata lock`. In Performance Insights, if `Performance_schema` is turned on, the event `synch/cond/sql/MDL_context::COND_wait_status` appears.

The default timeout for a query waiting on a metadata lock is based on the value of the `lock_wait_timeout` parameter, which defaults to 31,536,000 seconds (365 days).

For more details on different InnoDB locks and the types of locks that can cause conflicts, see [InnoDB Locking](#) in the MySQL documentation.

Likely causes of increased waits

When the `synch/cond/sql/MDL_context::COND_wait_status` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Long-running transactions

One or more transactions are modifying a large amount of data and holding locks on tables for a very long time.

Idle transactions

One or more transactions remain open for a long time, without being committed or rolled back.

DDL statements on large tables

One or more data definition statements (DDL) statements, such as `ALTER TABLE` commands, were run on very large tables.

Explicit table locks

There are explicit locks on tables that aren't being released in a timely manner. For example, an application might run `LOCK TABLE` statements improperly.

Actions

We recommend different actions depending on the causes of your wait event and on the version of the Aurora MySQL DB cluster.

Topics

- [Identify the sessions and queries causing the events \(p. 859\)](#)
- [Check for past events \(p. 859\)](#)
- [Run queries on Aurora MySQL version 1 \(p. 860\)](#)
- [Run queries on Aurora MySQL version 2 \(p. 862\)](#)
- [Respond to the blocking session \(p. 864\)](#)

Identify the sessions and queries causing the events

You can use Performance Insights to show queries blocked by the `synch/cond/sql/MDI_context::COND_wait_status` wait event. However, to identify the blocking session, query metadata tables from `performance_schema` and `information_schema` on the DB cluster.

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard for that DB instance appears.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the AWS Database Blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

Check for past events

You can gain insight into this wait event to check for past occurrences of it. To do so, complete the following actions:

- Check the data manipulation language (DML) and DDL throughput and latency to see if there were any changes in workload.

You can use Performance Insights to find queries waiting on this event at the time of the issue. Also, you can view the digest of the queries run near the time of issue.

- If audit logs or general logs are turned on for the DB cluster, you can check for all queries run on the objects (schema.table) involved in the waiting transaction. You can also check for the queries that completed running before the transaction.

The information available to troubleshoot past events is limited. Performing these checks doesn't show which object is waiting for information. However, you can identify tables with heavy load at the time of

the event and the set of frequently operated rows causing conflict at the time of issue. You can then use this information to reproduce the issue in a test environment and provide insights about its cause.

Run queries on Aurora MySQL version 1

In Aurora MySQL version 1, you can query tables in `information_schema` and `performance_schema` to identify a blocking session. To run the queries, make sure that the DB cluster is configured with the `performance_schema consumer events_statements_history`. Also, maintain an adequate number of queries in `events_statements_history` table in `performance_schema`. You control the number of queries maintained in that table with the `performance_schema_events_statements_history_size` parameter. If the required data isn't available in `performance_schema`, you can check the audit logs or general logs.

An example can illustrate how to query tables to identify blocking queries and sessions. In this example, every session runs fewer than 10 statements and required consumers are enabled on the DB cluster.

In the following process list output, process ID 59 (running the `TRUNCATE` command) and process ID 53 (running the `INSERT` command) have been waiting on a metadata lock for 33 seconds. Also, both of the threads are running queries on same table named `sbtest.sbtest1`.

+-----+-----+-----+-----+
+-----+
3 rows in set (0.00 sec)

```

In the output, processes 40, 56, and 58 have been active for long time. Let's identify queries run by these sessions on the `sbtest.sbtest1` table.

```

MySQL [performance_schema]> select
      t.processlist_id,
      t.thread_id,
      sql_text
     from performance_schema.threads t
    join events_statements_history sh
      on t.thread_id=sh.thread_id
   where processlist_id in (40,56,58)
   and SQL_TEXT like '%sbtest1%' order by 1;
+-----+-----+-----+
| processlist_id | thread_id | sql_text          |
+-----+-----+-----+
|      56 |      84 | select * from sbtest123.sbtest10 limit 1 |
|      58 |      86 | select * from sbtest.sbtest1 limit 1      |
+-----+-----+-----+
2 rows in set (0.01 sec)

```

In this output, the session with a `processlist_id` of 58 ran a query on the table and holds an open transaction. That open transaction is blocking the `TRUNCATE` command.

Run queries on Aurora MySQL version 2

In Aurora MySQL version 2, you can identify the blocked session directly by querying `performance_schema` tables or `sys` schema views. An example can illustrate how to query tables to identify blocking queries and sessions.

In the following process list output, the connection ID 89 is waiting on a metadata lock, and it's running a `TRUNCATE TABLE` command. In a query on the `performance_schema` tables or `sys` schema views, the output shows that the blocking session is 76.

```

Respond to the blocking session

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see [Ending a session or query](#) in the *Amazon RDS User Guide*.

For more information about identifying blocking transactions, see [Using InnoDB Transaction and Locking Information](#) in the MySQL documentation.

[synch/mutex/innodb/aurora_lock_thread_slot_futex](#)

The `synch/mutex/innodb/aurora_lock_thread_slot_futex` event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see [InnoDB locking](#) in the *MySQL Reference*.

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1

Likely causes of increased waits

Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

Actions

We recommend different actions depending on the other wait events that you see.

Topics

- [Find and respond to the SQL statements responsible for this wait event \(p. 865\)](#)
- [Find and respond to the blocking session \(p. 865\)](#)

Find and respond to the SQL statements responsible for this wait event

Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:

- If row locks are a persistent problem, consider rewriting the application to use optimistic locking.
- Use multirow statements.
- Spread the workload over different database objects. One way to do achieve this is through partitioning.
- Check the value of the `innodb_lock_wait_timeout` parameter. It controls how long transactions wait before generating a timeout error.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

Find and respond to the blocking session

Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run `SHOW ENGINE INNODB STATUS`. The following example shows sample output.

```
mysql> SHOW ENGINE INNODB STATUS;
-----TRANSACTION 302631452, ACTIVE 2 sec starting index read
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 376, 1 row lock(s)
MySQL thread id 80109, OS thread handle 0x2ae915060700, query id 938819 10.0.4.12 reinvent
    updating
UPDATE sbtest1 SET k=k+1 WHERE id=503
----- TRX HAS BEEN WAITING 2 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 148 page no 11 n bits 30 index `PRIMARY` of table
`sysbench2`.`sbtest1` trx id 302631452 lock_mode X locks rec but not gap waiting
Record lock, heap no 30 PHYSICAL RECORD: n_fields 6; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```
mysql> SELECT p1.id waiting_thread,
        p1.user waiting_user,
        p1.host waiting_host,
        it1.trx_query waiting_query,
        ilw.requesting_trx_id waiting_transaction,
        ilw.blocking_lock_id blocking_lock,
        il.lock_mode blocking_mode,
        il.lock_type blocking_type,
        ilw.blocking_trx_id blocking_transaction,
        CASE it trx_state
            WHEN 'LOCK WAIT'
            THEN it trx_state
            ELSE p.state
        END blocker_state,
        il.lock_table locked_table,
        it.trx_mysql_thread_id blocker_thread,
```

```
        p.user blocker_user,
        p.host blocker_host
    FROM information_schema.innodb_lock_waits ilw
    JOIN information_schema.innodb_locks il
        ON ilw.blocking_lock_id = il.lock_id
        AND ilw.blocking_trx_id = il.lock_trx_id
    JOIN information_schema.innodb_trx it
        ON ilw.blocking_trx_id = it trx_id
    JOIN information_schema.processlist p
        ON it trx_mysql_thread_id = p.id
    JOIN information_schema.innodb_trx it1
        ON ilw.requesting_trx_id = it1 trx_id
    JOIN information_schema.processlist p1
        ON it1 trx_mysql_thread_id = p1.id\G

***** 1. row *****
waiting_thread: 3561959471
waiting_user: reinvent
waiting_host: 123.456.789.012:20485
waiting_query: select id1 from test.t1 where id1=1 for update
waiting_transaction: 312337314
blocking_lock: 312337287:261:3:2

```

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see [Ending a session or query](#) in the *Amazon RDS User Guide*.

For more information about identifying blocking transactions, see [Using InnoDB Transaction and Locking Information](#) in the *MySQL Reference Manual*.

synch/mutex/innodb/buf_pool_mutex

The `synch/mutex/innodb/buf_pool_mutex` event occurs when a thread has acquired a lock on the InnoDB buffer pool to access a page in memory.

Topics

- [Relevant engine versions \(p. 866\)](#)
- [Context \(p. 867\)](#)
- [Likely causes of increased waits \(p. 867\)](#)
- [Actions \(p. 867\)](#)

Relevant engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2.x up to 2.09.2

- Aurora MySQL version 1.x up to 1.23.1

Context

The `buf_pool` mutex is a single mutex that protects the control data structures of the buffer pool.

For more information, see [Monitoring InnoDB Mutex Waits Using Performance Schema](#) in the MySQL documentation.

Likely causes of increased waits

This is a workload-specific wait event. Common causes for `synch/mutex/innodb/buf_pool_mutex` to appear among the top wait events include the following:

- The buffer pool size isn't large enough to hold the working set of data.
- The workload is more specific to certain pages from a specific table in the database, leading to contention in the buffer pool.

Actions

We recommend different actions depending on the causes of your wait event.

Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To view the Top SQL chart in the AWS Management Console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. Underneath the **Database load** chart, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

Use Performance Insights

This event is related to workload. You can use Performance Insights to do the following:

- Identify when wait events start, and whether there's any change in the workload around that time from the application logs or related sources.
- Identify the SQL statements responsible for this wait event. Examine the execution plan of the queries to make sure that these queries are optimized and using appropriate indexes.

If the top queries responsible for the wait event are related to the same database object or table, then consider partitioning that object or table.

Create Aurora Replicas

You can create Aurora Replicas to serve read-only traffic. You can also use Aurora Auto Scaling to handle surges in read traffic. Make sure to run scheduled read-only tasks and logical backups on Aurora Replicas.

For more information, see [Using Amazon Aurora Auto Scaling with Aurora replicas \(p. 427\)](#).

Examine the buffer pool size

Check whether the buffer pool size is sufficient for the workload by looking at the metric `innodb_buffer_pool_wait_free`. If the value of this metric is high and increasing continuously, that indicates that the size of the buffer pool isn't sufficient to handle the workload. If `innodb_buffer_pool_size` has been set properly, the value of `innodb_buffer_pool_wait_free` should be small. For more information, see [Innodb_buffer_pool_wait_free](#) in the MySQL documentation.

Increase the buffer pool size if the DB instance has enough memory for session buffers and operating-system tasks. If it doesn't, change the DB instance to a larger DB instance class to get additional memory that can be allocated to the buffer pool.

Note

Aurora MySQL automatically adjusts the value of `innodb_buffer_pool_instances` based on the configured `innodb_buffer_pool_size`.

Monitor the global status history

By monitoring the change rates of status variables, you can detect locking or memory issues on your DB instance. Turn on Global Status History (GoSH) if it isn't already turned on. For more information on GoSH, see [Managing the global status history](#).

You can also create custom Amazon CloudWatch metrics to monitor status variables. For more information, see [Publishing custom metrics](#).

synch/mutex/innodb/fil_system_mutex

The `synch/mutex/innodb/fil_system_mutex` event occurs when a session is waiting to access the tablespace memory cache.

Topics

- [Supported engine versions \(p. 868\)](#)
- [Context \(p. 868\)](#)
- [Likely causes of increased waits \(p. 869\)](#)
- [Actions \(p. 869\)](#)

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1

Context

InnoDB uses tablespaces to manage the storage area for tables and log files. The *tablespace memory cache* is a global memory structure that maintains information about tablespaces. MySQL uses `synch`

`mutex/innodb/fil_system_mutex` waits to control concurrent access to the tablespace memory cache.

The event `synch/mutex/innodb/fil_system_mutex` indicates that there is currently more than one operation that needs to retrieve and manipulate information in the tablespace memory cache for the same tablespace.

Likely causes of increased waits

When the `synch/mutex/innodb/fil_system_mutex` event appears more than normal, possibly indicating a performance problem, this typically occurs when all of the following conditions are present:

- An increase in concurrent data manipulation language (DML) operations that update or delete data in the same table.
- The tablespace for this table is very large and has a lot of data pages.
- The fill factor for these data pages is low.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- [Identify the sessions and queries causing the events \(p. 869\)](#)
- [Reorganize large tables during off-peak hours \(p. 870\)](#)

Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard appears for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

Another way to find out which queries are causing high numbers of `synch/mutex/innodb/fil_system_mutex` waits is to check `performance_schema`, as in the following example.

```
mysql> select * from performance_schema.events_waits_current where EVENT_NAME='wait/synch/mutex/innodb/fil_system_mutex'\G
```

```
***** 1. row *****
    THREAD_ID: 19

```

Reorganize large tables during off-peak hours

Reorganize large tables that you identify as the source of high numbers of `synch/mutex/innodb/fil_system_mutex` wait events during a maintenance window outside of production hours. Doing so

ensures that the internal tablespaces map cleanup doesn't occur when quick access to the table is critical. For information about reorganizing tables, see [OPTIMIZE TABLE Statement](#) in the *MySQL Reference*.

synch/mutex/innodb/trx_sys_mutex

The `synch/mutex/innodb/trx_sys_mutex` event occurs when there is high database activity with a large number of transactions.

Topics

- [Relevant engine versions \(p. 871\)](#)
- [Context \(p. 871\)](#)
- [Likely causes of increased waits \(p. 871\)](#)
- [Actions \(p. 872\)](#)

Relevant engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2.x up to 2.09.2
- Aurora MySQL version 1.x up to 1.23.1

Context

Internally, the InnoDB database engine uses the repeatable read isolation level with snapshots to provide read consistency. This gives you a point-in-time view of the database at the time the snapshot was created.

In InnoDB, all changes are applied to the database as soon as they arrive, regardless of whether they're committed. This approach means that without multiversion concurrency control (MVCC), all users connected to the database see all of the changes and the latest rows. Therefore, InnoDB requires a way to track the changes to understand what to roll back when necessary.

To do this, InnoDB uses a transaction system (`trx_sys`) to track snapshots. The transaction system does the following:

- Tracks the transaction ID for each row in the undo logs.
- Uses an internal InnoDB structure called `ReadView` that helps to identify which transaction IDs are visible for a snapshot.

Likely causes of increased waits

Any database operation that requires the consistent and controlled handling (creating, reading, updating, and deleting) of transactions IDs generates a call from `trx_sys` to the mutex.

These calls happen inside three functions:

- `trx_sys_mutex_enter` – Creates the mutex.
- `trx_sys_mutex_exit` – Releases the mutex.
- `trx_sys_mutex_own` – Tests whether the mutex is owned.

The InnoDB Performance Schema instrumentation tracks all `trx_sys` mutex calls. Tracking includes, but isn't limited to, management of `trx_sys` on database startup or shutdown, rollback operations,

undo cleanups, row read access, and buffer pool loads. High database activity with a large number of transactions results in `synch/mutex/innodb/trx_sys_mutex` appearing among the top wait events.

For more information, see [Monitoring InnoDB Mutex Waits Using Performance Schema](#) in the MySQL documentation.

Actions

We recommend different actions depending on the causes of your wait event.

Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load. Find out whether you can optimize the database and application to reduce those events.

To view the Top SQL chart in the AWS Management Console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. Under the **Database load** chart, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

Examine other wait events

Examine the other wait events associated with the `synch/rwlock/innodb/hash_table_locks` wait event. Doing this can provide more information about the nature of the workload. A large number of transactions might reduce throughput, but the workload might also make this necessary.

For more information on how to optimize transactions, see [Optimizing InnoDB Transaction Management](#) in the MySQL documentation.

`synch/rwlock/innodb/hash_table_locks`

The `synch/rwlock/innodb/hash_table_locks` event occurs when there is contention on modifying the hash table that maps the buffer cache.

Topics

- [Supported engine versions \(p. 872\)](#)
- [Context \(p. 873\)](#)
- [Likely causes of increased waits \(p. 873\)](#)
- [Actions \(p. 873\)](#)

Supported engine versions

This wait event information is supported for Aurora MySQL version 1, up to 1.23.1.

Context

The event `synch/rwlock/innodb/hash_table_locks` indicates that there is contention on modifying the hash table that maps the buffer cache. A *hash table* is a table in memory designed to improve buffer pool access performance. This wait event is invoked when the hash table needs to be modified.

For more information, see [Buffer Pool](#) in the MySQL documentation.

Likely causes of increased waits

When the `synch/rwlock/innodb/hash_table_locks` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

An undersized buffer pool

The size of the buffer pool is too small to keep all of the frequently accessed pages in memory.

Heavy workload

The workload is causing frequent evictions and data pages reloads in the buffer cache.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- [Increase the size of the buffer pool \(p. 873\)](#)
- [Improve data access patterns \(p. 873\)](#)
- [Find SQL queries responsible for high load \(p. 873\)](#)
- [Reduce or avoid full-table scans \(p. 874\)](#)

Increase the size of the buffer pool

Make sure that the buffer pool is appropriately sized for the workload. To do so, you can check the buffer pool cache hit rate. Typically, if the value drops below 95 percent, consider increasing the buffer pool size. A larger buffer pool can keep frequently accessed pages in memory longer.

To increase the size of the buffer pool, modify the value of the `innodb_buffer_pool_size` parameter. The default value of this parameter is based on the DB instance class size. For more information, see the AWS Database Blog post [Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance](#).

Improve data access patterns

Check the queries affected by this wait and their execution plans. Consider improving data access patterns. For example, if you are using `mysql_result::fetch_array`, you can try increasing the array fetch size.

You can use Performance Insights to show queries and sessions that might be causing the `synch/rwlock/innodb/hash_table_locks` wait event.

Find SQL queries responsible for high load

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database

is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the AWS Database Blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

Reduce or avoid full-table scans

Monitor your workload to see if it's running full-table scans, and, if it is, reduce or avoid them. For example, you can monitor status variables such as `Handler_read_rnd_next`. For more information, see [Server Status Variables](#) in the MySQL documentation.

[synch/sxlock/innodb/hash_table_locks](#)

The `synch/sxlock/innodb/hash_table_locks` event occurs when pages not found in the buffer pool must be read from a file.

Topics

- [Supported engine versions \(p. 874\)](#)
- [Context \(p. 874\)](#)
- [Likely causes of increased waits \(p. 875\)](#)
- [Actions \(p. 875\)](#)

[Supported engine versions](#)

This wait event information is supported for Aurora MySQL version 2, up to 2.09.2.

[Context](#)

The event `synch/sxlock/innodb/hash_table_locks` indicates that a workload is frequently accessing data that isn't stored in the buffer pool. This wait event is associated with new page additions and old data evictions from the buffer pool. The data stored in the buffer pool aged and new data must be cached, so the aged pages are evicted to allow caching of the new pages. MySQL uses a least recently used (LRU) algorithm to evict pages from the buffer pool. The workload is trying to access data that hasn't been loaded into the buffer pool or data that has been evicted from the buffer pool.

This wait event occurs when the workload must access the data in files on disk or when blocks are freed from or added to the buffer pool's LRU list. These operations wait to obtain a shared excluded lock (SX-lock). This SX-lock is used for the synchronization over the *hash table*, which is a table in memory designed to improve buffer pool access performance.

For more information, see [Buffer Pool](#) in the MySQL documentation.

Likely causes of increased waits

When the `synch/sxlock/innodb/hash_table_locks` wait event appears more than normal, possibly indicating a performance problem, typical causes include the following:

An undersized buffer pool

The size of the buffer pool is too small to keep all of the frequently accessed pages in memory.

Heavy workload

The workload is causing frequent evictions and data pages reloads in the buffer cache.

Errors reading the pages

There are errors reading pages in the buffer pool, which might indicate data corruption.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- [Increase the size of the buffer pool \(p. 875\)](#)
- [Improve data access patterns \(p. 875\)](#)
- [Reduce or avoid full-table scans \(p. 876\)](#)
- [Check the error logs for page corruption \(p. 876\)](#)

Increase the size of the buffer pool

Make sure that the buffer pool is appropriately sized for the workload. To do so, you can check the buffer pool cache hit rate. Typically, if the value drops below 95 percent, consider increasing the buffer pool size. A larger buffer pool can keep frequently accessed pages in memory longer. To increase the size of the buffer pool, modify the value of the `innodb_buffer_pool_size` parameter. The default value of this parameter is based on the DB instance class size. For more information, see [Best practices for Amazon Aurora MySQL database configuration](#).

Improve data access patterns

Check the queries affected by this wait and their execution plans. Consider improving data access patterns. For example, if you are using `mysqli_result::fetch_array`, you can try increasing the array fetch size.

You can use Performance Insights to show queries and sessions that might be causing the `synch/sxlock/innodb/hash_table_locks` wait event.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.

- At the bottom of the page, choose **Top SQL**.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the AWS Database Blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).

Reduce or avoid full-table scans

Monitor your workload to see if it's running full-table scans, and, if it is, reduce or avoid them. For example, you can monitor status variables such as `Handler_read_rnd_next`. For more information, see [Server Status Variables](#) in the MySQL documentation.

Check the error logs for page corruption

You can check the `mysql-error.log` for corruption-related messages that were detected near the time of the issue. Messages that you can work with to resolve the issue are in the error log. You might need to recreate objects that were reported as corrupted.

Tuning Aurora MySQL with thread states

The following table summarizes the most common general thread states for Aurora MySQL.

General thread state	Description
??? (p. 876)	This thread state indicates that a thread is processing a <code>SELECT</code> statement that requires the use of an internal temporary table to sort the data.
??? (p. 879)	This thread state indicates that a thread is reading and filtering rows for a query to determine the correct result set.

creating sort index

The `creating sort index` thread state indicates that a thread is processing a `SELECT` statement that requires the use of an internal temporary table to sort the data.

Topics

- [Supported engine versions \(p. 876\)](#)
- [Context \(p. 877\)](#)
- [Likely causes of increased waits \(p. 877\)](#)
- [Actions \(p. 877\)](#)

Supported engine versions

This thread state information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2
- Aurora MySQL version 1 up to 1.23.1

Context

The `creating sort index` state appears when a query with an `ORDER BY` or `GROUP BY` clause can't use an existing index to perform the operation. In this case, MySQL needs to perform a more expensive `filesort` operation. This operation is typically performed in memory if the result set isn't too large. Otherwise, it involves creating a file on disk.

Likely causes of increased waits

The appearance of `creating sort index` doesn't by itself indicate a problem. If performance is poor, and you see frequent instances of `creating sort index`, the most likely cause is slow queries with `ORDER BY` or `GROUP BY` operators.

Actions

The general guideline is to find queries with `ORDER BY` or `GROUP BY` clauses that are associated with the increases in the `creating sort index` state. Then see whether adding an index or increasing the sort buffer size solves the problem.

Topics

- [Turn on the Performance Schema if it isn't turned on \(p. 877\)](#)
- [Identify the problem queries \(p. 877\)](#)
- [Examine the explain plans for filesort usage \(p. 877\)](#)
- [Increase the sort buffer size \(p. 878\)](#)

Turn on the Performance Schema if it isn't turned on

Performance Insights reports thread states only if Performance Schema instruments aren't turned on. When Performance Schema instruments are turned on, Performance Insights reports wait events instead. Performance Schema instruments provide additional insights and better tools when you investigate potential performance problems. Therefore, we recommend that you turn on the Performance Schema. For more information, see [Enabling the Performance Schema for Performance Insights on Aurora MySQL \(p. 580\)](#).

Identify the problem queries

To identify current queries that are causing increases in the `creating sort index` state, run `show processlist` and see if any of the queries have `ORDER BY` or `GROUP BY`. Optionally, run `explain` for connection `N`, where `N` is the process list ID of the query with `filesort`.

To identify past queries that are causing these increases, turn on the slow query log and find the queries with `ORDER BY`. Run `EXPLAIN` on the slow queries and look for "using filesort." For more information, see [Examine the explain plans for filesort usage \(p. 877\)](#).

Examine the explain plans for filesort usage

Identify the statements with `ORDER BY` or `GROUP BY` clauses that result in the `creating sort index` state.

The following example shows how to run `explain` on a query. The `Extra` column shows that this query uses `filesort`.

```
mysql> explain select * from mytable order by c1 limit 10\G
***** 1. row *****
```

```

      id: 1
select_type: SIMPLE
      table: mytable
    partitions: NULL
        type: ALL
possible_keys: NULL
          key: NULL
     key_len: NULL
        ref: NULL
      rows: 2064548
  filtered: 100.00
    Extra: Using filesort
1 row in set, 1 warning (0.01 sec)

```

The following example shows the result of running `EXPLAIN` on the same query after an index is created on column `c1`.

```
mysql> alter table mytable add index (c1);
```

```

mysql> explain select * from mytable order by c1 limit 10\G
***** 1. row ****
      id: 1
select_type: SIMPLE
      table: mytable
    partitions: NULL
        type: index
possible_keys: NULL
          key: c1
     key_len: 1023
        ref: NULL
      rows: 10
  filtered: 100.00
    Extra: Using index
1 row in set, 1 warning (0.01 sec)

```

For information on using indexes for sort order optimization, see [ORDER BY Optimization](#) in the MySQL documentation.

Increase the sort buffer size

To see whether a specific query required a `filesort` process that created a file on disk, check the `sort_merge_passes` variable value after running the query. The following shows an example.

```

mysql> show session status like 'sort_merge_passes';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Sort_merge_passes | 0 |
+-----+-----+
1 row in set (0.01 sec)

--- run query
mysql> select * from mytable order by u limit 10;
--- run status again:

mysql> show session status like 'sort_merge_passes';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Sort_merge_passes | 0 |
+-----+-----+

```

```
1 row in set (0.01 sec)
```

If the value of `sort_merge_passes` is high, consider increasing the sort buffer size. Apply the increase at the session level, because increasing it globally can significantly increase the amount of RAM MySQL uses. The following example shows how to change the sort buffer size before running a query.

```
mysql> set session sort_buffer_size=10*1024*1024;
Query OK, 0 rows affected (0.00 sec)
-- run query
```

sending data

The `sending data` thread state indicates that a thread is reading and filtering rows for a query to determine the correct result set. The name is misleading because it implies the state is transferring data, not collecting and preparing data to be sent later.

Topics

- [Supported engine versions \(p. 879\)](#)
- [Context \(p. 879\)](#)
- [Likely causes of increased waits \(p. 879\)](#)
- [Actions \(p. 880\)](#)

Supported engine versions

This thread state information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2
- Aurora MySQL version 1 up to 1.23.1

Context

Many thread states are short-lasting. Operations occurring during `sending data` tend to perform large numbers of disk or cache reads. Therefore, `sending data` is often the longest-running state over the lifetime of a given query. This state appears when Aurora MySQL is doing the following:

- Reading and processing rows for a `SELECT` statement
- Performing a large number of reads from either disk or memory
- Completing a full read of all data from a specific query
- Reading data from a table, an index, or the work of a stored procedure
- Sorting, grouping, or ordering data

After the `sending data` state finishes preparing the data, the thread state `writing to net` indicates the return of data to the client. Typically, `writing to net` is captured only when the result set is very large or severe network latency is slowing the transfer.

Likely causes of increased waits

The appearance of `sending data` doesn't by itself indicate a problem. If performance is poor, and you see frequent instances of `sending data`, the most likely causes are as follows.

Topics

- [Inefficient query \(p. 880\)](#)
- [Suboptimal server configuration \(p. 880\)](#)

Inefficient query

In most cases, what's responsible for this state is a query that isn't using an appropriate index to find the result set of a specific query. For example, consider a query reading a 10 million record table for all orders placed in California, where the state column isn't indexed or is poorly indexed. In the latter case, the index might exist, but the optimizer ignores it because of low cardinality.

Suboptimal server configuration

If several queries appear in the sending data state, the database server might be configured poorly. Specifically, the server might have the following issues:

- The database server doesn't have enough computing capacity: disk I/O, disk type and speed, CPU, or number of CPUs.
- The server is starved for allocated resources, such as the InnoDB buffer pool for InnoDB tables or the key buffer for MyISAM tables.
- Per-thread memory settings such as `sort_buffer`, `read_buffer`, and `join_buffer` consume more RAM than required, starving the physical server for memory resources.

Actions

The general guideline is to find queries that return large numbers of rows by checking the Performance Schema. If logging queries that don't use indexes is turned on, you can also examine the results from the slow logs.

Topics

- [Turn on the Performance Schema if it isn't turned on \(p. 880\)](#)
- [Examine memory settings \(p. 880\)](#)
- [Examine the explain plans for index usage \(p. 881\)](#)
- [Check the volume of data returned \(p. 881\)](#)
- [Check for concurrency issues \(p. 881\)](#)
- [Check the structure of your queries \(p. 881\)](#)

Turn on the Performance Schema if it isn't turned on

Performance Insights reports thread states only if Performance Schema instruments aren't turned on. When Performance Schema instruments are turned on, Performance Insights reports wait events instead. Performance Schema instruments provide additional insights and better tools when you investigate potential performance problems. Therefore, we recommend that you turn on the Performance Schema. For more information, see [Enabling the Performance Schema for Performance Insights on Aurora MySQL \(p. 580\)](#).

Examine memory settings

Examine the memory settings for the primary buffer pools. Make sure that these pools are appropriately sized for the workload. If your database uses multiple buffer pool instances, make sure that they aren't divided into many small buffer pools. Threads can only use one buffer pool at a time.

Make sure that the following memory settings used for each thread are properly sized:

- `read_buffer`
- `read_rnd_buffer`
- `sort_buffer`
- `join_buffer`
- `binlog_cache`

Unless you have a specific reason to modify the settings, use the default values.

Examine the explain plans for index usage

For queries in the sending `data` thread state, examine the plan to determine whether appropriate indexes are used. If a query isn't using a useful index, consider adding hints like `USE INDEX` or `FORCE INDEX`. Hints can greatly increase or decrease the time it takes to run a query, so use care before adding them.

Check the volume of data returned

Check the tables that are being queried and the amount of data that they contain. Can any of this data be archived? In many cases, the cause of poor query execution times isn't the result of the query plan, but the volume of data to be processed. Many developers are very efficient in adding data to a database but seldom consider dataset life cycle in the design and development phases.

Look for queries that perform well in low-volume databases but perform poorly in your current system. Sometimes developers who design specific queries might not realize that these queries are returning 350,000 rows. The developers might have developed the queries in a lower-volume environment with smaller datasets than production environments have.

Check for concurrency issues

Check whether multiple queries of the same type are running at the same time. Some forms of queries run efficiently when they run alone. However, if similar forms of query run together, or in high volume, they can cause concurrency issues. Often, these issues are caused when the database uses temp tables to render results. A restrictive transaction isolation level can also cause concurrency issues.

If tables are read and written to concurrently, the database might be using locks. To help identify periods of poor performance, examine the use of databases through large-scale batch processes. To see recent locks and rollbacks, examine the output of the `SHOW ENGINE INNODB STATUS` command.

Check the structure of your queries

Check whether captured queries from these states use subqueries. This type of query often leads to poor performance because the database compiles the results internally and then substitutes them back into the query to render data. This process is an extra step for the database. In many cases, this step can cause poor performance in a highly concurrent loading condition.

Also check whether your queries use large numbers of `ORDER BY` and `GROUP BY` clauses. In such operations, often the database must first form the entire dataset in memory. Then it must order or group it in a specific manner before returning it to the client.

Working with parallel query for Amazon Aurora MySQL

Following, you can find a description of the parallel query performance optimization for Amazon Aurora MySQL-Compatible Edition. This feature uses a special processing path for certain data-intensive queries, taking advantage of the Aurora shared storage architecture. Parallel query works best with Aurora MySQL DB clusters that have tables with millions of rows and analytic queries that take minutes or hours to complete. For information about Aurora MySQL versions that support parallel query in an AWS Region, see [Aurora parallel queries \(p. 26\)](#).

Overview of parallel query for Aurora MySQL

Aurora MySQL parallel query is an optimization that parallelizes some of the I/O and computation involved in processing data-intensive queries. The work that is parallelized includes retrieving rows from storage, extracting column values, and determining which rows match the conditions in the `WHERE` clause and join clauses. This data-intensive work is delegated (in database optimization terms, *pushed down*) to multiple nodes in the Aurora distributed storage layer. Without parallel query, each query brings all the scanned data to a single node within the Aurora MySQL cluster (the head node) and performs all the query processing there.

Tip

The PostgreSQL database engine also has a feature that's also called "parallel query". That feature is unrelated to Aurora parallel query.

When the parallel query feature is turned on, the Aurora MySQL engine automatically determines when queries can benefit, without requiring SQL changes such as hints or table attributes. In the following sections, you can find an explanation of when parallel query is applied to a query. You can also find how to make sure that parallel query is applied where it provides the most benefit.

Note

The parallel query optimization provides the most benefit for long-running queries that take minutes or hours to complete. Aurora MySQL generally doesn't perform parallel query optimization for inexpensive queries. It also generally doesn't perform parallel query optimization if another optimization technique makes more sense, such as query caching, buffer pool caching, or index lookups. If you find that parallel query isn't being used when you expect it, see [Verifying which statements use parallel query \(p. 895\)](#).

Topics

- [Benefits \(p. 883\)](#)
- [Architecture \(p. 884\)](#)
- [Prerequisites \(p. 884\)](#)
- [Limitations \(p. 885\)](#)

Benefits

With parallel query, you can run data-intensive analytic queries on Aurora MySQL tables. In many cases, you can get an order-of-magnitude performance improvement over the traditional division of labor for query processing.

Benefits of parallel query include the following:

- Improved I/O performance, due to parallelizing physical read requests across multiple storage nodes.
- Reduced network traffic. Aurora doesn't transmit entire data pages from storage nodes to the head node and then filter out unnecessary rows and columns afterward. Instead, Aurora transmits compact tuples containing only the column values needed for the result set.

- Reduced CPU usage on the head node, due to pushing down function processing, row filtering, and column projection for the `WHERE` clause.
- Reduced memory pressure on the buffer pool. The pages processed by the parallel query aren't added to the buffer pool. This approach reduces the chance of a data-intensive scan evicting frequently used data from the buffer pool.
- Potentially reduced data duplication in your extract, transform, load (ETL) pipeline, by making it practical to perform long-running analytic queries on existing data.

Architecture

The parallel query feature uses the major architectural principles of Aurora MySQL: decoupling the database engine from the storage subsystem, and reducing network traffic by streamlining communication protocols. Aurora MySQL uses these techniques to speed up write-intensive operations such as redo log processing. Parallel query applies the same principles to read operations.

Note

The architecture of Aurora MySQL parallel query differs from that of similarly named features in other database systems. Aurora MySQL parallel query doesn't involve symmetric multiprocessing (SMP) and so doesn't depend on the CPU capacity of the database server. The parallel processing happens in the storage layer, independent of the Aurora MySQL server that serves as the query coordinator.

By default, without parallel query, the processing for an Aurora query involves transmitting raw data to a single node within the Aurora cluster (the *head node*). Aurora then performs all further processing for that query in a single thread on that single node. With parallel query, much of this I/O-intensive and CPU-intensive work is delegated to nodes in the storage layer. Only the compact rows of the result set are transmitted back to the head node, with rows already filtered, and column values already extracted and transformed. The performance benefit comes from the reduction in network traffic, reduction in CPU usage on the head node, and parallelizing the I/O across the storage nodes. The amount of parallel I/O, filtering, and projection is independent of the number of DB instances in the Aurora cluster that runs the query.

Prerequisites

To use all features of parallel query requires an Aurora MySQL DB cluster that's running version 1.23 or 2.09 and higher. If you already have a cluster that you want to use with parallel query, you can upgrade it to a compatible version and turn on parallel query afterward. In that case, make sure to follow the upgrade procedure in [Upgrade considerations for parallel query \(p. 893\)](#) because the configuration setting names and default values are different in these newer versions.

You can also use parallel query with certain older Aurora MySQL versions that are compatible with MySQL 5.6: 1.22.2, 1.20.1, 1.19.6, and 5.6.10a. The parallel query support for these older versions is only available in certain AWS Regions. Those older versions have additional limitations, as described following. Using parallel query with an older Aurora MySQL version also requires creating a dedicated DB cluster with a special engine mode parameter that can't be changed later. For those reasons, we recommend using parallel query with Aurora MySQL 1.23 or 2.09 and higher where practical.

The DB instances in your cluster must be using the `db.r*` instance classes.

Make sure that the hash join optimization is turned on for your cluster. The procedure to do so is different depending on whether your cluster is running an Aurora MySQL version higher or lower than 1.23 or 2.09. To learn how, see [Turning on hash join for parallel query clusters \(p. 892\)](#).

To customize parameters such as `aurora_parallel_query` and `aurora_disable_hash_join`, you must have a custom parameter group that you use with your cluster. You can specify these parameters individually for each DB instance by using a DB parameter group. However, we recommend that you

specify them in a DB cluster parameter group. That way, all DB instances in your cluster inherit the same settings for these parameters.

Limitations

The following limitations apply to the parallel query feature:

- You can't use parallel query with the db.t2 or db.t3 instance classes. This limitation applies even if you request parallel query using the `aurora_pq_force` SQL hint.
- Parallel query doesn't apply to tables using the COMPRESSED or REDUNDANT row formats. Use the COMPACT or DYNAMIC row formats for tables you plan to use with parallel query.
- Aurora uses a cost-based algorithm to determine whether to use the parallel query mechanism for each SQL statement. Using certain SQL constructs in a statement can prevent parallel query or make parallel query unlikely for that statement. For information about compatibility of SQL constructs with parallel query, see [How parallel query works with SQL constructs \(p. 901\)](#).
- Each Aurora DB instance can run only a certain number of parallel query sessions at one time. If a query has multiple parts that use parallel query, such as subqueries, joins, or UNION operators, those phases run in sequence. The statement only counts as a single parallel query session at any one time. You can monitor the number of active sessions using the [parallel query status variables \(p. 898\)](#). You can check the limit on concurrent sessions for a given DB instance by querying the status variable `Aurora_pq_max_concurrent_requests`.
- Parallel query is available in all AWS Regions that Aurora supports. For most AWS Regions, the minimum required Aurora MySQL version to use parallel query is 1.23 or 2.09. For more information, see [Aurora parallel queries \(p. 26\)](#).
- Aurora MySQL 1.22.2, 1.20.1, 1.19.6, and 5.6.10a only: Using parallel query with these older versions involves creating a new cluster, or restoring from an existing Aurora MySQL cluster snapshot.
- Aurora MySQL 1.22.2, 1.20.1, 1.19.6, and 5.6.10a only: Parallel query doesn't support AWS Identity and Access Management (IAM) database authentication.

Planning for a parallel query cluster

Planning for a DB cluster that has parallel query turned on requires making some choices. These include performing setup steps (either creating or restoring a full Aurora MySQL cluster) and deciding how broadly to turn on parallel query across your DB cluster.

Consider the following as part of planning:

- Which Aurora MySQL version do you plan to use for the cluster? Depending on your choice, you can use one of these ways to turn on parallel query for the cluster:

If you use Aurora MySQL that's compatible with MySQL 5.7, you must choose Aurora MySQL 2.09 or higher. In this case, you always create a provisioned cluster. Then you turn on parallel query using the `aurora_parallel_query` parameter. We recommend this choice if you are starting with Aurora parallel query for the first time.

If you use Aurora MySQL that's compatible with MySQL 5.6, you can choose version 1.23 or certain lower versions. With version 1.23 or higher, you create a provisioned cluster and then turn on parallel query using the `aurora_parallel_query` DB cluster parameter. With a version lower than 1.23, you choose the `parallelquery` engine mode when creating the cluster. In this case, parallel query is permanently turned on for the cluster. The `parallelquery` engine mode imposes limitations on interoperating with other kinds of Aurora MySQL clusters. If you have a choice, we recommend choosing version 1.23 or higher for Aurora MySQL with MySQL 5.6 compatibility.

If you have an existing Aurora MySQL cluster that's running version 1.23 or higher, or 2.09 or higher, you don't have to create a new cluster to use parallel query. You can associate your cluster, or

specific DB instances in the cluster, with a parameter group that has the `aurora_parallel_query` parameter turned on. By doing so, you can reduce the time and effort to set up the relevant data to use with parallel query.

- Plan for any large tables that you need to reorganize so that you can use parallel query when accessing them. You might need to create new versions of some large tables where parallel query is useful. For example, you might need to remove full-text search indexes. For details, see [Creating schema objects to take advantage of parallel query \(p. 895\)](#).

Checking Aurora MySQL version compatibility for parallel query

To check which Aurora MySQL versions are compatible with parallel query clusters, use the `describe-db-engine-versions` AWS CLI command and check the value of the `SupportsParallelQuery` field. The following code example shows how to check which combinations are available for parallel query clusters in a specified AWS Region. Make sure to specify the full `--query` parameter string on a single line.

```
aws rds describe-db-engine-versions --region us-east-1 --engine aurora --query '*[]|[? SupportsParallelQuery == `true`].[EngineVersion]' --output text

aws rds describe-db-engine-versions --region us-east-1 --engine aurora-mysql --query '*[]|[?SupportsParallelQuery == `true`].[EngineVersion]' --output text
```

The preceding commands produce output similar to the following. The output might vary depending on which Aurora MySQL versions are available in the specified AWS Region.

```
5.6.10a
5.6.mysql_aurora.1.19.0
5.6.mysql_aurora.1.19.1
5.6.mysql_aurora.1.19.2
5.6.mysql_aurora.1.19.3
5.6.mysql_aurora.1.19.3.1
5.6.mysql_aurora.1.19.3.90
5.6.mysql_aurora.1.19.4
5.6.mysql_aurora.1.19.4.1
5.6.mysql_aurora.1.19.4.2
5.6.mysql_aurora.1.19.4.3
5.6.mysql_aurora.1.19.4.4
5.6.mysql_aurora.1.19.4.5
5.6.mysql_aurora.1.19.5
5.6.mysql_aurora.1.19.5.90
5.6.mysql_aurora.1.19.6
5.6.mysql_aurora.1.20.1
5.6.mysql_aurora.1.22.0
5.6.mysql_aurora.1.22.2
5.6.mysql_aurora.1.23.0

5.7.mysql_aurora.2.09.0
```

After you start using parallel query with a cluster, you can monitor performance and remove obstacles to parallel query usage. For those instructions, see [Performance tuning for parallel query \(p. 894\)](#).

Creating a DB cluster that works with parallel query

To create an Aurora MySQL cluster with parallel query, add new instances to it, or perform other administrative operations, you use the same AWS Management Console and AWS CLI techniques that you do with other Aurora MySQL clusters. You can create a new cluster to work with parallel query. You can also create a DB cluster to work with parallel query by restoring from a snapshot of a MySQL-

compatible Aurora DB cluster. If you aren't familiar with the process for creating a new Aurora MySQL cluster, you can find background information and prerequisites in [Creating an Amazon Aurora DB cluster \(p. 125\)](#).

However, certain options are different:

- When you choose an Aurora MySQL engine version, we recommend that you choose the latest engine that is compatible with MySQL 5.7. Currently, Aurora MySQL 2.09 or higher, and certain Aurora MySQL versions that are compatible with MySQL 5.6 support parallel query. You have more flexibility to turn parallel query on and off, or use parallel query with existing clusters, if you use Aurora MySQL 1.23 or 2.09 and higher.
- Only for Aurora MySQL before version 1.23: When you create or restore the DB cluster, make sure to choose the **parallelquery** engine mode.

Whether you create a new cluster or restore from a snapshot, you use the same techniques to add new DB instances that you do with other Aurora MySQL clusters.

Creating a parallel query cluster using the console

You can create a new parallel query cluster with the console as described following.

To create a parallel query cluster with the AWS Management Console

1. Follow the general AWS Management Console procedure in [Creating an Amazon Aurora DB cluster \(p. 125\)](#).
2. On the **Select engine** screen, choose Aurora MySQL.

For **Engine version**, choose Aurora MySQL 2.09 or higher, or Aurora MySQL 1.23 or higher if practical. With those versions, you have the fewest limitations on parallel query usage. Those versions also have the most flexibility to turn parallel query on or off at any time.

If it isn't practical to use a recent Aurora MySQL version for this cluster, choose **Show versions that support the parallel query feature**. Doing so filters the **Version** menu to show only the specific Aurora MySQL versions that are compatible with parallel query.

3. (For older versions only) For **Capacity type**, choose **Provisioned with Aurora parallel query enabled**. The AWS Management Console only displays this choice when you select an Aurora MySQL version lower than 1.23. For Aurora MySQL 1.23 or 2.09 and higher, you don't need to make any special choice to make the cluster compatible with parallel query.
4. (For recent versions only) For **Additional configuration**, choose a parameter group that you created for **DB cluster parameter group**. Using such a custom parameter group is required for Aurora MySQL 1.23 or 2.09 or 3.1 and higher. In your DB cluster parameter group, specify the parameter settings `aurora_parallel_query=ON` and `aurora_disable_hash_join=OFF`. Doing so turns on parallel query for the cluster, and turns on the hash join optimization which works in combination with parallel query.

To verify that a new cluster can use parallel query

1. Create a cluster using the preceding technique.
2. (For Aurora MySQL version 2.09 and higher minor versions, or Aurora MySQL version 3) Check that the `aurora_parallel_query` configuration setting is true.

```
mysql> select @@aurora_parallel_query;
+-----+
| @@aurora_parallel_query |
+-----+
```

```
|           1 |
+-----+
```

3. (For Aurora MySQL version 2.09 and higher minor versions) Check that the `aurora_disable_hash_join` setting is false.

```
mysql> select @@aurora_disable_hash_join;
+-----+
| @@aurora_disable_hash_join |
+-----+
|          0 |
+-----+
```

4. (For older versions only) Check that the `aurora_pq_supported` configuration setting is true.

```
mysql> select @@aurora_pq_supported;
+-----+
| @@aurora_pq_supported |
+-----+
|          1 |
+-----+
```

5. With some large tables and data-intensive queries, check the query plans to confirm that some of your queries are using the parallel query optimization. To do so, follow the procedure in [Verifying which statements use parallel query \(p. 895\)](#).

Creating a parallel query cluster using the CLI

You can create a new parallel query cluster with the CLI as described following.

To create a parallel query cluster with the AWS CLI

1. (Optional) Check which Aurora MySQL versions are compatible with parallel query clusters. To do so, use the `describe-db-engine-versions` command and check the value of the `SupportsParallelQuery` field. For an example, see [Checking Aurora MySQL version compatibility for parallel query \(p. 886\)](#).
2. (Optional) Create a custom DB cluster parameter group with the settings `aurora_parallel_query=ON` and `aurora_disable_hash_join=OFF`. Use commands such as the following.

```
aws rds create-db-cluster-parameter-group --db-parameter-group-family aurora-mysql5.7
--db-cluster-parameter-group-name pq-enabled-57-compatible
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name pq-
enabled-57-compatible \
    --parameters
    ParameterName=aurora_parallel_query,ParameterValue=ON,ApplyMethod=pending-reboot
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name pq-
enabled-57-compatible \
    --parameters
    ParameterName=aurora_disable_hash_join,ParameterValue=OFF,ApplyMethod=pending-reboot
```

If you perform this step, specify the option `--db-cluster-parameter-group-name my_cluster_parameter_group` in the subsequent `create-db-cluster` statement. Substitute the name of your own parameter group. If you omit this step, you create the parameter group and associate it with the cluster later, as described in [Turning parallel query on and off \(p. 890\)](#).

3. Follow the general AWS CLI procedure in [Creating an Amazon Aurora DB cluster \(p. 125\)](#).
4. Specify the following set of options:

- For the `--engine` option, use `aurora` or `aurora-mysql`. These values produce parallel query clusters that are compatible with MySQL 5.6 or MySQL 5.7 respectively.
- The value to use for the `--engine-mode` parameter depends on the engine version that you choose.

For Aurora MySQL 1.23 or higher, or 2.09 or higher, specify `--engine-mode provisioned`. You can also omit the `--engine-mode` parameter, because `provisioned` is the default. In these versions, you can turn parallel query on or off for the default kind of Aurora MySQL clusters, instead of creating clusters dedicated to always using parallel query.

Before Aurora MySQL 1.23, for the `--engine-mode` option, use `parallelquery`. The `--engine-mode` parameter applies to the `create-db-cluster` operation. Then the engine mode of the cluster is used automatically by subsequent `create-db-instance` operations.

- For the `--db-cluster-parameter-group-name` option, specify the name of a DB cluster parameter group that you created and specified the parameter value `aurora_parallel_query=ON`. If you omit this option, you can create the cluster with a default parameter group and later modify it to use such a custom parameter group.
- For the `--engine-version` option, use an Aurora MySQL version that's compatible with parallel query. Use the procedure from [Planning for a parallel query cluster \(p. 885\)](#) to get a list of versions if necessary. If practical, use at least 1.23.0 or 2.09.0. These versions and all higher ones contain substantial enhancements to parallel query.

The following code example shows how. Substitute your own value for each of the environment variables such as `$CLUSTER_ID`.

```
aws rds create-db-cluster --db-cluster-identifier $CLUSTER_ID --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.09.0 \
--master-username $MASTER_USER_ID --master-user-password $MASTER_USER_PW \
--db-cluster-parameter-group-name $CUSTOM_CLUSTER_PARAM_GROUP

aws rds create-db-cluster --db-cluster-identifier $CLUSTER_ID
--engine aurora --engine-version 5.6.mysql_aurora.1.23.0 \
--master-username $MASTER_USER_ID --master-user-password $MASTER_USER_PW \
--db-cluster-parameter-group-name $CUSTOM_CLUSTER_PARAM_GROUP

aws rds create-db-instance --db-instance-identifier ${INSTANCE_ID}-1 \
--engine same_value_as_in_create_cluster_command \
--db-cluster-identifier $CLUSTER_ID --db-instance-class $INSTANCE_CLASS
```

5. Verify that a cluster you created or restored has the parallel query feature available.

For Aurora MySQL 1.23 and 2.09 or higher: Check that the `aurora_parallel_query` configuration setting exists. If this setting has the value 1, parallel query is ready for you to use. If this setting has the value 0, set it to 1 before you can use parallel query. Either way, the cluster is capable of performing parallel queries.

```
mysql> select @@aurora_parallel_query;
+-----+
| @@aurora_parallel_query |
+-----+
| 1 |
+-----+
```

Before Aurora MySQL 1.23: Check that the `aurora_pq_supported` configuration setting is true.

```
mysql> select @@aurora_pq_supported;
+-----+
| @@aurora_pq_supported |
+-----+
```

```
+-----+  
| 1 |  
+-----+
```

To restore a snapshot to a parallel query cluster with the AWS CLI

1. Check which Aurora MySQL versions are compatible with parallel query clusters. To do so, use the `describe-db-engine-versions` command and check the value of the `SupportsParallelQuery` field. For an example, see [Checking Aurora MySQL version compatibility for parallel query \(p. 886\)](#). Decide which version to use for the restored cluster. If practical, choose Aurora MySQL 2.09.0 or higher for a MySQL 5.7-compatible cluster, or 1.23.0 or higher for a MySQL 5.6-compatible cluster.
2. Locate an Aurora MySQL-compatible cluster snapshot.
3. Follow the general AWS CLI procedure in [Restoring from a DB cluster snapshot \(p. 497\)](#).
4. The value to use for the `--engine-mode` parameter depends on the engine version that you choose.

For Aurora MySQL 1.23 or higher, or 2.09 or higher, specify `--engine-mode provisioned`. You can also omit the `--engine-mode` parameter, because `provisioned` is the default. In these versions, you can turn parallel query on or off for your Aurora MySQL clusters, instead of creating clusters dedicated to always using parallel query.

Before Aurora MySQL 1.23, specify `--engine-mode parallelquery`. The `--engine-mode` parameter applies to the `create-db-cluster` operation. Then the engine mode of the cluster is used automatically by subsequent `create-db-instance` operations.

```
aws rds restore-db-cluster-from-snapshot \  
  --db-cluster-identifier mynewdbcluster \  
  --snapshot-identifier mydbclustersnapshot \  
  --engine aurora \  
  --engine-mode parallelquery
```

5. Verify that a cluster you created or restored has the parallel query feature available. Use the same verification procedure as in [Creating a parallel query cluster using the CLI \(p. 888\)](#).

Turning parallel query on and off

Note

When parallel query is turned on, Aurora MySQL determines whether to use it at runtime for each query. In the case of joins, unions, subqueries, and so on, Aurora MySQL determines whether to use parallel query at runtime for each query block. For details, see [Verifying which statements use parallel query \(p. 895\)](#) and [How parallel query works with SQL constructs \(p. 901\)](#).

Aurora MySQL 1.23 and 2.09 or higher

In Aurora MySQL 1.23 and 2.09 or higher, you can turn on and turn off parallel query dynamically at both the global and session level for a DB instance by using the `aurora_parallel_query` option. You can change the `aurora_parallel_query` setting in your DB cluster group to turn parallel query on or off by default.

```
mysql> select @@aurora_parallel_query;  
+-----+  
| @@aurora_parallel_query|  
+-----+
```

```
|           1 |
+-----+
```

To toggle the `aurora_parallel_query` parameter at the session level, use the standard methods to change a client configuration setting. For example, you can do so through the `mysql` command line or within a JDBC or ODBC application. The command on the standard MySQL client is `set session aurora_parallel_query = { 'ON' / 'OFF' }`. You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

You can permanently change the setting for the `aurora_parallel_query` parameter, either for a specific DB instance or for your whole cluster. If you specify the parameter value in a DB parameter group, that value only applies to specific DB instance in your cluster. If you specify the parameter value in a DB cluster parameter group, all DB instances in the cluster inherit the same setting. To toggle the `aurora_parallel_query` parameter, use the techniques for working with parameter groups, as described in [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#). Follow these steps:

1. Create a custom cluster parameter group (recommended) or a custom DB parameter group.
2. In this parameter group, update `parallel_query` to the value that you want.
3. Depending on whether you created a DB cluster parameter group or a DB parameter group, attach the parameter group to your Aurora cluster or to the specific DB instances where you plan to use the parallel query feature.

Tip

Because `aurora_parallel_query` is a dynamic parameter, you don't need to restart your cluster after changing this setting.

You can modify the parallel query parameter by using the [ModifyDBClusterParameterGroup](#) or [ModifyDBParameterGroup](#) API operation or the AWS Management Console.

Before Aurora MySQL 1.23

For these older versions, you can turn on and turn off parallel query dynamically at both the global and session level for a DB instance by using the `aurora_pq` option. On clusters where the parallel query feature is available, the parameter is turned on by default.

```
mysql> select @@aurora_pq;
+-----+
| @@aurora_pq |
+-----+
|          1 |
+-----+
```

To toggle the `aurora_pq` parameter at the session level, for example through the `mysql` command line or within a JDBC or ODBC application, use the standard methods to change a client configuration setting. For example, the command on the standard MySQL client is `set session aurora_pq = { 'ON' / 'OFF' }`. You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

To toggle the `aurora_pq` parameter permanently, use the techniques for working with parameter groups, as described in [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#). Follow these steps:

1. Create a custom cluster parameter group or DB instance parameter group. We recommend using a cluster parameter group, so that all DB instance in the cluster inherit the same settings.
2. In this parameter group, update `aurora_pq` to the value that you want.

3. Associate the custom cluster parameter group with the Aurora cluster where you plan to use the parallel query feature. Or, for a custom DB parameter group, associate it with one or more DB instances in the cluster.
4. Restart all the DB instances of the cluster.

You can modify the parallel query parameter by using the [ModifyDBClusterParameterGroup](#) or [ModifyDBParameterGroup](#) API operation or the AWS Management Console.

Note

When parallel query is turned on, Aurora MySQL determines whether to use it at runtime for each query. In the case of joins, unions, subqueries, and so on, Aurora MySQL determines whether to use parallel query at runtime for each query block. For details, see [Verifying which statements use parallel query \(p. 895\)](#) and [How parallel query works with SQL constructs \(p. 901\)](#).

Turning on hash join for parallel query clusters

Parallel query is typically used for the kinds of resource-intensive queries that benefit from the hash join optimization. Thus, it's helpful to ensure that hash joins are turned on for clusters where you plan to use parallel query.

- In Aurora MySQL version 3, the hash join optimization is turned on by default. You can turn it on and off by using the `block_nested_loop` flag of the `optimizer_switch` configuration setting. The `aurora_disable_hash_join` option isn't used.
- In Aurora MySQL 1.23 or 2.09 and higher minor versions, the parallel query and hash join settings are both turned off by default. When you turn on parallel query for such a cluster, turn on hash joins also. The simplest way to do so is to set the cluster configuration parameter `aurora_disable_hash_join=OFF`.
- For Aurora MySQL 5.6-compatible clusters before version 1.23, hash joins are always available in parallel query clusters. In this case, you don't need to take any action for the hash join feature. If you upgrade such clusters to a higher release of version 1 or version 2, you do need to turn on hash joins at that time.

For information about how to use hash joins effectively, see [Optimizing large Aurora MySQL join queries with hash joins \(p. 1038\)](#).

Turning on and turning off parallel query using the console

You can turn on or turn off parallel query at the DB instance level or the DB cluster level by working with parameter groups.

To turn on or turn off parallel query for a DB cluster with the AWS Management Console

1. Create a custom parameter group, as described in [Working with DB parameter groups and DB cluster parameter groups \(p. 339\)](#).
2. For Aurora MySQL 1.23 and 2.09 or higher: Update `aurora_parallel_query` to `1` (turned on) or `0` (turned off). For clusters where the parallel query feature is available, `aurora_parallel_query` is turned off by default.

For Aurora MySQL before 1.23: Update `aurora_pq` to `1` (turned on) or `0` (turned off). For clusters where the parallel query feature is available, `aurora_pq` is turned on by default.

3. If you use a custom cluster parameter group, attach it to the Aurora DB cluster where you plan to use the parallel query feature. If you use a custom DB parameter group, attach it to one or more DB instances in the cluster. We recommend using a cluster parameter group. Doing so makes sure that all DB instances in the cluster have the same settings for parallel query and associated features such as hash join.

Turning on and turning off parallel query using the CLI

You can modify the parallel query parameter by using the `modify-db-cluster-parameter-group` or `modify-db-parameter-group` command. Choose the appropriate command depending on whether you specify the value of `aurora_parallel_query` through a DB cluster parameter group or a DB parameter group.

To turn on or turn off parallel query for a DB cluster with the CLI

- Modify the parallel query parameter by using the `modify-db-cluster-parameter-group` command. Use a command such as the following. Substitute the appropriate name for your own custom parameter group. Substitute either ON or OFF for the `ParameterValue` portion of the `--parameters` option.

```
# Aurora MySQL 1.23 or 2.09 and higher:  
$ aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-  
name cluster_param_group_name \  
  --parameters  
    ParameterName=aurora_parallel_query,ParameterValue=ON,ApplyMethod=pending-reboot  
{  
  "DBClusterParameterGroupName": "cluster_param_group_name"  
}  
  
# Before Aurora MySQL 1.23:  
$ aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-  
name cluster_param_group_name \  
  --parameters ParameterName=aurora_pq,ParameterValue=ON,ApplyMethod=pending-reboot  
{  
  "DBClusterParameterGroupName": "cluster_param_group_name"  
}
```

You can also turn on or turn off parallel query at the session level, for example through the `mysql` command line or within a JDBC or ODBC application. To do so, use the standard methods to change a client configuration setting. For example, the command on the standard MySQL client is `set session aurora_parallel_query = { 'ON' / 'OFF' }` for Aurora MySQL 1.23 or 2.09 and higher. Before Aurora MySQL 1.23, the command is `set session aurora_pq = { 'ON' / 'OFF' }`.

You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

Upgrade considerations for parallel query

Depending on the original and destination versions when you upgrade a parallel query cluster, you might find enhancements in the types of queries that parallel query can optimize. You might also find that you don't need to specify a special engine mode parameter for parallel query. The following sections explain the considerations when you upgrade a cluster that has parallel query turned on.

Upgrading parallel query clusters to Aurora MySQL version 3

Several SQL statements, clauses, and data types have new or improved parallel query support starting in Aurora MySQL version 3. When you upgrade from a release that's earlier than version 3, check whether additional queries can benefit from parallel query optimizations. For information about these parallel query enhancements, see [Column data types \(p. 905\)](#), [Partitioned tables \(p. 905\)](#), and [Aggregate functions, GROUP BY clauses, and HAVING clauses \(p. 906\)](#).

If you are upgrading a parallel query cluster from Aurora MySQL 2.08 or lower, also learn about changes in how to turn on parallel query. To do so, read [Upgrading to Aurora MySQL 1.23 or 2.09 and higher \(p. 894\)](#).

In Aurora MySQL version 3, the hash join optimization is turned on by default. The `aurora_disable_hash_join` configuration option from earlier versions isn't used.

Upgrading to Aurora MySQL 1.23 or 2.09 and higher

In Aurora MySQL 1.23 or 2.09 and higher, parallel query works for provisioned clusters and doesn't require the `parallelquery` engine mode parameter. Thus, you don't need to create a new cluster or restore from an existing snapshot to use parallel query with these versions. You can use the upgrade procedures described in [Upgrading the minor version or patch level of an Aurora MySQL DB cluster \(p. 1088\)](#) to upgrade your cluster to such a version. You can upgrade an older cluster regardless of whether it was a parallel query cluster or a provisioned cluster. To reduce the number of choices in the **Engine version** menu, you can choose **Show versions that support the parallel query feature** to filter the entries in that menu. Then choose Aurora MySQL 1.23 or 2.09 and higher.

After you upgrade an earlier parallel query cluster to Aurora MySQL 1.23 or 2.09 and higher, you turn on parallel query in the upgraded cluster. Parallel query is turned off by default in these versions, and the procedure for enabling it is different. The hash join optimization is also turned off by default and must be turned on separately. Thus, make sure that you turn on these settings again after the upgrade. For instructions on doing so, see [Turning parallel query on and off \(p. 890\)](#) and [Turning on hash join for parallel query clusters \(p. 892\)](#).

In particular, you turn on parallel query by using the configuration parameters `aurora_parallel_query=ON` and `aurora_disable_hash_join=OFF` instead of `aurora_pq_supported` and `aurora_pq`. The `aurora_pq_supported` and `aurora_pq` parameters are deprecated in the newer Aurora MySQL versions.

In the upgraded cluster, the `EngineMode` attribute has the value `provisioned` instead of `parallelquery`. To check whether parallel query is available for a specified engine version, now you check the value of the `SupportsParallelQuery` field in the output of the `describe-db-engine-versions` AWS CLI command. In earlier Aurora MySQL versions, you checked for the presence of `parallelquery` in the `SupportedEngineModes` list.

After you upgrade to Aurora MySQL 1.23 or 2.09 and higher, you can take advantage of the following features. These features aren't available to parallel query clusters running older Aurora MySQL versions.

- Performance Insights. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora \(p. 573\)](#).
- Backtracking. For more information, see [Backtracking an Aurora DB cluster \(p. 816\)](#).
- Stopping and starting the cluster. For more information, see [Stopping and starting an Amazon Aurora DB cluster \(p. 368\)](#).

Performance tuning for parallel query

To manage the performance of a workload with parallel query, make sure that parallel query is used for the queries where this optimization helps the most.

To do so, you can do the following:

- Make sure that your biggest tables are compatible with parallel query. You might change table properties or recreate some tables so that queries for those tables can take advantage of the parallel query optimization. To learn how, see [Creating schema objects to take advantage of parallel query \(p. 895\)](#).
- Monitor which queries use parallel query. To learn how, see [Monitoring parallel query \(p. 898\)](#).
- Verify that parallel query is being used for the most data-intensive and long-running queries, and with the right level of concurrency for your workload. To learn how, see [Verifying which statements use parallel query \(p. 895\)](#).

- Fine-tune your SQL code to turn on parallel query to apply to the queries that you expect. To learn how, see [How parallel query works with SQL constructs \(p. 901\)](#).

Creating schema objects to take advantage of parallel query

Before you create or modify tables that you plan to use for parallel query, make sure to familiarize yourself with the requirements described in [Prerequisites \(p. 884\)](#) and [Limitations \(p. 885\)](#).

Because parallel query requires tables to use the `ROW_FORMAT=Compact` or `ROW_FORMAT=Dynamic` setting, check your Aurora configuration settings for any changes to the `INNODB_FILE_FORMAT` configuration option. Issue the `SHOW TABLE STATUS` statement to confirm the row format for all the tables in a database.

Before changing your schema to turn on parallel query to work with more tables, make sure to test. Your tests should confirm if parallel query results in a net increase in performance for those tables. Also, make sure that the schema requirements for parallel query are otherwise compatible with your goals.

For example, before switching from `ROW_FORMAT=Compressed` to `ROW_FORMAT=Compact` or `ROW_FORMAT=Dynamic`, test the performance of workloads for the original and new tables. Also, consider other potential effects such as increased data volume.

Verifying which statements use parallel query

In typical operation, you don't need to perform any special actions to take advantage of parallel query. After a query meets the essential requirements for parallel query, the query optimizer automatically decides whether to use parallel query for each specific query.

If you run experiments in a development or test environment, you might find that parallel query isn't used because your tables are too small in number of rows or overall data volume. The data for the table might also be entirely in the buffer pool, especially for tables that you created recently to perform experiments.

As you monitor or tune cluster performance, make sure to decide whether parallel query is being used in the appropriate contexts. You might adjust the database schema, settings, SQL queries, or even the cluster topology and application connection settings to take advantage of this feature.

To check if a query is using parallel query, check the query plan (also known as the "explain plan") by running the `EXPLAIN` statement. For examples of how SQL statements, clauses, and expressions affect `EXPLAIN` output for parallel query, see [How parallel query works with SQL constructs \(p. 901\)](#).

The following example demonstrates the difference between a traditional query plan and a parallel query plan. This explain plan is from Query 3 from the TPC-H benchmark. Many of the sample queries throughout this section use the tables from the TPC-H dataset. You can get the table definitions, queries, and the `dbgen` program that generates sample data from [the TPC-h website](#).

```
EXPLAIN SELECT l_orderkey,
    sum(l_extendedprice * (1 - l_discount)) AS revenue,
    o_orderdate,
    o_shippriority
FROM customer,
     orders,
     lineitem
WHERE c_mktsegment = 'AUTOMOBILE'
AND c_custkey = o_custkey
AND l_orderkey = o_orderkey
```

```

AND o_orderdate < date '1995-03-13'
AND l_shipdate > date '1995-03-13'
GROUP BY l_orderkey,
    o_orderdate,
    o_shipppriority
ORDER BY revenue DESC,
    o_orderdate LIMIT 10;

```

By default, the query might have a plan like the following. If you don't see hash join used in the query plan, make sure that optimization is turned on first.

id	select_type	table	partitions	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	customer	NULL	ALL	NULL	NULL	NULL	NULL	1480234	Using where; Using temporary; Using filesort
1	SIMPLE	orders	NULL	ALL	NULL	NULL	NULL	NULL	14875240	Using where; Using join buffer (Block Nested Loop)
1	SIMPLE	lineitem	NULL	ALL	NULL	NULL	NULL	NULL	59270573	Using where; Using join buffer (Block Nested Loop)

You can turn on hash join at the session level by issuing the following statement. Afterwards, try the EXPLAIN statement again.

```

# For Aurora MySQL version 3:
SET optimizer_switch='block_nested_loop=on';

# For Aurora MySQL version 2.09 and higher:
SET optimizer_switch='hash_join=on';

```

For information about how to use hash joins effectively, see [Optimizing large Aurora MySQL join queries with hash joins \(p. 1038\)](#).

With hash join turned on but parallel query turned off, the query might have a plan like the following, which uses hash join but not parallel query.

id	select_type	table	rows	Extra
1	SIMPLE	customer	5798330	Using where; Using index; Using temporary; Using filesort
1	SIMPLE	orders	154545408	Using where; Using join buffer (Hash Join Outer table orders)
1	SIMPLE	lineitem	606119300	Using where; Using join buffer (Hash Join Outer table lineitem)

After parallel query is turned on, two steps in this query plan can use the parallel query optimization, as shown under the Extra column in the EXPLAIN output. The I/O-intensive and CPU-intensive processing for those steps is pushed down to the storage layer.

```
+---+...
+-----+
+| id | ...| Extra
+-----+
+| 1 | ...| Using where; Using index; Using temporary; Using filesort
+| 1 | ...| Using where; Using join buffer (Hash Join Outer table orders); Using parallel query (4 columns, 1 filters, 1 exprs; 0 extra)
+| 1 | ...| Using where; Using join buffer (Hash Join Outer table lineitem); Using parallel query (4 columns, 1 filters, 1 exprs; 0 extra)
+-----+
+|
```

For information about how to interpret EXPLAIN output for a parallel query and the parts of SQL statements that parallel query can apply to, see [How parallel query works with SQL constructs \(p. 901\)](#).

The following example output shows the results of running the preceding query on a db.r4.2xlarge instance with a cold buffer pool. The query runs substantially faster when using parallel query.

Note

Because timings depend on many environmental factors, your results might be different. Always conduct your own performance tests to confirm the findings with your own environment, workload, and so on.

```
-- Without parallel query

p_size	int(11)	NO		NULL		
p_container	char(10)	NO		NULL		
p_retailprice	decimal(15, 2)	NO		NULL		
p_comment	varchar(23)	NO		NULL		
+-----+-----+-----+-----+-----+-----+-----+						

Experiment with your workload to get a sense of whether individual SQL statements can take advantage of parallel query. Then use the following monitoring techniques to help verify how often parallel query is used in real workloads over time. For real workloads, extra factors such as concurrency limits apply.

Monitoring parallel query

If your Aurora MySQL cluster uses parallel query, you might see an increase in `VolumeReadIOPS` values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

In addition to the Amazon CloudWatch metrics described in [Viewing metrics in the Amazon RDS console \(p. 563\)](#), Aurora provides other global status variables. You can use these global status variables to help monitor parallel query execution. They can give you insights into why the optimizer might use or not use parallel query in a given situation. To access these variables, you can use the [SHOW GLOBAL STATUS](#) command. You can also find these variables listed following.

A parallel query session isn't necessarily a one-to-one mapping with the queries performed by the database. For example, suppose that your query plan has two steps that use parallel query. In that case, the query involves two parallel sessions and the counters for requests attempted and requests successful are incremented by two.

When you experiment with parallel query by issuing `EXPLAIN` statements, expect to see increases in the counters designated as "not chosen" even though the queries aren't actually running. When you work with parallel query in production, you can check if the "not chosen" counters are increasing faster than you expect. At this point, you can adjust so that parallel query runs for the queries that you expect. To do so, you can change your cluster settings, query mix, DB instances where parallel query is turned on, and so on.

These counters are tracked at the DB instance level. When you connect to a different endpoint, you might see different metrics because each DB instance runs its own set of parallel queries. You might also see different metrics when the reader endpoint connects to a different DB instance for each session.

Name	Description
<code>Aurora_pq_request_attempted</code>	The number of parallel query sessions requested. This value might represent more than one session per query, depending on SQL constructs such as subqueries and joins.
<code>Aurora_pq_request_executed</code>	The number of parallel query sessions run successfully.
<code>Aurora_pq_request_failed</code>	The number of parallel query sessions that returned an error to the client. In some cases, a request for a parallel query might fail, for example due to a problem in the storage layer. In these cases, the query part that failed is retried using the nonparallel query mechanism. If the retried query also fails, an error is returned to the client and this counter is incremented.

<code>Aurora_pq_pages_pushed_down</code>	The number of data pages (each with a fixed size of 16 KiB) where parallel query avoided a network transmission to the head node.
<code>Aurora_pq_bytes_returned</code>	The number of bytes for the tuple data structures transmitted to the head node during parallel queries. Divide by 16,384 to compare against <code>Aurora_pq_pages_pushed_down</code> .
<code>Aurora_pq_request_not_chosen</code>	The number of times parallel query wasn't chosen to satisfy a query. This value is the sum of several other more granular counters. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
<code>Aurora_pq_request_not_chosen_below_min_rows</code>	The number of times parallel query wasn't chosen due to the number of rows in the table. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
<code>Aurora_pq_request_not_chosen_small_table</code>	The number of times parallel query wasn't chosen due to the overall size of the table, as determined by number of rows and average row length. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
<code>Aurora_pq_request_not_chosen_high_buffer_pool_pct</code>	The number of times parallel query wasn't chosen because a high percentage of the table data (currently, greater than 95 percent) was already in the buffer pool. In these cases, the optimizer determines that reading the data from the buffer pool is more efficient. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
<code>Aurora_pq_request_not_chosen_few_pages_outside_buffer_pool</code>	The number of times parallel query wasn't chosen, even though less than 95 percent of the table data was in the buffer pool, because there wasn't enough unbuffered table data to make parallel query worthwhile.
<code>Aurora_pq_max_concurrent_requests</code>	The maximum number of parallel query sessions that can run concurrently on this Aurora DB instance. This is a fixed number that depends on the AWS DB instance class.
<code>Aurora_pq_request_in_progress</code>	The number of parallel query sessions currently in progress. This number applies to the particular Aurora DB instance that you are connected to, not the entire Aurora DB cluster. To see if a DB instance is close to its concurrency limit, compare this value to <code>Aurora_pq_max_concurrent_requests</code> .
<code>Aurora_pq_request_throttled</code>	The number of times parallel query wasn't chosen due to the maximum number of concurrent parallel queries already running on a particular Aurora DB instance.

<code>Aurora_pq_request_not_chosen_long_trx</code>	The number of parallel query requests that used the nonparallel query processing path, due to the query being started inside a long-running transaction. An EXPLAIN statement can increment this counter even though the query isn't actually performed.
<code>Aurora_pq_request_not_chosen_unsupported_access</code>	The number of parallel query requests that use the nonparallel query processing path because the WHERE clause doesn't meet the criteria for parallel query. This result can occur if the query doesn't require a data-intensive scan, or if the query is a DELETE or UPDATE statement.
<code>Aurora_pq_request_not_chosen_column_bit</code>	The number of parallel query requests that use the nonparallel query processing path because of an unsupported data type in the list of projected columns.
<code>Aurora_pq_request_not_chosen_column_geom</code>	The number of parallel query requests that use the nonparallel query processing path because the table has columns with the GEOMETRY data type. For information about Aurora MySQL versions that remove this limitation, see Upgrading parallel query clusters to Aurora MySQL version 3 (p. 893) .
<code>Aurora_pq_request_not_chosen_column_lob</code>	The number of parallel query requests that use the nonparallel query processing path because the table has columns with a LOB data type, or VARCHAR columns that are stored externally due to the declared length. For information about Aurora MySQL versions that remove this limitation, see Upgrading parallel query clusters to Aurora MySQL version 3 (p. 893) .
<code>Aurora_pq_request_not_chosen_column_virtual</code>	The number of parallel query requests that use the nonparallel query processing path because the table contains a virtual column.
<code>Aurora_pq_request_not_chosen_custom_charset</code>	The number of parallel query requests that use the nonparallel query processing path because the table has columns with a custom character set.
<code>Aurora_pq_request_not_chosen_fast_ddl</code>	The number of parallel query requests that use the nonparallel query processing path because the table is currently being altered by a fast DDL ALTER Statement.
<code>Aurora_pq_request_not_chosen_full_text_index</code>	The number of parallel query requests that use the nonparallel query processing path because the table has full-text indexes.
<code>Aurora_pq_request_not_chosen_index_hint</code>	The number of parallel query requests that use the nonparallel query processing path because the query includes an index hint.

<code>Aurora_pq_request_not_chosen_innodb_table</code>	The number of parallel query requests that use the nonparallel query processing path because the table uses an unsupported InnoDB row format. Aurora parallel query only applies to the COMPACT, REDUNDANT, and DYNAMIC row formats.
<code>Aurora_pq_request_not_chosen_no_where_clause</code>	The number of parallel query requests that use the nonparallel query processing path because the query doesn't include any WHERE clause.
<code>Aurora_pq_request_not_chosen_range_scan</code>	The number of parallel query requests that use the nonparallel query processing path because the query uses a range scan on an index.
<code>Aurora_pq_request_not_chosen_row_length</code>	The number of parallel query requests that use the nonparallel query processing path because the total combined length of all the columns is too long.
<code>Aurora_pq_request_not_chosen_temporary_table</code>	The number of parallel query requests that use the nonparallel query processing path because the query refers to temporary tables that use the unsupported MyISAM or memory table types.
<code>Aurora_pq_request_not_chosen_tx_isolation</code>	The number of parallel query requests that use the nonparallel query processing path because the query uses an unsupported transaction isolation level. On reader DB instances, parallel query only applies to the REPEATABLE READ and READ COMMITTED isolation levels.
<code>Aurora_pq_request_not_chosen_update_delete</code>	The number of parallel query requests that use the nonparallel query processing path because the query is part of an UPDATE or DELETE statement.

How parallel query works with SQL constructs

In the following section, you can find more detail about why particular SQL statements use or don't use parallel query. This section also details how Aurora MySQL features interact with parallel query. This information can help you diagnose performance issues for a cluster that uses parallel query or understand how parallel query applies for your particular workload.

The decision to use parallel query relies on many factors that occur at the moment that the statement runs. Thus, parallel query might be used for certain queries always, never, or only under certain conditions.

Tip

When you view these examples in HTML, you can use the **Copy** widget in the upper-right corner of each code listing to copy the SQL code to try yourself. Using the **Copy** widget avoids copying the extra characters around the `mysql>` prompt and `->` continuation lines.

EXPLAIN statement

As shown in examples throughout this section, the `EXPLAIN` statement indicates whether each stage of a query is currently eligible for parallel query. It also indicates which aspects of a query can be pushed down to the storage layer. The most important items in the query plan are the following:

- A value other than `NULL` for the `key` column suggests that the query can be performed efficiently using index lookups, and parallel query is unlikely.
- A small value for the `rows` column (a value not in the millions) suggests that the query isn't accessing enough data to make parallel query worthwhile. This means that parallel query is unlikely.
- The `Extra` column shows you if parallel query is expected to be used. This output looks like the following example.

```
Using parallel query (A columns, B filters, C exprs; D extra)
```

The `columns` number represents how many columns are referred to in the query block.

The `filters` number represents the number of `WHERE` predicates representing a simple comparison of a column value to a constant. The comparison can be for equality, inequality, or a range. Aurora can parallelize these kinds of predicates most effectively.

The `exprs` number represents the number of expressions such as function calls, operators, or other expressions that can also be parallelized, though not as effectively as a filter condition.

The `extra` number represents how many expressions can't be pushed down and are performed by the head node.

For example, consider the following `EXPLAIN` output.

```
mysql> explain select p_name, p_mfgr from part
-> where p_brand is not null
-> and upper(p_type) is not null
-> and round(p_retailprice) is not null;
```

```
+----+-----+-----+...+-----+
+-----+-----+-----+-----+
| id | select_type | table |...| rows      | Extra
|     |             |       |   |
+-----+-----+...+-----+
| 1 | SIMPLE      | part  |...| 20427936 | Using where; Using parallel query (5 columns, 1
| filters, 2 exprs; 0 extra) |
+-----+-----+...+-----+
+-----+
```

The information from the `Extra` column shows that five columns are extracted from each row to evaluate the query conditions and construct the result set. One `WHERE` predicate involves a filter, that is, a column that is directly tested in the `WHERE` clause. Two `WHERE` clauses require evaluating more complicated expressions, in this case involving function calls. The `0 extra` field confirms that all the operations in the `WHERE` clause are pushed down to the storage layer as part of parallel query processing.

In cases where parallel query isn't chosen, you can typically deduce the reason from the other columns of the `EXPLAIN` output. For example, the `rows` value might be too small, or the `possible_keys` column might indicate that the query can use an index lookup instead of a data-intensive scan. The following example shows a query where the optimizer can estimate that the query will scan only a small number of rows. It does so based on the characteristics of the primary key. In this case, parallel query isn't required.

```
mysql> explain select count(*) from part where p_partkey between 1 and 100;
+----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type  | possible_keys | key      | key_len | ref   | rows  |
|     |             |       | range | PRIMARY      | PRIMARY  | 4        | NULL  | 99    |
|     |             |       |       | Using where; Using index |
+-----+-----+-----+-----+-----+-----+-----+-----+
```

The output showing whether parallel query will be used takes into account all available factors at the moment that the `EXPLAIN` statement is run. The optimizer might make a different choice when the query is actually run, if the situation changed in the meantime. For example, `EXPLAIN` might report that a statement will use parallel query. But when the query is actually run later, it might not use parallel query based on the conditions then. Such conditions can include several other parallel queries running concurrently. They can also include rows being deleted from the table, a new index being created, too much time passing within an open transaction, and so on.

WHERE clause

For a query to use the parallel query optimization, it *must* include a `WHERE` clause.

The parallel query optimization speeds up many kinds of expressions used in the `WHERE` clause:

- Simple comparisons of a column value to a constant, known as *filters*. These comparisons benefit the most from being pushed down to the storage layer. The number of filter expressions in a query is reported in the `EXPLAIN` output.
- Other kinds of expressions in the `WHERE` clause are also pushed down to the storage layer where possible. The number of such expressions in a query is reported in the `EXPLAIN` output. These expressions can be function calls, `LIKE` operators, `CASE` expressions, and so on.
- Certain functions and operators aren't currently pushed down by parallel query. The number of such expressions in a query is reported as the `extra` counter in the `EXPLAIN` output. The rest of the query can still use parallel query.

- While expressions in the select list aren't pushed down, queries containing such functions can still benefit from reduced network traffic for the intermediate results of parallel queries. For example, queries that call aggregation functions in the select list can benefit from parallel query, even though the aggregation functions aren't pushed down.

For example, the following query does a full-table scan and processes all the values for the `P_BRAND` column. However, it doesn't use parallel query because the query doesn't include any `WHERE` clause.

```
mysql> explain select count(*), p_brand from part group by p_brand;
+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows |
|    |             |       |      |               |     |         |    |      |
+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE      | part  | ALL  | NULL          | NULL | NULL    | NULL | 20427936 |
|   |              |       |      | Using temporary; Using filesort |
+-----+-----+-----+-----+-----+-----+
```

In contrast, the following query includes `WHERE` predicates that filter the results, so parallel query can be applied:

```
mysql> explain select count(*), p_brand from part where p_name is not null
      -> and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000
      -> group by p_brand;
+-----+-----+
| id | ... | rows      | Extra
|    |     |           |      |
+-----+-----+
| 1 | ... | 20427936 | Using where; Using temporary; Using filesort; Using parallel query (5
|   |       |           | columns, 1 filters, 2 exprs; 0 extra) |
+-----+-----+
```

If the optimizer estimates that the number of returned rows for a query block is small, parallel query isn't used for that query block. The following example shows a case where a greater-than operator on the primary key column applies to millions of rows, which causes parallel query to be used. The converse less-than test is estimated to apply to only a few rows and doesn't use parallel query.

```
mysql> explain select count(*) from part where p_partkey > 10;
+-----+-----+
| id | ... | rows      | Extra
|    |     |           |      |
+-----+-----+
| 1 | ... | 20427936 | Using where; Using parallel query (1 columns, 1 filters, 0 exprs; 0
|   |       |           | extra) |
+-----+-----+
```

```
mysql> explain select count(*) from part where p_partkey < 10;
+-----+-----+
| id | ... | rows      | Extra
|    |     |           |      |
+-----+-----+
```

```
| 1 |...| 9 | Using where; Using index |  
+---+---+-----+
```

Data definition language (DDL)

Before Aurora MySQL version 3, parallel query is only available for tables for which no fast data definition language (DDL) operations are pending. In Aurora MySQL version 3, you can use parallel query on a table at the same time as an instant DDL operation. Instant DDL in Aurora MySQL version 3 replaces the fast DDL feature in Aurora MySQL versions 1 and 2. For information about instant DDL, see [Instant DDL \(Aurora MySQL version 3\) \(p. 832\)](#).

Column data types

In Aurora MySQL version 3, parallel query can work with tables containing columns with data types `TEXT`, `BLOB`, `JSON`, and `GEOMETRY`. It can also work with `VARCHAR` and `CHAR` columns with a maximum declared length longer than 768 bytes. If your query refers to any columns containing such large object types, the additional work to retrieve them does add some overhead to query processing. In that case, check if the query can omit the references to those columns. If not, run benchmarks to confirm if such queries are faster with parallel query turned on or turned off.

Before Aurora MySQL version 3, parallel query has these limitations for large object types:

In these earlier versions, `TEXT`, `BLOB`, `JSON`, and `GEOMETRY` data types aren't supported with parallel query. A query that refers to any columns of these types can't use parallel query.

In these earlier versions, variable-length columns (`VARCHAR` and `CHAR` data types) are compatible with parallel query up to a maximum declared length of 768 bytes. A query that refers to any columns of the types declared with a longer maximum length can't use parallel query. For columns that use multibyte character sets, the byte limit takes into account the maximum number of bytes in the character set. For example, for the character set `utf8mb4` (which has a maximum character length of 4 bytes), a `VARCHAR(192)` column is compatible with parallel query but a `VARCHAR(193)` column isn't.

Partitioned tables

You can use partitioned tables with parallel query in Aurora MySQL version 3. Because partitioned tables are represented internally as multiple smaller tables, a query that uses parallel query on a nonpartitioned table might not use parallel query on an identical partitioned table. Aurora MySQL considers whether each partition is large enough to qualify for the parallel query optimization, instead of evaluating the size of the entire table. Check whether the `Aurora_pq_request_not_chosen_small_table` status variable is incremented if a query on a partitioned table doesn't use parallel query when you expect it to.

For example, consider one table partitioned with `PARTITION BY HASH (column) PARTITIONS 2` and another table partitioned with `PARTITION BY HASH (column) PARTITIONS 10`. In the table with two partitions, the partitions are five times as large as the table with ten partitions. Thus, parallel query is more likely to be used for queries against the table with fewer partitions. In the following example, the table `PART_BIG_PARTITIONS` has two partitions and `PART_SMALL_PARTITIONS` has ten partitions. With identical data, parallel query is more likely to be used for the table with fewer big partitions.

```
mysql> explain select count(*), p_brand from part_big_partitions where p_name is not null  
      ->      and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000 group  
      by p_brand;  
+-----+-----+-----+  
+-----+-----+-----+  
| id | select_type | table           | partitions | Extra          |  
+-----+-----+-----+
```

```
+-----+-----+
+-----+
| 1 | SIMPLE      | part_big_partitions | p0,p1      | Using where; Using temporary; Using
parallel query (4 columns, 1 filters, 1 exprs; 0 extra; 1 group-by, 1 aggrs) |
+-----+-----+
+
mysql> explain select count(*), p_brand from part_small_partitions where p_name is not null
      ->      and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000 group
by p_brand;
+-----+-----+
+-----+
| id | select_type | table           | partitions          | Extra
|
+-----+-----+
+-----+
| 1 | SIMPLE      | part_small_partitions | p0,p1,p2,p3,p4,p5,p6,p7,p8,p9 | Using where;
Using temporary |
+-----+-----+
+-----+
```

Aggregate functions, GROUP BY clauses, and HAVING clauses

Queries involving aggregate functions are often good candidates for parallel query, because they involve scanning large numbers of rows within large tables.

In Aurora MySQL 3, parallel query can optimize aggregate function calls in the select list and the `HAVING` clause.

Before Aurora MySQL 3, aggregate function calls in the select list or the `HAVING` clause aren't pushed down to the storage layer. However, parallel query can still improve the performance of such queries with aggregate functions. It does so by first extracting column values from the raw data pages in parallel at the storage layer. It then transmits those values back to the head node in a compact tuple format instead of as entire data pages. As always, the query requires at least one `WHERE` predicate for parallel query to be activated.

The following simple examples illustrate the kinds of aggregate queries that can benefit from parallel query. They do so by returning intermediate results in compact form to the head node, filtering nonmatching rows from the intermediate results, or both.

```
mysql> explain select sql_no_cache count(distinct p_brand) from part where p_mfgr =
'Manufacturer#5';
+-----+...+
| id | ...| Extra
+-----+...+
| 1 | ...| Using where; Using parallel query (2 columns, 1 filters, 0 exprs; 0 extra) |
+-----+...+
mysql> explain select sql_no_cache p_mfgr from part where p_retailprice > 1000 group by
p_mfgr having count(*) > 100;
+-----+...
+
| id | ...| Extra
|
+-----+...
+
| 1 | ...| Using where; Using temporary; Using filesort; Using parallel query (3 columns, 0
filters, 1 exprs; 0 extra) |
```

```
+----+...
+-----+
+
```

Function calls in WHERE clause

Aurora can apply the parallel query optimization to calls to most built-in functions in the `WHERE` clause. Parallelizing these function calls offloads some CPU work from the head node. Evaluating the predicate functions in parallel during the earliest query stage helps Aurora minimize the amount of data transmitted and processed during later stages.

Currently, the parallelization doesn't apply to function calls in the select list. Those functions are evaluated by the head node, even if identical function calls appear in the `WHERE` clause. The original values from relevant columns are included in the tuples transmitted from the storage nodes back to the head node. The head node performs any transformations such as `UPPER`, `CONCATENATE`, and so on to produce the final values for the result set.

In the following example, parallel query parallelizes the call to `LOWER` because it appears in the `WHERE` clause. Parallel query doesn't affect the calls to `SUBSTR` and `UPPER` because they appear in the select list.

```
mysql> explain select sql_no_cache distinct substr(upper(p_name),1,5) from part
      -> where lower(p_name) like '%cornflower%' or lower(p_name) like '%goldenrod%';
+----+...
+
| id | ... | Extra
  |
+----+...
+
| 1 | ... | Using where; Using temporary; Using parallel query (2 columns, 0 filters, 1
  exprs; 0 extra) |
+----+...
+
+
```
